WELCOME MESSAGE FROM PRESIDENT

On behalf of the Asia Pacific Signal and Information Processing Association (APSIPA), it is my great pleasure and honor to welcome all of you to the APSIPA Annual Summit and Conference (ASC), held in Taipei from October 31 through November 3, 2023. This is the 15th APSIPA ASC and the first ASC that I attend physically after the COVID-19 pandemic.

APSIPA was founded in 2009. It was targeted to cover signal and information processing, which is among the most growing research fields, in the most growing region of Asia Pacific. Since then, we have had APSIPA ASC, our flagship conference, every year in various sites in this region. In the past 15 years, we have seen steady growth in paper submissions and participants, even during the pandemic.

APSIPA now has more than one thousand members in total. Local chapters have been established in Japan, Taiwan, USA, and Singapore. We are now reaching out to developing countries, in particular ASEAN countries. We organized workshops in Hanoi, Vietnam, and Bandung, Indonesia, to attract papers to be presented in APSIPA ASC. We also provide financial support to attend the conference. As a result, a significant number of researchers participate from these countries.

The organizers of APSIPA ASC 2023 have worked very hard to make it successful. I would like to express my greatest appreciation and gratitude to the organizers led by General Co-Chairs, Jin-Ming Guo, Gwo-Giun Lee, Shih-Fu Chang, and Anthony Kuh. I believe their hard work will be paid off when the conference becomes a great experience for everyone. Eight technical committees (TCs) have also committed to organizing sessions, attracting papers, and overseeing the review process. The conference has a variety of programs including Winter School, Industrial Forum, and Women's Forum, which are organized by APSIPA VPs and BoG members to enhance diversity. In my personal experience, APSIPA provides an invaluable network through a variety of technical and regional areas, and we feel at home during the conference. I hope this tradition continues and is passed on to the future generation.

Tatsuya Kawahara
President, APSIPA (2023-2024)

WELCOME MESSAGE
FROM GENERAL CO-CHAIRS

Dear Esteemed Colleagues, Participants, and Friends,

It is our immense pleasure to extend a warm and hearty welcome to all of you to the 2023 Asia-Pacific Signal and Information Processing Association Annual Summit and Conference (APSIPA ASC 2023). This year, our prestigious event takes place from October 31st to November 3rd at the Taipei International Convention Center (TICC), situated in the vibrant heart of Taipei.

As we embark on this exciting journey, we recognize the extraordinary circumstances under which we convene once again. The global pandemic has presented unprecedented challenges, and our gathering for APSIPA ASC 2023 marks a significant milestone as the second APSIPA ASC conference held since the world began its journey towards recovery. We are truly delighted to welcome you all back and to witness the resilience and dedication of our global community as we come together to explore, discuss, and share the most cutting-edge research findings in the field of signal and information processing.

This year's conference program promises to be both intellectually stimulating and diverse, offering a wide range of opportunities for engagement. We have curated a lineup that includes four captivating keynote speeches by distinguished experts, an engaging industrial forum to bridge the gap between academia and industry, an empowering women's forum to celebrate diversity and inclusion in our field, five instructive tutorial sessions, and an immersive winter school program for students and researchers. The caliber of submissions for APSIPA ASC 2023 has been remarkable, with 532 contributions received from scholars and researchers representing different corners of the globe. After rigorous evaluation, we are thrilled to announce that 392 of these submissions have been accepted for presentation.

We extend our heartfelt gratitude to all participants, colleagues, and friends who have contributed to the success of this event. Your unwavering support has played a pivotal role in ensuring the smooth organization of this conference, and we are deeply appreciative of your commitment to advancing our shared goals.

Beyond the enriching academic exchanges and collaborative opportunities that await, we encourage you to take the time to explore the enchanting city of Taipei. Known for its blend of modernity and tradition, Taipei offers a unique cultural experience that is not to be missed. We hope that you will find moments of inspiration, connection, and rejuvenation throughout your stay.

In closing, we wish you a memorable and productive experience at APSIPA ASC 2023. May this conference be a catalyst for new insights, meaningful connections, and lasting memories. Together, we will continue to push the boundaries of knowledge and innovation in signal and information processing.

Welcome to APSIPA ASC 2023!

Warm regards,

Jing-Ming Guo, Gwo-Giun Lee, Shih-Fu Chang, Anthony Kuh

General Co-Chairs, APSIPA ASC 2023

WELCOME MESSAGE FROM TPC CO-CHAIRS

On behalf of the Technical Program Committee, we welcome you to Asia-Pacific Signal and Information Processing Association Annual Summit and Conference (APSIPA ASC) 2023. The conference is being held as a hybrid event at Taipei International Conventional Center, Taiwan from October 31 to November 3, 2023.

Founded in 2009, APSIPA ASC has been the annual conference organized by APSIPA to promote research and education in signal processing, information technology, and communications. APSIPA ASC 2023 inherits the tradition of previous conferences in putting together a variety of technical elements, including tutorials, keynotes, special/regular sessions, winter schools, industrial forums, overview sessions, women forums and best paper competitions, in a rich technical program for leading experts from around the world to disseminate and exchange their latest research outcomes. The theme of APSIPA ASC 2023 is "Prevalence of Artificial Intelligence with Signal and Information Processing."

PROGRAM HIGHLIGHTS

This year, we received from 21 countries/regions a total of 532 submissions, of which 395 were accepted through the single-blind review process managed by 115 Area Chairs and 616 reviewers. The accepted papers are organized into 46 oral sessions and 5 poster sessions. The oral sessions include 32 thematic Special Sessions, the papers of which were reviewed in the same way as regular papers.

Apart from the technical sessions, 4 outstanding keynote speakers have been invited to anchor the conference by sharing their perspectives on the forefront developments and trending topics around the conference theme:

- Wan-Chi Siu, The Hong Kong Polytechnic University, Hong Kong: "Deep Learning Latent Space for Super-Resolution with Extension to other Signal Processing Applications."
- Mark Hong-Yuan Liao, Academia Sinica, Taiwan: "From YOLOv4 to YOLOv7."
- TY Lin, MediaTek Inc., Taiwan: "The Impact of Edge AI – Opportunities and Challenges."
- Chiori Hori, Mitsubishi Electric Research Laboratory, USA: "Scene-aware Interaction for Human-Robot Communication."

To catch up with most recent active research, the Tutorial Chairs have selected 5 tutorials offered by leading experts in the APSIPA community:

- Advancements in AI: Transformers, Media Forensics and Cybersecurity.
- Defending against Misinformation in the Wild.
- Deep learning beyond curve fitting - Understanding bias and fairness in Computer Vision in the era of DALL-E and chatGPT.
- Advances in Psychoacoustics and Machine Learning towards Objective Speech Intelligibility Evaluation.

- Spoofing Face Recognition Systems with Adversarial Examples: Challenges and Countermeasures.

Moreover, APSIPA ASC 2023 follows the last few editions of APSIPA ASC to feature a Winter School on Generative AI Techniques for Signal and Information Processing Applications, inviting 5 renowned speakers from both academia and industry to address emerging topics on

- Deep Regression for Spectral Mapping with Applications to Speech Enhancement, Source Separation and Speech Dereverberation.
- Metaverse as AI Embodiment: Techniques, Impact, and Research Opportunities.
- Deep Learning in Image Processing and Computer Vision.
- How far are we from a speech version of ChatGPT?
- Energy-Efficient Generative AI Future: Low-Power Applications of ADI Max78000.

There are other interesting forums for you to learn fascinating insights into real-world problems of interest to industry. These forums offer opportunities for the conference participants to interact with our industry leaders.

AWARDS

To recognize high-quality and important research works, 6 top papers have been recommended by Area Chairs and Reviewers to compete for Best Paper Awards. These papers will be presented in the Best Paper Competition session, with the winners selected on-site by an award committee. Additionally, this year, the Technical Program Chairs chose 5 reviewers according to the recommendations from Area Chairs for Best Reviewer Awards. These awards will be presented during the banquet on Thursday evening.

ACKNOWLEDGEMENT

Last but not least, the conference would not have been successful without the contributions of every volunteer. We are deeply indebted to the voluntary services from Area Chairs and Reviewers. We are also very grateful to our patrons for their financial and/or technical sponsorships. We also like to thank every organizing committee member of APSIPA ASC 2023 for their commitment and help along the way, and the staff of the Conference Management for their assistance in organizing the conference. Of course, we cannot thank enough every author and participant. Without them, there is no point of holding this conference.

We hope that you will have an enjoyable and indelible experience at APSIPA ASC 2023.

APSIPA ASC 2023 Technical Program Chairs,

Regular Sessions: Hsin-Min Wang, Wen-Hsiao Peng, Chia-Hung Yeh, Jia-Ching Wang, Yu-Chao Dai, Beth Jelfs, Jen-Tzung Chien, Minoru Kuribayashi, Jun Du, Hiroshi Tsutsui, Po-Chiang Lin, Chang-Su Kim

Special Sessions: Jian-Jiun Ding, Li-Wei Kang, Toshihisa Tanaka, Chee Seng Chan

Wen-Hsiao Peng, Hsin-Min Wang, Chia-Hung Yeh and Jia-Ching Wang,
APSIPA ASC 2023 Technical Program Chairs

ORGANIZING COMMITTEE

Honorary Co-Chairs

K. J. Ray Liu, University of Maryland, USA
C.-C. Jay Kuo, University of Southern California, USA
Haizhou Li, National University of Singapore, Singapore
Wan-Chi Siu, The Hong Kong Polytechnic University, Hong Kong
Hitoshi Kiya, Tokyo Metropolitan University, Japan

Advisory Committee Co-Chairs

Chung-Nan Lee, National Sun Yat-Sen University, Taiwan
Chung-Hsien Wu, National Cheng Kung University, Taiwan
Tatsuya Kawahara, Kyoto University, Japan
Woon-Seng Gan, Nanyang Technological University, Singapore
Min Wu, University of Maryland, USA

General Co-Chairs

Jing-Ming Guo, National Taiwan University of Science and Technology, Taiwan
Gwo-Giun Lee, National Cheng Kung University, Taiwan
Shih-Fu Chang, Columbia University, USA
Anthony Kuh, University of Hawaii at Manoa, USA

TPC Co-Chairs

Hsin-Min Wang, Academia Sinica, Taiwan
Wen-Hsiao Peng, National Yang Ming Chiao Tung University, Taiwan
Chia-Hung Yeh, National Taiwan Normal University, Taiwan
Jia-Ching Wang, National Central University, Taiwan
Yu-Chao Dai, Northwestern Polytechnical University, China (SIPTM)
Beth Jelfs, University of Birmingham, England (BioSiPS)
Jen-Tzung Chien, National Yang Ming Chiao Tung University, Taiwan (MLDA)
Minoru Kuribayashi, Tohoku University, Japan (MSF)
Jun Du, University of Science and Technology of China, China (SLA)
Hiroshi Tsutsui, Hokudai University, Japan (SPS)
Po-Chiang Lin, Yuan Ze University, Taiwan (WCN)
Chang-Su Kim, Korea University, Korea (IVM)

Finance Co-Chairs

Kun-Chih Chen, National Yang Ming Chiao Tung University, Taiwan

Tien-Ying Kuo, National Taipei University of Technology, Taiwan

Sayaka Shiota, Tokyo Metropolitan University, Japan

Plenary Co-Chairs

Kenneth Lam, The Hong Kong Polytechnic University, Hong Kong

Yih-Fang Huang, University of Notre Dame, USA

Special Session Co-Chairs

Jian-Jiun Ding, National Taiwan University, Taiwan

Li-Wei Kang, National Taiwan Normal University, Taiwan

Toshihisa Tanaka, Tokyo University of Agriculture and Technology, Japan

Chee Seng Chan, University of Malaya, Malaysia

Award Co-Chairs

Hsueh-Ming Hang, National Yang Ming Chiao Tung University, Taiwan

Ching-Te Chiu, National Tsing Hua University, Taiwan

Thomas Fang Zheng, Tsinghua University, China

Kosin Chamnongthai, King Mongkut's University of Technology Thonburi, Thailand

Antonio Ortega, University of Southern California, USA

Tutorial Co-Chairs

Guo-Shiang Lin, National Chin-Yi University of Technology, Taiwan

Kazuya Takeda, Nagoya University, Japan

KokSheik Wong, Monash University, Malaysia

Publicity Co-Chairs

Yin-Tsung Hwang, National Chung Hsing University, Taiwan

Chun-Shien Lu, Academia Sinica, Taiwan

Sanghoon Lee, Yonsei University, Korea

Bonnie Ngai-Fong Law, The Hong Kong Polytechnic University, Hong Kong

Publication Co-Chairs

Ting-Lan Lin, National Taipei University of Technology, Taiwan

Yoshinobu Kajikawa, Kansai University, Japan

Zhaoxia Yin, East China Normal University, China

Industrial Forum Co-Chairs

Chii-Wann Lin, Industrial Technology Research Institute, Taiwan

Wen-Liang Hwang, Academia Sinica, Taiwan

Arun Kumar Sangaiah, National Yunlin University of Science and Technology, Taiwan

Seishi Takamura, NTT Computer and Data Science Laboratories/Hosei University, Japan

Sponsorship and Exhibition Co-Chairs

Kevin Tseng, Fuhong Co., Ltd. (iStuNet), Taiwan

Zhenxing Qian, Fudan University, China

Wei Lu, Sun Yat-sen University, China

Local Arrangement Co-Chairs

Pei-Yun Tsai, National Central University, Taiwan

Chih-Hsien Hsia, National Ilan University, Taiwan

Overview Section Co-Chairs

Chuan-Yu Chang, National Yunlin University of Science and Technology, Taiwan

Tin-Yu Wu, National Pingtung University of Science and Technology, Taiwan

Winter School Co-Chairs

Mu-Yen Chen, National Cheng Kung University, Taiwan

Mingyi He, Northwestern Polytechnical University, China

Wednesday, November 1, 2023	08:00-17:00
Thursday, November 2, 2023	08:00-17:00
Friday, November 3, 2023	08:30-12:00

EXHIBITION

Lobby, 1F

Open Hours:

Tuesday, October 31, 2023	09:00-17:30
Wednesday, November 1, 2023	09:00-17:00
Thursday, November 2, 2023	09:00-16:45
Friday, November 3, 2023	09:00-12:00

BADGE

Please wear and clearly display your name badge to attend the conference at all times. All participants will receive the badge upon registration. Access to the conference venue will not be granted without a proper name badge.

CONFERENCE POLICY

- ✓ Smoking is prohibited at all times in the conference rooms and the entire building.
- ✓ Please switch your mobile phone off or to vibration mode during all sessions.
- ✓ No photography or recording are allowed in any sessions.

LANGUAGE

The official language of the conference is English, which will be used in all presentations and printed materials.

LUNCH/COFFEE BREAK

Lunch box and refreshment will be served at 1F (outside 101AB and 101CD meeting room).

SOCIAL PROGRAMS

Welcome Reception

Date/Time: 17:30-20:00, October 31

Venue: Banquet Hall, 3F, TICC

Banquet

Date/Time: 18:30-21:00, Nov. 2

Venue: Banqueting Ballroom, 3F, Silks Palace

**Shuttle buses will be provided at 17:00.*

INSTRUCTIONS FOR ORAL PRESENTERS

Upload Presentation Files

All the presenters are required to use the laptops provided by the organizer for presentation. If using a PowerPoint presentation, please save the file in USB and upload it to the conference laptop in the meeting room 15 minutes before your session starts. Our staff will assist you to save your file. We highly recommend you to bring two copies of your file as a backup.

Presentation Time

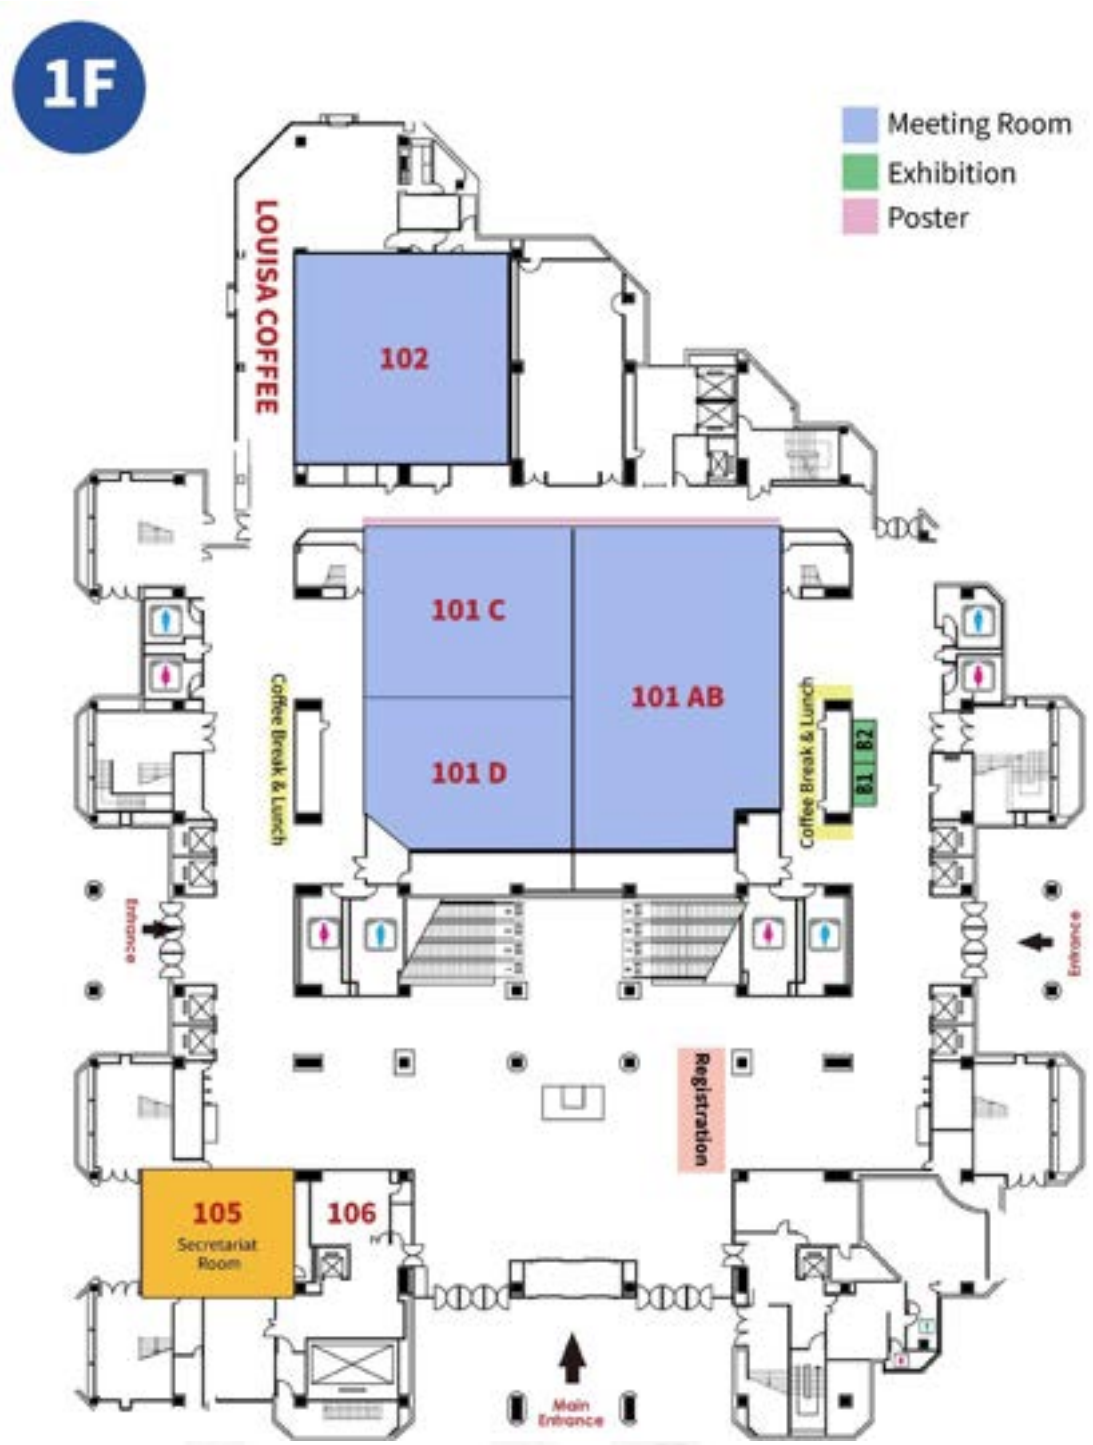
Oral Presentation: 15 minutes presentation+5 minutes Q&A, total 20 minutes.

INSTRUCTIONS FOR POSTER PRESENTERS

- The poster board in portrait format is reserved for each poster.
- Authors shall prepare their posters in standard A0 size (841mm x 1189 mm) and mount it on the poster board.
- The presenting author has to present the work in front of the poster during the poster session.
- Poster Schedule:

Assembling Date/Time

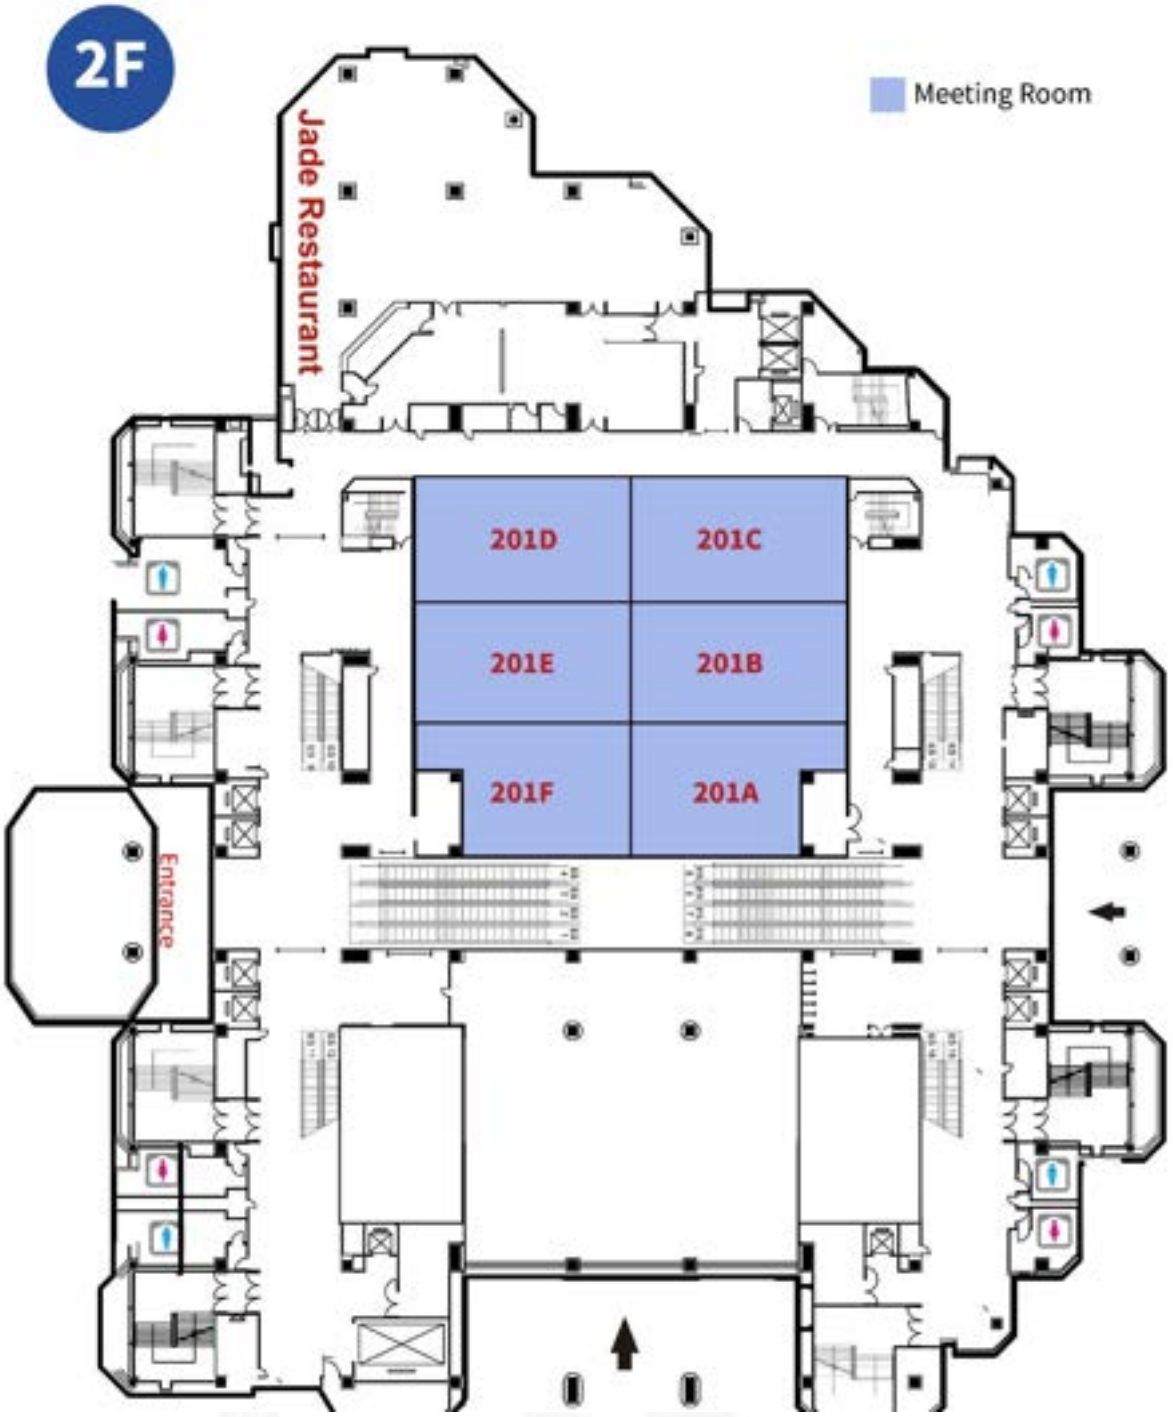
Poster Session I	09:00-10:20, Nov. 1
Poster Session II	13:30-15:00, Nov. 1
Poster Session III	08:00-09:00, Nov. 2
Poster Session IV	12:00-13:30, Nov. 2
Poster Session V	08:30-09:00, Nov. 3



Presenting Date/Time

Poster Session I	10:20-12:00, Nov. 1
Poster Session II	15:00-17:00, Nov. 1
Poster Session III	09:00-10:40, Nov. 2
Poster Session IV	13:30-15:30, Nov. 2
Poster Session V	09:00-10:40, Nov. 3

Removal Date/Time



Poster Session I	12:00-12:30, Nov. 1
Poster Session II	17:00-17:30, Nov. 1
Poster Session III	10:40-11:10, Nov. 2
Poster Session IV	15:30-16:00, Nov. 2
Poster Session V	10:40-11:10, Nov. 3

PROGRAM AT A GLANCE

October 31 (Tuesday)

Time / Location	101AB	101CD	102
09:30-11:30	[T01] Advancements in AI: Transformers, Media Forensics and Cybersecurity	[T02] Defending against Misinformation in the Wild	Winter School
11:30-13:00		Lunch	
13:00-15:00	[T03] Deep Learning Beyond Curve Fitting - Understanding Bias and Fairness in Computer Vision in the Era of DALL-E and chatGPT	[T04] Advances in Psychoacoustics and Machine Learning towards Objective Speech Intelligibility Evaluation	Winter School
15:00-15:30		Coffee Break	
15:30-17:30	[T05] Spoofing Face Recognition Systems with Adversarial Examples: Challenges and Countermeasures		Winter School
17:30-20:00		Welcome Reception (Banquet Hall, 3F, TICC)	

November 1 (Wednesday)

Time / Location	101AB	101C	101D	102	201A	201B
09:00 10:00	Opening Ceremony & Invited Talk for the APSIPA Sadaoki Furui Prize Paper Award (101AB)					
10:00 10:20	Coffee Break					
10:20 12:00	[A1] Biomedical Signal Processing and Systems	[B1] Data Analytics and Machine Learning	[C1] Deep Learning: Algorithm, Implementations, and Applications	[D1] Recent Advances on Speech Preprocessing in Multi-Speaker Scenarios	[E1] SLA-I: Speaker Recognition and Spoken Language Identification	[F1] SLA-II: Music Information Processing
12:00 13:30	[TC1] TC Meeting (SPS)	[TC2] TC Meeting (MSF)	[TC3] TC Meeting (BioSiPS)	[TC4] TC Meeting (SLA)	[TC5] TC Meeting (WCN)	[TC6] TC Meeting (IVM)
13:30 14:30	Keynote Speech I Prof. Wan-Chi Siu, The Hong Kong Polytechnic University, Hong Kong (101AB)					
14:30 15:00	Coffee Break					
15:00 17:00	[A2] IVM-1: Multimedia Content Analysis and Assessment	[B2] Advanced Biomedical Signal Processing (II): Brain Signal Processing and Analysis	[C2] Multimedia Security and Privacy in the Age of Deep Learning	[D2] The Intersection of AI and Computer Vision: Advancements and Opportunities	[IF1] Industrial Forum	[BS1] Best Paper Competition
17:30 21:30	BoG Meeting (Grand Hyatt Hotel)					

November 1 (Wednesday)

Time / Location	201C	201D	201E	201F	103 Hallway
09:00 10:00	Opening Ceremony & Invited Talk for the APSIPA Sadaoki Furui Prize Paper Award (101AB)				
10:00 10:20	Coffee Break				
10:20 12:00	[G1] Advanced Biomedical Signal Processing (I): Human Well-Being	[H1] Advanced Information Processing Technologies for Human and World	[I1] Selected Papers from APSIPA Workshop in Bandung, Indonesia (I)	[J1] Selected Papers from APSIPA Workshop in Hanoi, Vietnam (I)	[P1] Poster Session I
12:00 13:30	Lunch				
13:30 14:30	Keynote Speech I Prof. Wan-Chi Siu, The Hong Kong Polytechnic University, Hong Kong (101AB)				
14:30 15:00	Coffee Break				
15:00 17:00	[G2] Advanced Image and Video Processing Using Deep Learning	[H2] Advanced Learning-based Computer Vision Technologies	[I2] Physics-Inspired Image Restoration and Enhancement	[J2] IVM-2: Multimedia Generation and Synthesis	[P2] Poster Session II
17:30 21:30	BoG Meeting (Grand Hyatt Hotel)				

November 2 (Thursday)

Time / Location	101AB	101C	101D	102	201A	201B
09:00 10:40	[A3] SLA-III: Speech Emotion Recognition	[B3] Acoustic Scene Analysis and Signal Enhancement Based on Advanced Signal Processing and Machine Learning	[C3] Intelligent Recognition Applications	[D3] Signal and Information Processing Theory and Methods	[E3] SLA-IV: Speech Enhancement	[F3] SLA-V: Text-to-Speech and Voice Conversion
10:40 11:00	Coffee Break					
11:00 12:00	Keynote Speech II Prof. Hong-Yuan Liao, Academia Sinica, Taiwan (101AB)					
12:00 13:30	[WF] APSIPA Women Forum	Lunch		APSIPA Taiwan Chapter Annual Congress	Lunch	
13:30 15:30	[A4] IVM-3: Multimedia Representation and Identification	[B4] Innovative Technology on 3D Point Cloud and Image Processing	[C4] Machine Learning under Data-Constrained Conditions	[D4] Signal Processing and Artificial Intelligence in Biomedicine and Healthcare	[E4] Artificial Intelligence (AI) for Multimedia Processing and Applications	[F4] Emerging Trends in Privacy, Multimedia Security and Forensics: Deep Learning and AI Approaches
15:30 15:45	Coffee Break					
15:45 16:45	Keynote Speech III Mr. TY Lin, MediaTek, Taiwan (101AB)					
18:00 21:00	Banquet (Banqueting Ballroom, 3F, Silks Palace)					

November 2 (Thursday)

Time / Location	201C	201D	201E	201F	103 Hallway
09:00 10:40	[G3] Distributed and Multi-task Learning Algorithms and Applications	[H3] Recent Advances on Signal and Information Processing for Active Control of Sound	[I3] Selected Papers from APSIPA Workshop in Bandung, Indonesia (II)	[J3] Selected Papers from APSIPA Workshop in Hanoi, Vietnam (II)	[P3] Poster Session III
10:40 11:00	Coffee Break				
11:00 12:00	Keynote Speech II Prof. Hong-Yuan Liao, Academia Sinica, Taiwan (101AB)				
12:00 13:30	Lunch				
13:30 15:30	[G4] Intelligent Visual Data Processing, Analytics, and Representation	[H4] SLA-VI: Speech Recognition	[I4] New Frontiers in Biometric Authentication	[OS1] Overview Section (I)	[P4] Poster Session IV
15:30 15:45	Coffee Break				
15:45 16:45	Keynote Speech III Mr. TY Lin, MediaTek, Taiwan (101AB)

Life-Fellow IEEE

Deep Learning Latent Space for Super-Resolution with Extension to other Signal Processing Applications

In this presentation, we start with an elaboration of the mechanism of some deep learning techniques and the reasons of their success, which include attention mechanics and back projection structures for image super-resolution and enlightening, etc. A comparison of these techniques with conventional signal processing approaches will be given. We then gradually highlight the development of Generative Adversarial Network (GAN), StyleGAN, Diffusion Model, etc. to show that these represent a 2nd revolution on image to image processing and image manipulation problems, making use of the huge latent space, which resolves these problems with an initial prior or even turns these problems into a searching or retrieval exercise in the latent space. At the end of the presentation, fruitful demonstrations will be provided.

BIOGRAPHY

Prof. Wan-Chi Siu, PhD, DIC, Life-FIEEE, is Emeritus Professor (formerly Chair Professor, HoD (EIE) and Dean of Engineering Faculty) of Hong Kong Polytechnic University and Research Professor of Caritas Institute of Higher Education in Hong Kong. He is Life-Fellow of IEEE and was a PhD graduate (1984) of the Imperial College London, Vice President, Chair of Conference Board and core member of Board of Governors of the IEEE SP Society (2012-2014), and President (2017-2018) of APSIPA, and has been Guest Editor/Subject Editor/AE for IEEE Transactions on CAS, IP & CSVT, and Electronics Letters. He is an outstanding scholar with many awards, including Distinguished Presenter Award, the Best Teacher Award, the Best Faculty Researcher Award (twice) and IEEE Third Millennium Medal (2000). He was an APSIPA Distinguished Lecturer (2021-22), and an Advisor & Distinguished Scientist of the European research project SmartEN (offered by European Commissions). Prof. Siu has been Keynote Speaker and Invited Speaker of many conferences, published over 500 research papers (200 appeared in international journals such as IEEE Transactions on Image Processing) in DSP, transforms, fast algorithms, machine learning, deep learning, super-resolution imaging, 2D/3D video coding, object recognition and tracking, and organized IEEE society-sponsored flagship conferences as TPC Chair (ISCAS1997) and General Chair (ICASSP2003 and ICIP2010). He was an independent non-executive director (2000-2015) of a publicly-listed video surveillance company and chaired the First Engineering/IT Panel of the RAE (1992/93) in Hong Kong. Recently, he has been a member of the IEEE Educational Activities Board, the IEEE FourierAward for Signal Processing Committee (2017-2020), the Hong Kong RGC Engineering-JRS Panel (2020-2023), Hong Kong ASTRI Tech Review Panel (2006-2022) and some other IEEE technical committees.

IEEE Fellow

From YOLOv4 to YOLOv7

During 2018/1 – 2021/12, my research team conducted a research project with ELAN Electronics, a listed company in Hsinchu Science Park, on ``Smart City Traffic Flow Solutions'' case. To solve ELAN's expectation that the research team can calculate traffic parameters in real time at the edge (i.e., crossroads), so as to achieve the purpose of dynamically controlling traffic signs, my research team developed the world-famous real-time object detector – YOLOv4. From 2020 till now, various industries around the world, including medical systems, astronomy, biology, smart transportation, smart manufacturing and other fields, have adopted YOLOv4 to perform object detection in their respective fields. As of February 2023, the cumulative number of citations of YOLOv4 has exceeded 8,300 times. To continue maintaining the world's leading position and win glory for Taiwan, my research team released an advanced version of the object detection system – YOLOv7, in July 2022. In this talk, I will detail the development process of YOLOv4 and YOLOv7.

BIOGRAPHY

Mark Liao received his Ph.D. from Northwestern University, Evanston, Illinois, in 1990. He joined the Institute of Information Science, Academia Sinica, Taiwan in 1991. He received the Young Investigators' Award from Academia Sinica in 1998; the Distinguished Research Award from the National Science Council in 2003, 2010 and 2013; the Academia Sinica Investigator Award in 2010; the TECO Award from the TECO Foundation in 2016, and the 64th Academic Award from the Ministry of Education in 2020. His professional activities include: Editorial Board Member, IEEE Signal Processing Magazine (2010-13); Associate Editor, IEEE Transactions on Image Processing (2009-13), IEEE Transactions on Information Forensics and Security (2009-12), IEEE Transactions on Multimedia (1998-2001), ACM Computing Surveys (2018-2021). He is now a Senior Associate Editor of ACM Computing Surveys (2021-present). He has been a Fellow of the IEEE since 2013.

The Impact of Edge AI – Opportunities and Challenges

Analytic AI has improved our daily lives in scenarios such as data classification, detection, and recognition. The recent boom in generative AI will have an even greater impact in every aspect of our lives. Analytic AI displayed a trend where applications were initially run in the cloud and then migrated to edge devices for a better user experience. Most generative AI applications require much higher computing resources and are currently executed in the cloud. This keynote will explore the trend toward edge computing for analytic AI, and the opportunities and challenges for future generative AI.

BIOGRAPHY

TY received both his Bachelor's and Master's degrees from National Taiwan University. After completing his military service in the Navy, he joined MediaTek in 1999 as a digital signal processing (DSP) engineer. He was a founding member of the team behind MediaTek's DVD Player system-on-a-chip (SoC), which achieved a worldwide #1 share in 2002 with the most design awards of any global tier-one brand. Since 2004, TY has managed teams such as DTV SoC, Android TV, PQ engine, and computing platform architecture engineering. He currently leads MediaTek's central AI teams, where his responsibilities include AI processor design, AI software, and AI algorithm development for various product lines, including smartphones, smart TVs, smart cameras, automotive, and AIoT.

Chiori Hori

11:00-12:00, November 3

Senior Principal Research Scientist
Mitsubishi Electric Research Laboratory
USA

Scene-aware Interaction for Human-Robot Communication

Spoken dialog is a key modality for human-machine interaction. In the past, most dialog system research focused on filling values to be used in downstream tasks, such as booking a flight. Recent work has produced chatbots whose grounding in large language models enables them to chat more freely, responding to users reasonably in an open domain. However, such dialog systems cannot understand dynamic scenes in the real world, so they cannot have a conversation about what is happening in their surroundings. To develop machines that can carry on a conversation about objects and events happening around the machines or their users, dynamic scene-aware dialog technology is essential. In this talk, I introduce a new research target: a dialog system that can discuss dynamic scenes with humans. This work lies at the intersection of multiple avenues of research including natural language processing, computer vision, audio processing, and even radio frequency signal processing.

BIOGRAPHY

Dr. Chiori Hori is a Senior Principal Research Scientist at Mitsubishi Electric Research Laboratories (MERL) in Cambridge, MA, where she has worked since 2015. Her research is focused on multimodal scene-aware interaction technologies for human-robot communications. Prior to MERL, she spent eight years at the National Institute of Information and Communication Technology (NICT) in Japan, and before that she was a researcher at Carnegie Mellon University (CMU) and NTT Communication Science Laboratories. At NICT, she was the director of the Spoken Language Communication Laboratory, where she led multiple projects in network-based speech translation systems for the international consortium U-STAR. Dr. Hori has received several awards, including the 24th TELECOM System Technology Award in 2009, the International Cooperation Award from ITU-AJ in 2012, the DOCOMO Mobile Science Award for Social Science Sector in 2012, and the 58th Maejima Hisoka Award in 2013. She served on the editorial board of the journal Computer Speech and Language, and she was a technical committee member of the Speech and Language Processing Group of the IEEE Signal Processing Society. She received her Ph.D. degree from the Tokyo Institute of Technology.

INDUSTRIAL FORUM SPEAKERS

AI for Human Well-Being

15:00-17:00, November 1

Research Director & Associate Professor

Stefan Winkler

Asus Intelligent Cloud Services (AICS), Singapore

National University of Singapore (NUS), Singapore

Machine Learning for Healthcare Applications

Machine learning has shown tremendous promise across a broad range of domains. The healthcare environment is becoming increasingly ready to embrace these solutions, which have the potential to lower healthcare costs, identify more effective treatments, and facilitate prevention and early detection of diseases. However, the development of machine learning solutions for healthcare requires paying close attention to the ecosystem as well as the clinical workflow.

In this talk, I will share recent advances in machine learning, computer vision, and natural language processing that are driving innovation in medicine, including some example solutions. Finally, I will discuss challenges and future directions for machine learning in healthcare.

BIOGRAPHY

Stefan Winkler is Research Director of Asus Intelligent Cloud Services (AICS) as well as Adjunct Associate Professor at the National University of Singapore (NUS). Prior to that he was Deputy Director at AI Singapore. He also co-founded two start-ups (Genista and Opsis) and worked for a Silicon Valley company.

Dr. Winkler has a Ph.D. degree from the Ecole Polytechnique Fédérale de Lausanne (EPFL), Switzerland, and a Dipl.-Ing. (M.Eng./B.Eng.) degree from the University of Technology Vienna, Austria. He is an IEEE Fellow and has published over 150 papers. He has also contributed to international standards in VQEG, ITU, ATIS, VSF, and SCTE. His research interests include video processing, computer vision, machine learning, perception, and human-computer interaction.

15:00-17:00, November 1

Country Head

Karthi Madhavan

Tata Consultancy Services, Taiwan

AI - Global Trends and Opportunities

Traditionally, economic activity has been grouped into three buckets—production, transactions, and interactions—and technology had made significant inroads into each. Machines and factory technologies transformed production by augmenting and automating human labor during the Industrial Revolution more than 100 years ago, and evolved technologies have further amped up efficiencies on the manufacturing floor. Transactions have undergone many technological iterations over approximately the same time frame, including most recently digitization and, frequently, automation. Until recently, interactions, such as customer service, has experienced the least mature technological interventions. Generative AI is set to change that by undertaking interactions in a way that approximates human behavior closely and, in some cases, imperceptibly. That's not to say these tools are intended to work without human input and intervention. In many cases, they are most powerful in combination with humans, augmenting their capabilities and enabling them to get work done faster and better. This creates enormous and transformational possibilities in all facets of economic activity in the near future.

BIOGRAPHY

Karthi Madhavan is presently the Country Head of Tata Consultancy Services, Taiwan, ROC. He has over 28 years of experience in Business Operations Management and Growth, Delivery Unit Management, People Management and Coaching and International Business in IT and Services Sector across various geographies. Karthi holds a Bachelor's Degree with Distinction in Physics from The Madras Christian College and has advanced training in management and negotiation from premier institutes. He and his projects are recipient of many awards some of which are, The President of India Award for Best Use of IT, Governor's Award for EGovernance, World Bank Award, CSI All India Award for Excellence in IT and Asia Pac FT- Citi Urban Ingenuity Awards. Karthi is very passionate about education and he's an honorary member of the Management Council of Karnataka Industrial Training Institute (ITI). He is an invited speaker in many forums on Smart City, EGovernance programs and Digital Technologies and is actively involved in large scale transformational IT and social programs. He is an avid sports lover and loves golf and horse riding. He enjoys history, books, travelling and meeting new people.

Generative AI Techniques for Signal and Information Processing Applications

Professor

Chin-Hui Lee

Georgia Institute of Technology, USA

Deep Regression for Spectral Mapping with Applications to Speech Enhancement, Source Separation and Speech Dereverberation

In this lecture, we present a deep regression framework for solving classical signal processing and spectral mapping problems. Based on Komogorov's Representation Theorem (1957), a multivariate scalar function can be expressed exactly as a superposition of a finite number of inner functions embedded within another linear combination of inner functions. Cybenko (1989) developed a universal approximation theorem showing such a scalar function can be approximated by a superposition of sigmoid functions, inspiring a new wave of neural network algorithms. Barron (1993) later proved that the error in this universal approximation can be tightly bounded and related to the representation power of neural networks in learning theory. In order to make the mapping function learnable and computable for some practical applications, we cast the classical approximation problems into a nonlinear vector-to-vector regression setting using deep neural networks (DNNs) as mapping functions, such that the DNN parameters can be estimated with deep learning and big data configurations.

Many classical speech processing problems, such as enhancement, source separation and dereverberation, can be formulated as finding mapping functions to transform noisy input to clean output spectra. As a result, DNN-transformed speech usually exhibits a good quality and a clear intelligibility under adverse acoustic conditions. Finally, our proposed deep regression framework was also tested on recent challenging tasks in CHiME-2, CHiME-4, CHiME-5, CHiME-6, REVERB and DIHARD evaluations. Based on the top quality achieved in microphone-array based enhancement, separation and dereverberation, our teams often scored the lowest error rates in almost all the above-mentioned open evaluation scenarios.

BIOGRAPHY

Chin-Hui Lee is a professor at School of Electrical and Computer Engineering, Georgia Institute of Technology. Before joining academia in 2001, he had accumulated 20 years of industrial experience ending in Bell Laboratories, Murray Hill, as the Director of the Dialogue Systems Research Department. Dr. Lee is a Fellow of the IEEE and a Fellow of ISCA. He has published 30 patents and about 600 papers, with more than 55,000 citations and an h-index of about 80 on Google Scholar. He received numerous awards, including the Bell Labs President's Gold Award for speech recognition products in 1998. He won the SPS's 2006 Technical Achievement Award for "Exceptional Contributions to the Field of Automatic Speech Recognition''. In 2012 he gave an ICASSP plenary talk on the future of automatic speech recognition. In the same year he was awarded the ISCA Medal in Scientific Achievement for "pioneering and seminal contributions to the principles and practice of automatic speech and speaker recognition''. His two pioneering papers on deep regression accumulated over 2000 citations in recent years and won a Best Paper Award from IEEE Signal Processing Society in 2019.

Mario Koeppen

Kyushu Institute of Technology, Japan /, Applied Soft Computing

Metaverse as AI Embodiment: Techniques, Impact, and Research Opportunities

Born from the 1992 novel "Snow Crash" of Neal Stephenson as dystopian vision of a society where the depth of technological integration passed a threshold where the human can't distinguish anymore between its real-world identity and digital identity, that thing called metaverse has come into our technical reach. This is due to the rapid advances in sensing, computing, storing, communication and intelligent technologies that more and more thoroughly shape, influence and even condition our all daily life. Metaverse is a global concept and has been characterized by factors such as: identity (avatars), social interaction, immersion, low latency, diversity, anytime anywhere service, trading economy and civilization, to follow organizational principles of a society. It is not restricted to computer games. We can understand, and thus design, optimize, analyze, enrich etc. any large-scaled public service in terms of a metaverse model: transportation networks, smart city, the global food chain, video conferencing systems, to name a few. This way, metaverse also becomes a methodology. In this talk, after introducing above points on a more factual base and showing how well-known public infrastructures can in fact be modeled as a metaverse, and to what that might be good for, we will consider the way of integrating AI and Metaverse. There are essentially three tiers. Tier 1 is the use of AI to design the metaverse. For the artists and developer, the design and functional configuration of digital models targeting a higher and higher level of realism or believability is still a burden, time consuming, experience and skill-based. It is still a highly specific activity where the task can be often only understood in the technical jargon of computer graphics designer. Here, AI already helped to design the tools to create digital assets, and we will show a few examples: auto-posing balanced characters trained by DL, motion extraction from videos, optimization of mesh data controlling animations and scene visualizations, or the creation of compensating dynamic corrections (aka morphs). It is still a highly specific application domain, and for a good reason, in the roadmap of text-based generative AI techniques as there are: text to text, text to image, text to video, text to 3D model, it has been put at the last position Hope is that we can clarify why that is so. Tier 2, it is the opposite way, the Metaverse assists the development, learning and training of AI and related scientific investigations. This refers to a common understanding of metaverse as simulation and visualization tool. But it's a bit more. It refers to the convergence of parallelization multiple metaverse instances and a continuously increasing level of realism, subjective immersion feeling, and phyiscal correctness with feasible compensations. Most typical case here is the design of training situations for DL training, that often needs a huge corpus of data that can't be created from real-

world situations. Uses are: for object detection from realistically rendered scenes that can be interactively explored, or for challenges to develop robot arm control in a factory environment, or to optimize the control or response to influencing factors in smart farming. Tier 3 is to equip the metaverse with AI. This is a common need in computer games to design the behavior of so-called NPCs (Non-Playable Characters) but otherwise still a vision, and only naive approaches like NPC chatbots have been conceptualized so far. Still, AI is non-divisible, has no identity, and also the idea to give them a body, allow them to communicate, to differentiate, to, well, evolve, to link to real-world processes and take controls might give the one or other the idea that we also should better think twice about what we are doing before we are doing so. But in summary, we are still in a situation where most of the people have no practical experience of a metaverse, and if so hardly find the time needed to spend in it while facing a steep learning curve, apart from simply just not being interested, worried about health impact, diminishing social life activities, become manipulated and distracted from solving the true problems of humankind, it has been shown that the whole concept of metaverse is actually counterfeiting such concerns, and poses a lot of scientific and engineering challenges and opportunities for many years to come.

BIOGRAPHY

Mario Köppen was born in 1964. He studied physics at the Humboldt-University of Berlin and received his master degree in solid state physics in 1991. Afterwards, he worked as scientific assistant at the Central Institute for Cybernetics and Information Processing in Berlin and changed his main research interests to image processing and neural networks. From 1992 to 2006, he was working with the Fraunhofer Institute for Production Systems and Design Technology. He continued his works on the industrial applications of image processing, pattern recognition, and soft computing, esp. evolutionary computation. During this period, he achieved the doctoral degree at the Technical University Berlin with his thesis works: "Development of an intelligent image processing system by using soft computing" with honors. He has published more than 150 peer-reviewed papers in conference proceedings, journals and books and was active in the organization of various conferences as chair or member of the program committee, incl. the WSC on-line conference series on Soft Computing in Industrial Applications, and the HIS conference series on Hybrid Intelligent Systems. He is founding member of the World Federation of Soft Computing, and also Editor of the Applied Soft Computing journal. In 2006, he became JSPS fellow at the Kyushu Institute of Technology in Japan, and in 2008 Professor at the Network Design and Research Center (NDRC) and 2013 Professor at the Graduate School of Creative Informatics of the Kyushu Institute of Technology, where he is conducting now research in the fields of multi-objective and relational optimization, digital convergence and multimodal content management.

Editor-In-Chief

Chunghui Kuo

Journal of Imaging Science and Technology, Society for Imaging Science and Technology

Deep Learning in Image Processing and Computer Vision

The fundamental question for machine learning is to find a rich class of functionals which can map from a high-dimensional space of raw data to a low-dimensional collection of actionable outcomes under the practical constraint of being computationally trackable. Without claiming of its optimality, the Continuous Piecewise Linear (CPL) functionals proposed by the artificial intelligence research community have demonstrated the ability of meeting all requirements listed previously through deep learning network architectures. The capability of analyzing high dimensional data has allowed deep learning to play an indispensable role in image processing and computer vision applications where the number of raw data is extremely high. In this talk, we will first briefly review the theoretical connection between deep learning architecture and Continuous Piecewise Linear functional. Afterwards, popular deep learning networks for classification, detection, segmentation, and generation will be summarized to give the audience an overall picture of deep learning architectures. At last, an outlook of the AI industry will be presented to show projected future growth opportunities and potential technical challenges.

BIOGRAPHY

Chunghui Kuo is the Editor-in-Chief at the Journal of Imaging Science and Technology and founder of Raycers Technology focusing on autonomous printing and intelligent environment sensing.

He received his PhD in Electrical and Computer Engineering from the University of Minnesota and joined Eastman Kodak Company in 2001. He was a senior scientist, a Distinguished Inventor, and served as an IP coordinator at the Eastman Kodak Company. He holds 52 US patents, where his patented automatic white-blending workflow received 2017 Canadian Printing Award. He had served as an industrial standardization committee member from 2005 to 2008 at the International Organization for Standardization (ISO).

He is a senior member of the IEEE Signal Processing Society and his research interests are in image processing, computer vision, blind signal separation and classification, and artificial intelligence applied in signal/image processing.

Professor

Hung-Yi Lee

National Taiwan University, Taiwan

How Far Are We from a Speech Version of ChatGPT?

Over the past few months, the capabilities of large language models like ChatGPT have drawn widespread discussion and amazement, but they only focus on text processing. How far are we from a speech-based ChatGPT? What are we missing that prevents the birth of a speech-based ChatGPT? In this presentation, I will share a series of the latest research findings that might lead us towards a speech-based ChatGPT and explore the current challenges and potential solutions.

BIOGRAPHY

Hung-Yi Lee is an associate professor of the Department of Electrical Engineering of National Taiwan University (NTU), with a joint appointment at the Department of Computer Science & Information Engineering of the university. His recent research focuses on developing technology that can reduce the requirement of annotated data for speech processing (including voice conversion and speech recognition) and natural language processing (including abstractive summarization and question answering). He won Salesforce Research Deep Learning Grant in 2019, AWS ML Research Award in 2020, Outstanding Young Engineer Award from The Chinese Institute of Electrical Engineering in 2018, Young Scholar Innovation Award from Foundation for the Advancement of Outstanding Scholarship in 2019, Ta-You Wu Memorial Award from Ministry of Science and Technology of Taiwan in 2019, and The 59th Ten Outstanding Young Person Award in Science and Technology Research & Development of Taiwan. He owns a YouTube channel teaching deep learning in Mandarin with about 100k Subscribers.

Analog Devices, Inc., Taiwan

Energy-Efficient Generative AI Future: Low-Power Applications of ADI Max78000

The ADI Max78000 is a powerful, low-power microcontroller with advanced features like the Arm Cortex-M4F processor and a robust neural network accelerator, enabling efficient execution of complex AI tasks. On the other hand, Generative AI, particularly Generative Adversarial Networks (GANs), can locally generate high-quality images, sounds, and text, adding rich interactivity and creativity to edge devices.

With its low-power characteristics, the ADI Max78000 is perfectly suited for edge devices where energy efficiency is crucial for prolonged operation without frequent recharging or replacing batteries. By carefully optimizing power consumption during AI model inference and leveraging the CNN accelerator, the Max78000 can achieve remarkable AI performance while conserving energy, making it an excellent choice for battery-powered and energy-sensitive applications.

Inconclusion, by harnessing the strengths of CNN acceleration and low-power characteristics, the integration of ADI Max78000 with Generative AI unlocks new possibilities for innovative and energy-efficient edge AI applications. Whether it's enhancing image synthesis, generating realistic content, or enabling interactive voice assistants, this powerful combination opens up endless opportunities to create intelligent and sustainable AI solutions for the future.

BIOGRAPHY

Currently, as a part of Analog Devices Inc. (ADI), a world-renowned semiconductor leader, I am thrilled to be a member of the dynamic team responsible for AI-related product research and development. Drawing upon my over 20 years of experience in semiconductor industry, I will bring a wealth of expertise in engineering and FAE roles.

ADI is renowned for its world-class analog, mixed-signal, and digital signal processing (DSP) technologies, which enable the development of a wide range of applications across various sectors. From healthcare and automotive to industrial, communications, and consumer electronics, ADI's products play a crucial role in shaping the future of these industries.

At ADI, we are committed to pushing the boundaries of AI technology and its applications across various industries. Leveraging my extensive background in programming software, firmware, and hardware circuit design, I am excited to contribute to the creation of cutting-edge AI solutions that cater to our customers' specific needs and drive technological advancements in the semiconductor field.

TUTORIAL SPEAKERS

09:30-17:30, October 31

[T01] Advancements in AI: Transformers, Media Forensics and Cybersecurity

Jun-Wei Hsieh

National Yang-Ming Chiao-Tung University, Taiwan

Jun-Wei Hsieh is a Professor with the College of AI, National Yang-Ming Chiao-Tung University. He was an Associate Professor with the Department of Electrical Engineering, Yuan-Ze University from August 1999 to July 2009, and a Visiting Researcher with the MIT AI Laboratory. Since August 2009, he had been a Professor and the Dean of the Department of Computer Engineering, National Taiwan Ocean University. He hosted or co-hosted a lot of large-scale AI projects from different companies and governments in the past. He has a lot of successful experiences in industrial-academic cooperation and technology transferring, especially in ITS. His research interests include AI, deep learning, smart farming, video surveillance, intelligent transportation systems, image and video processing, object recognition, machine learning, 3D printing, medical image analysis, and computer vision. In May 2019, he received the First Prize of the Ministry of Science and Technology Best Display Award and the Third Place of the AI Investment Potential Award. Due to his contributions in traffic flow estimation, he helped the Elan company receive the Gold Award from Taipei International Computer Show, in 2019. He also received the Outstanding Research Awards of National Taiwan Ocean University, in 2012, 2016, 2017, and 2019, the Outstanding Research Awards of Yuan Ze University, in 2006, 2007, 2008. He and his students received the Silver Medal of 2019 National College Software Creation Competition, the Silver Medal of 2018 National Microcomputer Competition, the Best Paper awards of Information Technology and Applications in Outlying Islands Conference, in 2013, 2014, 2016, 2017, 2018, 2021, 2022, and 2023, respectively, the Best Paper Award of Tanet 2017, the Best Paper Awards of NCWIA 2020, 2021, 2022, and 2023, respectively, and the Best Paper Awards of IS3C 2020. He also received the Best Paper Award of CVGIP Conference, in 1999, 2003, 2005, 2007, 2014, 2017, 2018, and 2023, the Best Paper Award of DMS Conference, in 2011, the Best Paper Award of IIHMSP 2010, and the Best Patent Award of Institute of Industrial Technology Research, in 2009 and 2010, respectively. Dr. Hsieh also received the award of 2022 future technology in Taiwan.

Ming-Ching Chang

University at Albany, State University of New York, USA

Dr. Ming-Ching Chang's research has been founded by DARPA, IARPA, NIJ, VA, and GE Global Research. He has rich experience in leveraging expertise from multiple domains to accomplish multi-discipline programs and projects. Dr. Chang receives multiple paper awards from international conferences including IEEE MIPR 2023 Best Student Paper Award, AI City Challenge 2017 Honorary Mention Award, IEEE WACV 2012 Best Student Paper Award, and IEEE AVSS 2011 Best Paper Award - Runner-Up. Dr. Chang frequently serves the program chair, area chair, and referee of leading journals and conferences. He is the core organizer of the AI City Challenge, a multi-year (2017-2023) IEEE CVPR Workshops. He is the program chair of the IEEE AVSS 2019 conference and TPC chair lead of the IEEE MIPR 2022 conference. He is the Area Chair of IEEE ICIP conferences (2017, 2019-2023) and an outstanding area chair of ICME 2021 conference. He chairs the steering committee of the IEEE AVSS conference since 2022. He has authored more than 130+ peer-reviewed journal and conference publications, 7 US patents and 15 disclosures. He is a senior member of IEEE.

[T02] Defending against Misinformation in the Wild

Chih-Chung Hsu

National Cheng Kung University, Taiwan

Chih-Chung Hsu is affiliated with the Institute of Data Science at National Cheng Kung University, located in Tainan, Taiwan (70101). You can contact him via email at cchsu@gs.ncku.edu.tw. Dr. Hsu obtained his Ph.D. degree in electrical engineering from National Tsing Hua University (NTHU) in Hsinchu, Taiwan, in 2014. He is a Senior Member of the Institute of Electrical and Electronics Engineers (IEEE) since October 2020. Dr. Hsu has made significant contributions to the field, publishing in several top-tier journals such as IEEE Transactions on Image Processing (TIP), IEEE Transactions on Multimedia (TMM), IEEE Transactions on Geoscience and Remote Sensing (TGRS), and IEEE Transactions on Pattern Analysis and Machine Intelligence (TPAMI). In 2017 and 2019, he received the first-place award in the ACM Multimedia Social Media Prediction Challenge. Additionally, in 2013, he was honored with a top 10% paper award at the IEEE International Workshop on Multimedia Signal Processing (MMSP). In 2019, Dr. Hsu received the best student paper award at the IEEE International Conference on Image Processing (ICIP). Furthermore, Dr. Hsu's achievements include winning the 3rd place award in the Learning to Drive Challenge at the IEEE International Conference on Computer Vision (ICCV) and being invited to give a talk in 2019. In 2020, he received the 3rd place award in the Visual Inductive Priors for Data-Efficient Computer Vision Challenge at the European Conference on Computer Vision (ECCV). Notably, he was recognized with the third place award in the COVID19 Detection Challenge at ICCV 2021 and the first place award at ECCV 2022. Dr. Hsu's research interests encompass image processing, deep learning, hyperspectral image analysis, and medical signal analysis.

Cheng-Te Li

National Cheng Kung University, Taiwan

Cheng-Te Li is now Professor at Institute of Data Science and Department of Statistics, National Cheng Kung University, Tainan, Taiwan. He received Ph.D. degree (2013) from Graduate Institute of Networking and Multimedia, National Taiwan University. Before joining NCKU, he was an Assistant Research Fellow (2014-2016) at Research Center for IT Innovation, Academia Sinica. Dr. Li's research targets Machine Learning, Deep Learning, and Data Science with their applications to Social Networks & Social Media Analytics, Recommender Systems, and Natural Language Processing. Problems he tackled are inspired by real-world applications with massive datasets, and methods his group present tend to be graph-based. His papers were published at top venues, including KDD, TheWebConf (WWW), ICDM, CIKM, SIGIR, IJCAI, ACL, EMNLP and NAACL. Dr. Li given keynote talks on graph neural networks for social media analytics at the MAISoN workshop at TheWebConf 2020 and at MISNC 2021. He had delivered conference tutorials on graph neural networks (TheWebConf 2023, IEEE ICDE 2023, IEEE DSAA 2022, and ACML 2021), and social media analytics (PAKDD 2016, WWW 2015, ICWSM 2014, and IEEE/ACM ASONAM 2014).

Jun-Cheng Chen

Aademia Sinica, Taiwan

Jun-Cheng Chen is an associate research fellow at the Research Center for Information Technology Innovation (CITI), Academia Sinica. He joined CITI as an assistant research fellow in 2019. He received the B.S. and M.S. degrees advised by Prof. Ja-Ling Wu in Computer Science and Information Engineering from National Taiwan University, Taiwan (R.O.C), in 2004 and 2006, respectively, where he received the Ph.D. degree advised by Prof. Rama Chellappa in Computer Science from University of Maryland, College Park, USA, in 2016. From 2017 to 2019, he was a postdoctoral research fellow at University of Maryland Institute for Advanced Computer Studies. His research interests include computer vision, machine learning, deep learning and their applications to biometrics, such as face recognition/facial analytics, activity recognition/detection in the visual surveillance domain, etc. He has published several papers on top conferences, including CVPR, ICCV, ECCV, ACM Multimedia. He was a recipient of the ACM Multimedia Best Technical Full Paper Award in 2006.

[T03] Deep learning beyond curve fitting - Understanding bias and fairness in Computer Vision in the era of DALL-E and ChatGPT

Arghya Pal

Monash University Malaysia, Malaysia

Dr. Arghya Pal is a Lecturer at the School of IT, Monash University. Dr. Pal has extensive research experiences in Computer Vision, Data Analytics, Large Language Modeling, Causality and Reasoning. Dr. Pal has got his academic studies from Harvard University, Monash University, and Indian Institute of Technology. He is a recipient of the Intel fellowship, magna-cum-laude merit award, and Gold Medal during his masters studies. Dr. Pal is a reviewer of prestigious journals like TPAMI, Pattern Recognition, Signal Processing Letters and conferences such as NeurIPS, CVPR, ICML, ICCV, ECCV, AAAI, ACL.

Sailaja Rajanala

Monash University Malaysia, Malaysia

Dr Sailaja obtained her Masters and PhD from the Indian Institute of Technology Hyderabad. Her research interests in Machine Learning, Natural Language Processing, and Causal Inference. In her PhD, she applied Machine learning to Natural Language Processing, Data Mining and Recommender Systems. She has published papers in several premier conferences including WACV, SIGIR, and ACM Multimedia. She had previously worked at Accenture Services pvt. ltd. as associate software engineer in data warehousing and data mining.

Ai-Fang Chai

Monash University Malaysia, Malaysia

DMs. Ai-Fang Chai is a Ph.D. student of School of IT, Monash University, Malaysia Campus. She has done extensive research in de-biasing, fairness in multimedia models. Ms. Ai Chai is also interested in micro expression detection and video generation models.

[T04] Advances in Psychoacoustics and Machine Learning towards Objective Speech Intelligibility Evaluation

Fei Chen

Southern University of Science and Technology (SUSTech), China

Fei Chen received the B.Sc. and M.Phil. degrees from the Department of Electronic Science and Engineering, Nanjing University in 1998 and 2001, respectively, and the Ph.D. degree from the Department of Electronic Engineering, The Chinese University of Hong Kong in 2005. He continued his research as post-doctor and senior research fellow in University of Texas at Dallas (supervised by Prof. Philipos C. Loizou) and The University of Hong Kong. He is now a full professor at Department of Electrical and Electronic Engineering, Southern University of Science and Technology (SUSTech), Shenzhen, China. Dr. Chen is leading the speech and physiological signal processing (SPSP) research group in SUSTech, with research focus on speech perception, speech intelligibility modeling, speech enhancement, and assistive hearing technology. He published over 140 journal papers and over 100 conference papers in IEEE journals/conferences, Interspeech, Journal of Acoustical Society of America, etc. He was tutorial speakers of Interspeech 2022, EUSIPCO2022, APSIPA 2021, Interspeech 2020, and APSIPA 2019, and organized special session "Signal processing for assistive hearing devices" at ICASSP 2015. He received the best presentation award in the 9th Asia Pacific Conference of Speech, Language and Hearing. Dr. Chen is an APSIPA distinguished lecturer (2022-2023), and is now serving as associate editor of Biomedical Signal Processing and Control.

Yu Tsao

Academia Sinica, Taiwan

Yu Tsao received the B.S. and M.S. degrees in electrical engineering from National Taiwan University, Taipei, Taiwan, in 1999 and 2001, respectively, and the Ph.D. degree in electrical and computer engineering from the Georgia Institute of Technology, Atlanta, GA, USA, in 2008. From 2009 to 2011, he was a Researcher with the National Institute of Information and Communications Technology, Tokyo, Japan, where he engaged in research and product development in automatic speech recognition for multilingual speech-to-speech translation. He is currently a Research Fellow (Professor) and the Deputy Director with the Research Center for Information Technology Innovation, Academia Sinica, Taipei, Taiwan. He is also a Jointly Appointed Professor with the Department of Electrical Engineering, Chung Yuan Christian University, Taoyuan, Taiwan. His research interests include assistive oral communication technologies, audio coding, and bio-signal processing. He is currently an Associate Editor for the IEEE/ACM TRANSACTIONS ON AUDIO, SPEECH, AND LANGUAGE PROCESSING and IEEE SIGNAL PROCESSING LETTERS. He was the recipient of the Academia Sinica Career Development Award in 2017, national innovation awards in 2018– 2021, Future Tech Breakthrough Award 2019, and Outstanding Elite Award, Chung Hwa Rotary Educational Foundation 2019–2020. He is the corresponding author of a paper that received the 2021 IEEE Signal Processing Society (SPS), Young Author, Best Paper Award.

[T05] Spoofing Face Recognition Systems with Adversarial Examples: Challenges and Countermeasures

Mehul S Raval

Ahmedabad University, India

Dr. Mehul S Raval is a faculty member at Ahmedabad University, serving as the Associate Dean of Experiential Learning and Professor. He has over 25 years of experience in computer vision and engineering education. In 1996, Mehul earned his Bachelor's in Electronics and Telecommunication Engineering from the College of Engineering Pune / University of Pune, India. He pursued further studies, obtaining a Master's in Electronics in 2002 and a Ph.D. in ECE in 2008.

Dr. Raval has had the opportunity to engage in academic activities abroad, conducting research at Okayama University in Japan as a recipient of the Sakura Science fellowship. He also served as an Argosy visiting associate professor at Olin College of Engineering in the United States in 2016 and held a visiting professorship at Sacred Heart University, CT, in 2019.

Dr. Raval's research has been published in reputable journals, magazines, conferences, and workshops. He has been a reviewer for well-known publishers, including IEEE, ACM, Springer, Elsevier, IET, and SPIE. His research has received support from institutions such as the Board of Research in Nuclear Science (BRNS) and the Department of Science and Technology, Government of India.

Dr. Raval mentors doctoral, M.Tech, and B.Tech students and actively contributes to conferences, workshops, and symposiums as a program committee member. He also participates in curriculum development for esteemed Indian universities as a Board of Studies (BoS) member. Dr. Raval holds senior memberships in IEEE and prestigious titles as a Fellow of IETE and Fellow of The Institution of Engineers (India). He has contributed to the IEEE Gujarat section and served in various capacities within the IEEE Signal Processing Society (SPS) chapter - IEEE Gujarat Section and the IEEE Computational Intelligence Society Chapter - IEEE Gujarat Section.

Minoru Kuribayashi

Tohoku University, Japan

Minoru Kuribayashi received B.E., M.E., and D.E degrees from Kobe University, Japan, in 1999, 2001, and 2004. He was a Research Associate and an Assistant Professor at Kobe University from 2002 to 2007 and 2007 to 2015, respectively. Since 2015, he has been an Associate Professor at the Graduate School of Natural Science and Technology, Okayama University. His research interests include multimedia security, digital watermarking, cryptography, and coding theory. He is an associate editor of IEEE Signal Processing Letters, JISA and IEICE. He is a chair of APSIPA TC of Multimedia Security and Forensics and a TC member of IEEE SPS Information Forensics and Security. He received the Young Professionals Award from IEEE Kansai Section in 2014 and the Best Paper Award from IWDW 2015 and 2019. He is a senior member of IEEE and IEICE.

Mohendra Roy

Pandit Deendayal Energy University, India

Dr. Mohendra Roy is an expert in the area of Artificial Intelligence and experienced in developing biomedical sensors / devices. He is currently serving as an assistant professor at the school of technology of Pandit Deendayal Energy University (PDEU), India. He was a post doctoral fellow at Delta-NTU Corporate Lab of Nanyang Technological University, Singapore. He received his Ph.D. in Electronics and Information Engineering from Korea University, South Korea. He did his master's in Bio-Electronics as well as Physics from Tezpur Central University, India.

He received the Korea University achievement award, IEEE student paper award by IEEE Seoul section, outstanding paper award from the Korean BioChip Society, award at India International Science Festival 2020 by the Ministry of Science and Technology, Government of India, and Gold Medal from Tezpur University. He has published several high-quality research papers in IEEE transactions, Journal of Machine Learnng: S & T, Biosensors & Bioelectronics Journal, Sensors and Actuators B, etc.

WOMEN'S FORUM SPEAKERS

12:00-13:30, November 2

Moderator

Bonnie N.F. Law

The Hong Kong Polytechnic University

Dr. Bonnie N.F. Law received the BEng (Hons) degree with first-class honors from the University of Auckland, New Zealand, in 1993 and the Ph.D. degree from the University of Tasmania, Australia, in 1997. She is currently an associate professor in the Department of Electrical and Electronic, the Hong Kong Polytechnic University. Her research interests include signal and image processing, and machine learning. Recently, she has extended her study into various new applications, such as information security and bioinformatics. The former includes source camera identification and network traffic anomaly detection, while the latter involves gene expression and DNA sequence analysis. She has served as a committee member for many IEEE/APSIPA conferences, the technical committee member of APSIPA TC on Multimedia Security and Forensics.

Speaker

Chiori Hori

Mitsubishi Electric Research Laboratories (MERL), USA

Dr. Chiori Hori is a Senior Principal Research Scientist at Mitsubishi Electric Research Laboratories (MERL) in Cambridge, MA, where she has worked since 2015. Her research is focused on multimodal scene-aware interaction technologies for human-robot communications. Prior to MERL, she spent eight years at the National Institute of Information and Communication Technology (NICT) in Japan, and before that she was a researcher at Carnegie Mellon University (CMU) and NTT Communication Science Laboratories. At NICT, she was the director of the Spoken Language Communication Laboratory, where she led multiple projects in network-based speech translation systems for the international consortium U-STAR. Dr. Hori has received several awards, including the 24th TELECOM System Technology Award in 2009, the International Cooperation Award from ITU-AJ in 2012, the DOCOMO Mobile Science Award for Social Science Sector in 2012, and the 58th Maejima Hisoka Award in 2013. She served on the editorial board of the journal Computer Speech and Language, and she was a technical committee member of the Speech and Language Processing Group of the IEEE Signal Processing Society. She received her Ph.D. degree from the Tokyo Institute of Technology.

12:00-13:30, November 2

Speaker

Cynthia Chen

University of Washington, USA

Cynthia Chen is a professor in the Department of Civil & Environmental Engineering at the University of Washington (Seattle). She is also a professor and the interim chair of the Department of Industrial & Systems Engineering at UW. She is an internationally renowned scholar in transportation science and directs the THINK (Transportation-Human Interaction and Network Knowledge) lab at the UW. Cynthia has published over 60 peer-reviewed publications in leading journals in transportation and systems engineering including Transportation Research Part A-F and Omega, as well as interdisciplinary journals such as PNAS. Her research has been supported by federal agencies such as NSF, NIH, APAR-E, NIST, USDOT, and FHWA as well as state and regional agencies. Cynthia served a two-year assignment (2017-19) as the Program Director of Civil Infrastructure Systems, CMMI (Civil, Mechanical, and Manufacturing Innovation) division with the National Science Foundation. She is an associate director of TOMNET (Center for Teaching Old Models New Tricks), a USDOT-funded Tier 1 University Transportation Center led by ASU, as well as a key member of the new Center of Understanding Future Travel Behavior and Demand, a USDOT-funded national center led by UT Austin. Currently, Cynthia serves as an associate editor for Transportation Science, and is on the editorial board of Sustainability Analytics and Modeling.

Speaker

Simying Ong

Universiti Malaya, Malaysia

Simying Ong is currently the Head of Department and a Senior Lecturer at the Faculty of Computer Science and Information Technology, Universiti Malaya, Malaysia. She was awarded with Bachelor Degree of Computer Science (Software Engineering) and Doctor of Philosophy (Information Security) in 2009 and 2015 by Universiti Malaya, Malaysia. Her research interests include image/signal processing and its related applications, information security (perceptual lightweight encryption and data hiding), and multimedia security usability.

She is actively involved in the reviewing activities in various conferences and journals including IEEE ICME, IEEE ICASSP, IEEE TCSVT, Elsevier JVCI. She was also awarded the Certificate of Excellence Service (by Universiti Malaya) 2022, IEEE SPS Malaysia Research Excellence Award 2021 - Best Conference Paper Award, IEEE ICME Outstanding Reviewers Award 2020-2021, etc.

12:00-13:30, November 2

Speaker

Pei-Yun Tsai

National Central University, Taiwan

Pei-Yun Tsai received the B.S., M.S., and Ph.D. degrees in electrical engineering from the National Taiwan University, Taipei, Taiwan. She is currently a Professor of Electrical Engineering at the National Central University, Taoyuan, Taiwan. Her research interests include digital signal processing algorithms and VLSI design for wireless communication systems, radar systems, and biomedical systems.

Prof. Tsai was a member of the Design and Implementation of Signal Processing Systems (DISP) Technical Committee of the IEEE Signal Processing Society from 2015 to 2020, and in 2021, she was also a member of the Applied Signal Processing Systems (ASPS) Technical Committee of the IEEE Signal Processing Society. Since 2019, she has been a member of the Circuits and Systems for Communications (CASCOM) Technical Committee of the IEEE Circuits and Systems Society. She has been technical committee member of Signal Processing Systems in Asia-Pacific Signal and Information Processing Association (APSIPA) from 2014. She received Future Tech Award and National Innovation Award in 2022.

November 1 (Wednesday) 10:20-12:00

A1 Biomedical Signal Processing and Systems — 101AB

Chair: Kiyoshi Nishikawa (Tokyo Metropolitan University, Japan)

A1-1 10:20

Mixed Emotion Recognition Based on EEG Signals

Guanxiong Pei (Zhejiang Lab, China); Bingjie Li (National University of Singapore, China); Taihao Li (Zhejiang Lab, China); Cunhang Fan, Chao Zhang and Zhao Lv (Anhui University, China)

A1-2 10:40

Attention-Based CNN and Relative Phase Feature Modeling for Improved Imagined Speech Recognition

Yoshiki Niimura, Jun Takemoto and Atsuhiko Kai (Shizuoka University, Japan); Seiichi Nakagawa (Chubu University, Japan)

A1-3 11:00

Manipulation of Neuronal Network Firing Patterns Using Temporal Deep Unfolding-Based MPC

Jumpei Aizawa and Masaki Ogura (Osaka University, Japan); Masanori Shimono (Kyoto University, Japan); Naoki Wakamiya (Osaka University, Japan)

A1-4 11:20

Goodness of Fit to the Convolution Model of fMRI Data and Determination of the Regularization Parameter

Wakako Nakamura (Shimane University, Japan)

A1-5 11:40

Detection Model of Sister Chromatid Cohesion Defects Based on Vision Transformer

Shinya Matsumoto, Kan Okubo, Kiyoshi Nishikawa and Takuya Abe (Tokyo Metropolitan University, Japan)

B1 Data Analytics and Machine Learning — 101C

Chair: Zixiang Xiong (Texas A&M University, USA) / Heri Prasetyo (Universitas Sebelas Maret, Indonesia)

B1-1 10:20

GRALA: Modeling Social Information for Microblog Sentiment Analysis from the View of Balancing Sparsity and Smoothness of Social Contexts

Xiaomei Zou (Zhejiang Lab, China); Shiyong Hu (Hangzhou Applied Acoustics Research Institute, China); Taihao Li (Zhejiang Lab, China)

B1-2 10:40

Adopting Neural Translation Model in Data Generation for Inverse Text Normalization

Yufei Jiang, Thi-Nga Ho and Eng-Siong Chng (Nanyang Technological University, Singapore)

November 1 (Wednesday) 10:20-12:00

B1 Data Analytics and Machine Learning 101C

Chair: Zixiang Xiong (Texas A&M University, USA) / Heri Prasetyo (Universitas Sebelas Maret, Indonesia)

B1-3 11:00

Mismatched Semi-Supervised Learning with Feature Similarity Consistency

Zechen Liang and Yuan-Gen Wang (Guangzhou University, China)

B1-4 11:20

Collaborative Pseudo Labeling for Prompt-Based Learning

Jen-Tzung Chien and Chien-Ching Chen (National Yang Ming Chiao Tung University, Taiwan)

B1-5 11:40

Learning Meta Soft Prompt for Few-Shot Language Models

Jen-Tzung Chien and Ming-Yen Chen (National Yang Ming Chiao Tung University, Taiwan); Jing-Hao Xue (University College London, United Kingdom (Great Britain))

C1 Deep Learning: Algorithm, Implementations, and Applications 101D

Chair: Yao-Chung Chang (National Taitung University, Taiwan) / Woon-Seng Gan (Nanyang Technological University, Singapore)

C1-1 10:20

MSDF-Net: A Multi-Scale Deep Fusion Network with Dilated Convolutions for Cloud Removal from Sentinel-2 Imagery

Jayakrishnan A and Venkatesan M (National Institute of Technology Puducherry, India); Prabhavathy Panneer (VIT University, India); Alkha Mohan (Indian Institute of Information Technology Tiruchirappalli, India)

C1-2 10:40

Instance Implant-Aided Non-Uniformly Cropping for Person Detection in Aerial Images

Xiangqing Zhang (Northwestern Polytechnical University & Yan'an University, China); Yan Feng (Northwestern Polytechnical University, China)

C1-3 11:00

A Futuristic Proposed Solution to a Global Challenge: The Promise of AI for Social Distancing Compliance

Yi Pei Ng, Chi Wee Tan, Ts. and Yiqi Tew (Tunku Abdul Rahman University of Management and Technology, Malaysia)

C1-4 11:20

Unbiased Decision-Making Framework in Long-Video Macro & Micro-Expression Spotting

Pei Sze Tan, Sailaja Rajanala, Arghya Pal, Raphael C.-W. Phan and Huey Fang Ong (Monash University Malaysia, Malaysia)

November 1 (Wednesday) 10:20-12:00

D1 Recent Advances on Speech Preprocessing in Multi-Speaker Scenarios 102

Chair: Jun Du (University of Science and Technology of China, China) / Yu Tsao (Academia Sinica, Taiwan)

D1-1 10:20

Adaptive Beamforming Based on Interference-Plus-Noise Covariance Matrix Reconstruction for Speech Separation

Yongxiong Xiao, Shiqiang Zhu, Te Li, Minhong Wan and Wei Song (Zhejiang Lab, China); Jason Gu (Dalhousie University, Canada); Qiang Fu (Zhejiang Lab, China)

D1-2 10:40

Correlated Multi-Level Speech Enhancement for Robust Real-World ASR Applications Using Mask-Waveform-Feature Optimization

Hang Chen, Jun Du, Zhe Wang and Chenxi Wang (University of Science and Technology of China, China); Yuling Ren, Qinglong Li and Ruibo Liu (China Mobile Online Services Company Limited, China); Chin-Hui Lee (Georgia Institute of Technology, USA)

D1-3 11:00

CASA-Net: Cross-Attention and Self-Attention for End-To-End Audio-Visual Speaker Diarization

Haodong Zhou, Tao Li, Jie Wang, Li Lin and Qingyang Hong (Xiamen University, China)

D1-4 11:20

Enhanced Neural Beamformer with Spatial Information for Target Speech Extraction

Aoqi Guo (Ocean University of China, China); Junnan Wu, Peng Gao and Wenbo Zhu (Xiaomi Corporation, China); Qinwen Guo and Gao Da Zhi (Ocean University of China, China); Yujun Wang (Xiaomi Corporation, China)

D1-5 11:40

Low-Complexity Multi-Channel Speaker Extraction with Pure Speech Cues

Bang Zeng (Wuhan University & Duke Kunshan University, China); Hongbin Suo and Yulong Wan (OPPO, China); Ming Li (Duke Kunshan University, China)

November 1 (Wednesday) 10:20-12:00

E1 SLA-I: Speaker Recognition and Spoken Language Identification 201A

Chair: Man-Wai Mak (The Hong Kong Polytechnic University, Hong Kong)

E1-1 10:20

Modeling Suprasegmental Information Using Finite Difference Network for End-To-End Speaker Verification

Jin Li and Man Wai Mak (The Hong Kong Polytechnic University, Hong Kong); Nan Yan and Lan Wang (Shenzhen Institutes of Advanced Technology, Chinese Academy of Sciences, China)

E1-2 10:40

Relevance of Quadrature Phase for Replay Detection in Voice Assistants (VAs)

Priyanka Gupta, Piyushkumar K. Chodingala and Hemant A. Patil (Dhirubhai Ambani Institute of Information and Communication Technology, India)

E1-3 11:00

Exploring Residual Cepstral Features for Spoken Language Identification

Baveet Singh Hora, Krishna Parmar, Shrey Machhar and Hemant A. Patil (Dhirubhai Ambani Institute of Information and Communication Technology, India); Kiran Praveen and Balaji Radhakrishnan (Samsung Research Institute, Bangalore, India)

E1-4 11:20

Consideration of Varying Training Lengths for Short-Duration Speaker Verification

WooSeok Ko, Seyun Um, Zhenyu Piao and Hong-Goo Kang (Yonsei University, Korea)

E1-5 11:40

Adversarial Robustness of Mel Based Speaker Recognition Systems

Ritu Srivastava, Saiteja Kosgi, Sarath Sivaprasad Neha Sahipjohn and Vineet Gandhi (IIIT Hyderabad, India)

F1 SLA-II: Music Information Processing 201B

Chair: Hideki Kawahara (Wakayama University, Japan)

F1-1 10:20

Joint Drum Transcription and Metrical Analysis Based on Periodicity-Aware Multi-Task Learning

Daichi Kamakura and Eita Nakamura (Kyoto University, Japan); Kazuyoshi Yoshii (Kyoto University & RIKEN, Japan); Takehisa Oyama (Kyoto University, Japan)

F1-2 10:40

CTC2: End-To-End Drum Transcription Based on Connectionist Temporal Classification with Constant Tempo Constraint

Daichi Kamakura and Eita Nakamura (Kyoto University, Japan); Kazuyoshi Yoshii (Kyoto University & RIKEN, Japan)

November 1 (Wednesday) 10:20-12:00

F1 SLA-II: Music Information Processing 201B

Chair: Hideki Kawahara (Wakayama University, Japan)

F1-3 11:00

Learning Multifaceted Self-Similarity for Musical Structure Analysis

Tsung-Ping Chen (Kyoto University, Japan); Li Su (Academia Sinica, Taiwan); Kazuyoshi Yoshii (Kyoto University & RIKEN, Japan)

F1-4 11:20

Simultaneous Measurement of Multiple Acoustic Attributes Using Structured Periodic Test Signals Including Music and Other Sound Materials

Hideki Kawahara (Wakayama University, Japan); Kohei Yatabe (Tokyo University of Agriculture and Technology, Japan); Ken-Ichi Sakakibara (Health Sciences University of Hokkaido, Japan); Mitsunori Mizumachi (Kyushu Institute of Technology, Japan); Tatsuya Kitamura (Konan University, Japan)

G1 Advanced Biomedical Signal Processing (I): Human Well-Being 201C

Chair: Yumie Ono (Meiji University, Japan)

G1-1 10:20

Cognitive Assessment of Autism Spectrum Disorder Using an EEG-Based Social Interaction Platform

Yi-Li Tseng (National Sun Yat-sen University, Taiwan)

G1-2 10:40

Gait Analysis in Powered Exoskeleton-Assisted Walking in Patients with Stroke: A Case Series Cohort

Jian-Jia Huang and Shih-Chieh Chang (Chang Gung Memorial Hospital, Taiwan); Cheng-Hsu Cheng (Chang Gung University, Taiwan); Timothy Wan (The University of Texas at Austin, Taiwan); Yu-Cheng Pei (Chang Gung Memorial Hospital, Taiwan)

G1-3 11:00

Prediction Model of Postoperative Pain Exacerbation Using a Wearable Electrocardiogram Sensor

Toshiyuki Nakanishi (Nagoya City University & Nagoya University, Japan); Koichi Fujiwara (Nagoya University, Japan); Kazuya Sobue (Nagoya City University, Japan)

G1-4 11:20

Directional Neural Connectivity During Robot Mirror Therapy in Patients with Stroke

Yuma Kanaizuka and Takahiro Manabe (Meiji University, Japan); Jian-Jia Huang (Chang Gung Memorial Hospital, Taiwan); Jen-Wen Hung (Chang Gung Memorial Hospital-Kaohsiung Medical Center/Chang Gung University, Taiwan); Yumie Ono (Meiji University, Japan)

November 1 (Wednesday) 10:20-12:00

G1 Advanced Biomedical Signal Processing (I): Human Well-Being 201C

Chair: Yumie Ono (Meiji University, Japan)

G1-5 11:40

Evaluation of Neural Response Recorded Using Scalp EEG in Virtual Reality Environment

Noriaki Kanayama (AIST, Japan); Makoto Miyakoshi (Swartz Center for Neural Computation, Institute for Neural Computation, University of California San Diego); Maro G Machizawa (Hiroshima University, Japan & Xiberlinc Inc., Japan)

H1 Advanced Information Processing Technologies for Human and World 201D

Chair: Te-Chuan Chiu (National Tsing Hua University, Taiwan)

H1-1 10:20

Machine Learning Based Action Recognition with Modular CNN

Shi-Zong Huang, Ching-Te Chiu and Yu-Jen Chang (National Tsing Hua University, Taiwan)

H1-2 10:40

Real-Time Processing for Weighted Pulse Decomposition of Photoplethysmography Signals Based on Interior Point Method in Wearable Devices for Hemodynamic State

Ting-Jui Wong and Pei-Yun Tsai (National Central University, Taiwan)

H1-3 11:00

QoS-Aware Downlink Beamforming for Joint Transmission in Multi-Cell Networks

Chen-Yen Lin (MediaTek Inc., Taiwan); Kuang-Hao (Stanley) Liu (National Tsing Hua University, Taiwan)

H1-4 11:20

Deep-Learning-Based Lattice Reduction Preprocessing for Time-Correlated MIMO Systems

Yi-Mei Li, Jung-Chun Chi and Yuan-Hao Huang (National Tsing Hua University, Taiwan)

H1-5 11:40

Utilizing Unlabeled Data and Synthetic Data for Bird Sound Detection: Consistency Training, Mean Teacher, and Domain Adaptation Techniques

Fang-Ching Chen and Yi-Wen Liu (National Tsing Hua University, Taiwan)

November 1 (Wednesday) 10:20-12:00

I1 Selected Papers from APSIPA Workshop in Bandung, Indonesia (I) 201E

Chair: Trio Adiono (Institut Teknologi Bandung, Indonesia)

I1-1 10:20

A Comparative Evaluation of Video Codecs for rPPG-Based Heart Rate Estimation

Muhammad Heronan Hyanda (Institut Teknologi Bandung, Indonesia); Nur Ahmadi (Bandung Institute of Technology, Indonesia); Peter H Charlton (University of Cambridge & Guy's and St Thomas' NHS Foundation Trust, United Kingdom (Great Britain)); Timothy Constandinou (Imperial College London & Mint Neurotechnologies Ltd, United Kingdom (Great Britain)); Ayu Purwarianti (Bandung Institute of Technology, Indonesia); Trio Adiono (STEI ITB, Indonesia)

I1-2 10:40

Human Activity Recognition Based on FMCW Radar Using CNN and Transfer Learning

Listi R Triani and Nur Ahmadi (Bandung Institute of Technology, Indonesia); Trio Adiono (STEI ITB, Indonesia)

I1-3 11:00

DQN Algorithm Design for Fast Efficient Shortest Path System

A Sumarudin (Institut Teknologi Bandung, Indonesia & Politeknik Negeri Indramayu, Indonesia); Nana Sutisna (Institut Teknologi Bandung, Indonesia); Infall Syafalni (Bandung Institute of Technology, Indonesia); Trio Adiono (Institut Teknologi Bandung, Indonesia)

I1-4 11:20

Comparison of MPPT Based on Deep Reinforcement Learning by DQN, DDPG and TD3

Jayandi S Panggabean (Institut Teknologi Bandung & Calvin Institute of Technology, Indonesia); Trio Adiono and Nana Sutisna (Institut Teknologi Bandung, Indonesia); Infall Syafalni (Bandung Institute of Technology, Indonesia)

I1-5 11:40

Signal Quality Assessment for Wearable Multichannel Photoplethysmography Signals

Muhammad Dzaky Prihatmoko and Nur Ahmadi (Bandung Institute of Technology, Indonesia); Peter H Charlton (University of Cambridge & Guy's and St Thomas' NHS Foundation Trust, United Kingdom (Great Britain)); Trio Adiono (STEI ITB, Indonesia)

November 1 (Wednesday) 10:20-12:00

J1 Selected Papers from APSIPA Workshop in Hanoi, Vietnam (I) 201F

Chair: Nguyen Linh Trung (Vietnam National University, Hanoi, Vietnam)

J1-1 10:20

After-Fatigue Condition: A Novel Analysis Based on Surface EMG Signals

Hieu Van Nguyen (Phenikaa University, Vietnam); Thien Gia Luu (HUTECH University, Vietnam); Thien Van Luong and Trang Xuan Mai (Phenikaa University, Vietnam); Philippe Ravier and Olivier Buttelli (Université d'Orléans, France)

J1-2 10:40

On the Semi-Blind Mutually Referenced Equalizers for MIMO Systems

Do Hai Son (VNU University of Engineering and Technology, Vietnam); Karim Abed-Meraim (University of Orleans & PRISME Lab., France); Duy Trong Tran (VNU University of Engineering and Technology, Vietnam); Nguyen Linh Trung (Vietnam National University, Hanoi, Vietnam); Tran Thi Thuy Quynh (VNU University of Engineering and Technology, Vietnam)

J1-3 11:00

Accurate Continuous Action and Gesture Recognition Method Based on Skeleton and Sliding Windows Techniques

Viet-Duc Le (Hanoi University of Science and Technology, Vietnam); Thi-Lich Nghiem (Thuongmai University, Vietnam); Thi-Lan Le (School of Electrical and Electronic Engineering, HUST, Vietnam)

J1-4 11:20

Transformer-Based Deep Learning Detector for Dual-Mode Index Modulation 3D-OFDM

Toan Gian and Nguyen Tien Hoa (Hanoi University of Science and Technology, Vietnam); Thien Van Luong (Phenikaa University, Vietnam); Trungtan Nguyen (Le Quy Don Technical University, Vietnam); Van-Cuong Pham (Phenikaa University, Vietnam)

J1-5 11:40

GAFormer: Wearable IMU-Based Human Activity Recognition with Gramian Angular Field and Transformer

Nguyen Thai Khanh (Hanoi University of Science and Technology, Viet Nam); Trung-Hieu Le (Dai Nam University, Vietnam); Trung-Kien Tran (Institute of Information Technology, AMST, Vietnam); Thanh-Hai Tran (Hanoi University of Science and Technology, Vietnam); Cuong Pham (Posts & Telecommunications Institute of Technology, Vietnam)

November 1 (Wednesday) 15:00-17:00

A2 IVM-1: Multimedia Content Analysis and Assessment 101AB

Chair: Sanghoon Lee (Yonsei University, Korea) / Michiharu Niimi (Kyushu Institute of Technology, Japan)

A2-1 15:00

CH-MEAD: A Chinese Multimodal Conversational Emotion Analysis Dataset with Fine-Grained Emotion Taxonomy

Yu-Ping Ruan and Taihao Li (Zhejiang Lab, China)

A2-2 15:20

Evolutionary Analysis and Cultural Transmission Models of Color Style Distributions in Painting Arts

Eita Nakamura (Kyoto University, Japan); Yasuyuki Saito (National Institute of Technology, Kisarazu College, Japan)

A2-3 15:40

Ultimatelink Between Characters Having a Certain Meaning in Physical Space to URL in Cyberspace with Robust Print and Scan

Keiji Yamadera and Michiharu Niimi (Kyushu Institute of Technology, Japan)

A2-4 16:00

Human Flow Measurement System Using Floor Estimation of Depth Images for Low-End IoT Devices

Takuya Nagatoshi and Michiharu Niimi (Kyushu Institute of Technology, Japan)

A2-5 16:20

Holo-QoI: A Human Factor-Based Dataset and Prediction Framework for Assessing Quality of Interaction in Augmented Reality

Seongjean Kim, Seonghwa Choi and Sanghoon Lee (Yonsei University, Korea)

B2 Advanced Biomedical Signal Processing (II): Brain Signal Processing and Analysis 101C

Chair: Yumie Ono (Meiji University, Japan)

B2-1 15:00

Supervised Single-Channel EEG Decomposition Using Detector-Kernel Networks for Noise Reduction

Hiroshi Higashi (Osaka University, Japan)

November 1 (Wednesday) 15:00-17:00

B2 Advanced Biomedical Signal Processing (II): Brain Signal Processing and Analysis — 101C

Chair: Yumie Ono (Meiji University, Japan)

B2-2 15:20

Cross-Subject Classification of Spoken Mandarin Vowels and Tones with EEG Signals: A Study of End-To-End CNN with Fine-Tuning

Xinyu Wang, Mingtao Li and Hao Li (Southern University of Science and Technology, China); Sio Hang Pun (University of Macao, Macao); Fei Chen (Southern University of Science and Technology, China)

B2-3 15:40

Decoding Time-Course of Saliency Network of fMRI Signals by EEG Signals Using Optimized Forward Variable Selection: A Concurrent EEG-fMRI Study

Tung Dang, Kentaro Ono, Takafumi Sasaoka and Shigeto Yamawaki (Hiroshima University, Japan); Maro G Machizawa (Hiroshima University, Japan & Xiberlinc Inc., Japan)

B2-4 16:00

Multimodal Recognition of Speech and Electrocorticogram

Mitali Ahuja (Tokyo Institute of Technology, Japan); Shuji Komeiji (Tokyo University of Agriculture and Technology, Japan); Takumi Mitsuhashi (Juntendo University School of Medicine, Japan); Yasushi Iimura (Juntendo University, Japan); Hiroharu Suzuki (Juntendo University School of Medicine, Japan); Hidenori Sugano (Juntendo University, Japan); Koichi Shinoda (Tokyo Institute of Technology, Japan); Toshihisa Tanaka (Tokyo University of Agriculture and Technology, Japan)

C2 Multimedia Security and Privacy in the Age of Deep Learning — 101D

Chair: Maung Maung April Pyone (National Institute of Informatics, Japan)

C2-1 15:00

A Reversible Image Processing Method for Color Tone Control Using Data Hiding

Daichi Nakaya (University of Chiba, Japan); Shoko Imaizumi (Chiba University, Japan)

C2-2 15:20

Image-Text Out-Of-Context Detection Using Synthetic Multimodal Misinformation

Fatma Feak Mohamed Mohamed Shalabi (The Graduate University for Advanced Studies, SOKENDAI & National Institute of Informatics, Japan); Huy H. Nguyen (National Institute of Informatics, Japan); Hichem Felouat (The Graduate University for Advanced Studies, SOKENDAI, Japan); Ching-Chun Chang (National Institute of Informatics, Japan); Isao Echizen (National Institute of Informatics, Japan)

November 1 (Wednesday) 15:00-17:00

C2 Multimedia Security and Privacy in the Age of Deep Learning 101D

Chair: Maung Maung April Pyone (National Institute of Informatics, Japan)

C2-3 15:40

Gait Recognition Scheme Focusing on Operating Characteristics at Feature Points Detected by OpenPose

Chinatsu Tanaka (Okayama University, Japan); Minoru Kuribayashi (Tohoku University, Japan); Nobuo Funabiki (Okayama University, Japan)

C2-4 16:00

A Study on Eliminating Biased Node in Federated Learning

Reon Akai (Okayama University, Japan); Minoru Kuribayashi (Tohoku University, Japan); Nobuo Funabiki (Okayama University, Japan)

C2-5 16:20

Can StArtGAN Withstand Image Processing Attacks?

Ng Koi Yee and Simying Ong (University of Malaya, Malaysia); Yuen Peng Loh (Multimedia University, Malaysia)

C2-6 16:40

Enhancing Privacy Preservation with Quantum Computing for Word-Level Audio-Visual Speech Recognition

Chang Wang, Jun Du, Hang Chen and Ruoyu Wang (University of Science and Technology of China, China); Chao-Han Huck Yang (Georgia Institute of Technology, USA); Jiangjiang Zhao, Yuling Ren and Qinglong Li (China Mobile Online Services Company Limited, China); Chin-Hui Lee (Georgia Institute of Technology, USA)

D2 The Intersection of AI and Computer Vision: Advancements and Opportunities 102

Chair: Yuen Peng Loh (Multimedia University, Malaysia) / Sue-Han Lee (Swinburne University of Technology, Malaysia)

D2-1 15:00

Interpretable Image Recognition in Hyperbolic Space

Irina Lebedeva, Mohamed Jaward Bah and Taihao Li (Zhejiang Lab, China)

D2-2 15:20

Low-Light is More than Darkness: An Empirical Study on Illumination Types and Enhancement Methods

Hui Sze Liew (Universiti Malaya, Malaysia); Yuen Peng Loh (Multimedia University, Malaysia); Simying Ong (University of Malaya, Malaysia)

November 1 (Wednesday) 15:00-17:00

D2 The Intersection of AI and Computer Vision: Advancements and Opportunities 102

Chair: Yuen Peng Loh (Multimedia University, Malaysia) / Sue-Han Lee (Swinburne University of Technology, Malaysia)

D2-3 15:40

MoMo Strategy: Learn More from More Mistakes

Sophia Chulif (Swinburne University of Technology Sarawak Campus, Malaysia); Sue Han Lee (Swinburne University of Technology, Malaysia); Yang Loong Chang (Neuon AI Sdn. Bhd., Malaysia); Mark Tee Kit Tsun (Swinburne University of Technology, Malaysia); Kok Chin Chai (UNIMAS, Malaysia); Yi Lung Then (Universiti Malaysia Sarawak, Malaysia)

D2-4 16:00

Unveiling Robust Feature Spaces: Image vs. Embedding-Oriented Approaches for Plant Disease Identification

Sue Han Lee, Hamza Ahmed Ishrat and Abel Yu Hao Chai (Swinburne University of Technology, Malaysia); Patrick Then (Swinburne University of Technology Sarawak Campus, Malaysia)

D2-5 16:20

Facial Expression Recognition as Markers of Depression

Jia Xuan Gue (Monash University, Malaysia); Chun Yong Chong (School of Information Technology, Monash University, Malaysia); Mei Kuan Lim (Monash University Malaysia & Monash University, Malaysia)

D2-6 16:40

How Transferable are Herbarium-Field Features in Few-Shot Plant Identification with Triplet Loss?

Sophia Chulif (Swinburne University of Technology Sarawak Campus, Malaysia); Sue Han Lee (Swinburne University of Technology, Malaysia); Yang Loong Chang (Neuon AI Sdn. Bhd., Malaysia); Mark Tee Kit Tsun (Swinburne University of Technology, Malaysia); Kok Chin Chai (UNIMAS, Malaysia); Yi Lung Then (Universiti Malaysia Sarawak, Malaysia)

IF1 Industrial Forum 201A

Chair: Gwo-Giun Lee (National Central University, Taiwan) / Arun Kumar Sangaiah (National Yunlin University of Science & Technology, Taiwan)

F1-1

Machine Learning for Healthcare Applications

Stefan Winkler (Research Director, Asus Intelligent Cloud Services (AICS), Singapore / Associate Professor, National University of Singapore (NUS), Singapore)

IF1-2

AI - Global Trends and Opportunities

Karthi Madhavan (Country Head, Tata Consultancy Services, Taiwan)

November 1 (Wednesday) 15:00-17:00

BS1 Best Paper Competition 201B

Chair: Ching-Te Chiu (National Tsing Hua University, Taiwan) / Jia-Ching Wang (National Central University, Taiwan) / Toshihisa Tanaka (Tokyo University of Agriculture and Technology, Japan)

BS1-1 15:00

Enhancing Real-Time Semantic Segmentation with Textual Knowledge of Pre-Trained Vision-Language Model: A Lightweight Approach

Chia-Yi Lin (National Taiwan University, Taiwan); Jun-Cheng Chen (Academia Sinica, Taiwan); Ja-Ling Wu (National Taiwan University, Taiwan)

BS1-2 15:20

EEG Study on Anticipation of Difficulty for Upcoming Auditory Task

Song Zichen (Kyoto University, Japan); Hiroshi Higashi (Osaka University, Japan); Ishii Shin (Kyoto University, Japan)

BS1-3 15:40

Event-Related Potential in Rapid Serial Visual Presentation-Based Partial Face Cognition Depends on Visible Face Components

Ingon Chanpornpakdi and Toshihisa Tanaka (Tokyo University of Agriculture and Technology, Japan)

BS1-4 16:00

Residual, Mixer, and Attention: The Three-Way Combination for Streaming Wake Word Detection Framework

Sattaya Singkul (Kasikorn Business Technology Group, Thailand); Theerat Sakdejayont (Kasikorn Labs, Thailand); Tawunrat Chalothorn (Kasikorn Labs Kasikorn Business-Technology Group, Thailand)

BS1-5 16:20

Audio-To-Score Singing Transcription Based on Joint Estimation of Pitches, Onsets, and Metrical Positions with Tatum-Level CTC Loss

Tengyu Deng and Eita Nakamura (Kyoto University, Japan); Kazuyoshi Yoshii (Kyoto University & RIKEN, Japan)

BS1-6 16:40

Mask2Hand: Learning to Predict the 3D Hand Pose and Shape from Shadow

Li-Jen Chang, Yu-Cheng Liao and Chia Hui Lin (National Tsing Hua University, Taiwan); Shih-Fang Yang-Mao (Industrial Technology Research Institute, Taiwan); Hwann-Tzong Chen (National Tsing Hua University, Taiwan)

November 1 (Wednesday) 15:00-17:00

G2 Advanced Image and Video Processing Using Deep Learning 201C

Chair: Chul Lee (Dongguk University, Korea)

G2-1 15:00

Resolution-Adaptive Lossless Image Compression Using Frequency Decomposition Network

Hochang Rhee and Nam Ik Cho (Seoul National University, Korea)

G2-2 15:20

Implementation and Analysis on Backpropagating Refinement Scheme for Interactive Image Segmentation

Chaewon Lee (Korea University, Korea (South)); Won-Dong Jang (Korea University & Media Communications Lab, Korea (South)); Chang-Su Kim (Korea University, Korea (South))

G2-3 15:40

Implicit Neural Representation for Video Coding Through Progressive Feature Extraction

Jihoo Lee and Jewon Kang (Ewha Womans University, Korea)

G2-4 16:00

Deep Unfolded Underwater Image Enhancement Based on Extreme Channels Prior

Thuy T. Pham, Truong T. N Mai and Chul Lee (Dongguk University, Korea)

G2-5 16:20

Low-Light Image Enhancement via Distillation of NIR-To-RGB Conversion Knowledge

Young-Min Jeong, Tae-Sung Park, Jeong-Hyeok Park and Jong-Ok Kim (Korea University, Korea)

G2-6 16:40

3D Human Skeleton Estimation from Single RGB Image Based on Fusion of Predicted Depths from Multiple Virtual-Viewpoints

Wen-Nung Lie and Veasna Vann (National Chung Cheng University, Taiwan)

H2 Advanced Learning-based Computer Vision Technologies 201D

Chair: Chen-Kuo Chiang (National Chung Cheng University, Taiwan)

H2-1 15:00

GNN-Based Small-Data Learning with Area-Control Mechanism for Hyperspectral Satellite Change Detection

Tzu-Hsuan Lin, Chia-Hsiang Lin and Si-Sheng Young (National Cheng Kung University, Taiwan)

November 1 (Wednesday) 15:00-17:00

H2 Advanced Learning-based Computer Vision Technologies 201D

Chair: Chen-Kuo Chiang (National Chung Cheng University, Taiwan)

H2-2 15:20

Efficient Constraint-Aware Neural Architecture Search for Object Detection

Wei-Jie Hung, Egor Poliakov and Ching-Chun Huang (National Yang Ming Chiao Tung University, Taiwan)

H2-3 15:40

A Reliable Feature-Based Framework for Vehicle Tracking in Advanced Driver Assistance Systems

Ngoc-Quan Ha-Phan, Thanh-Nguyen Truong and Vu-Hoang Tran (Ho Chi Minh City University of Technology and Education, Vietnam); Ching-Chun Huang (National Yang Ming Chiao Tung University, Taiwan)

H2-4 16:00

Light-Weight Zero-Reference-Based Image Enhancement for Low-Light Images

Jie-Fan Chang (National Taiwan University, Taiwan); KuanTing Lai, Cheng-Xuan Zhuang, Guo-Shiang Lin and Ku-Yaw Chang (National Chin-Yi University of Technology, Taiwan)

H2-5 16:20

Class-Wise Self-Paced Self-Training for Semi-Supervised Image Classification

Cheng-Yu Lu, Heng-Cheng Hsu and Chen-Kuo Chiang (National Chung Cheng University, Taiwan)

H2-6 16:40

CapFormer: A Space-Time Video Description Model Using Joint-Attention Transformer

Mahamat Moussa, Chern Hong Lim and KokSheik Wong (Monash University Malaysia, Malaysia)

I2 Physics-Inspired Image Restoration and Enhancement 201E

Chair: Yuichi Tanaka (Osaka University, Japan)

I2-1 15:00

Local Contrast Enhancement with Multi-Scale Filtering

Kohei Hayashi (Nagoya Institute of Technology, Japan); Yoshihiro Maeda (Tokyo University of Science, Japan); Norishige Fukushima (Nagoya Institute of Technology, Japan)

I2-2 15:20

Marine Snow Removal Benchmarking Dataset

Reina Kaneko (Osaka University, Japan); Yuya Sato and Takumi Ueda (Tokyo University of Agriculture and Technology, Japan); Hiroshi Higashi and Yuichi Tanaka (Osaka University, Japan)

November 1 (Wednesday) 15:00-17:00

I2 Physics-Inspired Image Restoration and Enhancement 201E

Chair: Yuichi Tanaka (Osaka University, Japan)

I2-3 15:40

Cross-Frame Foreground Structural Similarity Modeling by Convolutional Sparse Representation

Kazuki Naganuma and Shunsuke Ono (Tokyo Institute of Technology, Japan)

I2-4 16:00

JPEG Artifact Removal for Hyperspectral Images Based on Spatial-Spectral Regularization

Ryunosuke Eguchi (The University of Kitakyushu, Japan); Iori Kobayashi (Japan); Shunsuke Ono (Tokyo Institute of Technology, Japan); Ryo Matsuoka (The University of Kitakyushu, Japan)

I2-5 16:20

Data Driven Multiband Image Fusion That Preserves Wavelength-Specific Image Features

Hsuan Lin and Hirakawa Keigo (University of Dayton, USA)

I2-6 16:40

Shot-Noise-Aware Image Signal Restoration for Photoelectronic Charge-Based Sensors

Seishi Takamura (Hosei University & NTT Corporation, Japan)

J2 IVM-2: Multimedia Generation and Synthesis 201F

Chair: Masaaki Ikehara (Keio University, Japan) / Shih-Hsuan Yang (National Taipei University of Technology, Taiwan)

J2-1 15:00

Generative Adversarial Network-Based Frame Interpolation with Multi-Perspective Discrimination

Quang Nhat Tran (Family Technology Company Limited, Vietnam); Shih-Hsuan Yang (National Taipei University of Technology, Taiwan)

J2-2 15:20

ArtHDR-Net: Perceptually Realistic and Accurate HDR Content Creation

Hrishav Bakul Barua (TCS Research Labs & TCS, India); Ganesh Krishnasamy and KokSheik Wong (Monash University Malaysia, Malaysia); Kalin Stefanov (Monash University, Australia); Abhinav Dhall (IIT Ropar, India)

J2-3 15:40

LSR++: An Efficient and Tiny Model for Image Super-Resolution

Wei Wang and Xuejing Lei (University of Southern California, USA); Yueru Chen (Peng Cheng Laboratory, China); Ming-Sui Lee (National Taiwan University, Taiwan); C.-C. Jay Kuo (University of Southern California, USA)

November 1 (Wednesday) 15:00-17:00

J2 IVM-2: Multimedia Generation and Synthesis 201F

Chair: Masaaki Ikehara (Keio University, Japan) / Shih-Hsuan Yang (National Taipei University of Technology, Taiwan)

J2-4 16:00

High-Quality Font Generation Based on StyleGAN2 and FSFont Font Generation Model

Yuki Shimamura and Michiharu Niimi (Kyushu Institute of Technology, Japan)

J2-5 16:20

Enhanced Residual Fourier Transformation Network for Lightweight Image Super-Resolution

Yunming Yang and Masaaki Ikehara (Keio University, Japan)

J2-6 16:40

ELEGANT: End-To-End Language Grounded Speech Denoiser for Efficient Generation of Talking Face

Arghya Pal, Sailaja Rajanala, Ai Fang Chai, Raphael C.-W. Phan and Chee-Ming Ting (Monash University, Malaysia)

November 2 (Thursday) 09:00-10:40

A3 SLA-III: Speech Emotion Recognition 101AB

Chair: Bagus Tris Atmaja (National Institute of Advanced Industrial Science and Technology, Japan)

A3-1 09:00

Speech Emotion Recognition by Late Fusion of Linguistic and Acoustic Features Using Deep Learning Models

Kiyohide Sato, Keita Kishi and Tetsuo Kosaka (Yamagata University, Japan)

A3-2 09:20

Multilingual, Cross-Lingual, and Monolingual Speech Emotion Recognition on EmoFilm Dataset

Bagus Tris Atmaja (National Institute of Advanced Industrial Science and Technology & Institut Teknologi Sepuluh Nopember, Japan); Akira Sasou (National Institute of Advanced Industrial Science and Technology, AIST, Japan)

A3-3 09:40

Ensembling Multilingual Pre-Trained Models for Predicting Multi-Label Regression Emotion Share from Speech

Bagus Tris Atmaja (National Institute of Advanced Industrial Science and Technology & Institut Teknologi Sepuluh Nopember, Japan); Akira Sasou (National Institute of Advanced Industrial Science and Technology, AIST, Japan)

A3-4 10:00

An Automatic Pipeline for Building Emotional Speech Dataset

Anh Thi Ngoc Anh, Hai Van Do, Nhat Minh Le and Thang Bao Ta (Viettel Cyberspace Center, Viettel Group, Vietnam)

A3-5 10:20

Analysis of Emotions in Speech Using AESDD

Uthiraa S and Hemant A. Patil (Dhirubhai Ambani Institute of Information and Communication Technology, India)

November 2 (Thursday) 09:00-10:40

B3 Acoustic Scene Analysis and Signal Enhancement Based on Advanced Signal Processing and Machine Learning — 101C

Chair: Shoji Makino (Waseda University, Japan) / Hiroshi Saruwatari (The University of Tokyo, Japan)

B3-1 09:00

Modified Parametric Multichannel Wiener Filter for Low-Latency Enhancement of Speech Mixtures with Unknown Number of Speakers

Ning Guo (International Audio Laboratories Erlangen, Germany); Tomohiro Nakatani (NTT Corporation, Japan); Shoko Araki (NTT Communication Science Laboratories, Japan); Takehiro Moriya (NTT, Japan)

B3-2 09:20

Blind Source Separation Using Independent Low-Rank Matrix Analysis with Spectrogram-Consistency Regularization

Sota Misawa (The University of Tokyo & AKARI Inc., Japan); Norihiro Takamune (The University of Tokyo, Japan); Kohei Yatabe (Tokyo University of Agriculture and Technology, Japan); Daichi Kitamura (National Institute of Technology, Kagawa College, Japan); Hiroshi Saruwatari (The University of Tokyo, Japan)

B3-3 09:40

Moving Interference Speaker Removal Using Geometrically Constrained Independent Vector Analysis

Shinya Furunaga, Tetsuya Ueda and Shoji Makino (Waseda University, Japan)

B3-4 10:00

A Dual-Channel Three-Stage Model for DoA and Speech Enhancement

Meng-Hsuan Wu, Yih Liang Shen and Hsuan-Cheng Chou (National Yang Ming Chiao Tung University, Taiwan); Bo-Wun Shih (Realtek Semiconductor Corporation, Taiwan); Tai-Shih Chi (National Yang Ming Chiao Tung University, Taiwan)

B3-5 10:20

A Weighted Binary Cross-Entropy for Sound Event Representation Learning and Few-Shot Classification

Zhongxin Bai, Chao Pan and Gong Chen (Northwestern Polytechnical University, China); Jingdong Chen (Northwestern Polytechnical University, USA); Jacob Benesty (INRS-EMT, University of Quebec, Canada)

C3 Intelligent Recognition Applications — 101D

Chair: Chuan-Yu Chang (National Yunlin University of Science and Technology, Taiwan)

C3-1 09:00

A Reconfigurable Hardware Architecture for Graph Convolution Network in Action Recognition

Tsung-Han Tsai and Tzu-Chieh Chen (National Central University, Taiwan)

November 2 (Thursday) 09:00-10:40

C3 Intelligent Recognition Applications 101D

Chair: Chuan-Yu Chang (National Yunlin University of Science and Technology, Taiwan)

C3-2 09:20

Automated Carina Detection in Chest X-Ray Images Using Non-Overlapping and Cross-Squeeze Convolutional Neural Networks

Chung-Chian Hsu, Chi-Yuan Chen, S M Salahuddin Morsalin and Arthur Chang (National Yunlin University of Science and Technology, Taiwan); Wen-Lin Fan (Dalin Tzu Chi Hospital, Buddhist Tzu Chi Medical Foundation, Taiwan)

C3-3 09:40

Identifying the Style of Chatting

Manman Zhang, Yuchen Ma, Ge Luo, Sheng Li, Zhenxing Qian and Xinpeng Zhang (Fudan University, China)

C3-4 10:00

Pose-Based Visual Servoing with Lightweight Deep-Learning Binarization for Autonomous Mobile Robot Application

Chian C. Ho (National Yunlin University of Science and Technology, Taiwan)

C3-5 10:20

Integration of Contextual Information with YOLOv5 for Detecting Tracheobronchial Foreign Objects

Chuan-Yu Chang (National Yunlin University of Science and Technology, Taiwan); Chun-Liang Lai (Dalin Tzu Chi Hospital, Taiwan); Yu Shan Peng and Roshana Mukhtar (National Yunlin University of Science and Technology, Taiwan)

D3 Signal and Information Processing Theory and Methods 102

Chair: Shuichi Ohno (Osaka Metropolitan University, Japan)

D3-1 09:00

Real-Time Noise Suppression Using Harmonic/Percussive Separation with Morphological Operations for Hammering Test

Ryugo Uchiyama and Nari Tanabe (Suwa University of Science, Japan)

D3-2 09:20

ΔΣ Modulators for Discrete-Time Closed Loop Control Systems with Quantization and Saturation

Shuichi Ohno and Shenjian Wang (Osaka Metropolitan University, Japan); Kiyotsugu Takaba (Ritsumeikan University, Japan)

November 2 (Thursday) 09:00-10:40

D3 Signal and Information Processing Theory and Methods 102

Chair: Shuichi Ohno (Osaka Metropolitan University, Japan)

D3-3 09:40

Asymptotic Estimation Performance of Linear Regression Model with Sparse Bayesian Learning as Both Samples and Signals Approach Infinity

Kazuaki Murayama (The University of Electro-Communications, Japan)

D3-4 10:00

Convolutional Multidimensional Amplitude Spectrum Nuclear Norm for Frequency-Domain Robust Principal Component Analysis

Ryoya Harashima (Kogakuin University, Japan); Ryunosuke Eguchi (The University of Kitakyushu, Japan); Seisuke Kyochi (Kogakuin University, Japan)

D3-5 10:20

Moreau Envelope ADMM for Decentralized Weakly Convex Optimization

Reza Mirzaeifard (Norwegian University of Science and Technology, Norway); Naveen K. D. Venkategowda (Linköping University, Sweden); Alexander Jung (Aalto University, Finland); Stefan Werner (NTNU, Norway)

E3 SLA-IV: Speech Enhancement 201A

Chair: Chih-Peng Fan (National Chung Hsing University, Taiwan)

E3-1 09:00

An Audio-Visual Speech Enhancement System Based on 3D Image Features: An Application in Hearing Aids

Yu-Ching Chung, Ji-Yan Han, Bo-Sin Wang, Wei-Zhong Zheng, Kung-Yao Shen and Ying-Hui Lai (National Yang Ming Chiao Tung University, Taiwan)

E3-2 09:20

On Joint Dereverberation and Source Separation with Geometrical Constraints and Iterative Source Steering

Kaien Mo (Waseda University, Japan); Xianrui Wang (Center of Intelligent Acoustics and Immersive Communications, China); Yichen Yang (Northwestern Polytechnical University, China); Tetsuya Ueda and Shoji Makino (Waseda University, Japan); Jingdong Chen (Northwestern Polytechnical University, USA)

E3-3 09:40

Study of Generative Adversarial Networks for Noisy Speech Simulation from Clean Speech

Leander Melroy Maben (Manipal Academy of Higher Education, India); Guo Zixun and Chen Chen (Nanyang Technological University, Singapore); Utkarsh Chudiwal (Indian Institute of Technology, India); Eng-Siong Chng (Nanyang Technological University, Singapore)

November 2 (Thursday) 09:00-10:40

E3 SLA-IV: Speech Enhancement 201A

Chair: Chih-Peng Fan (National Chung Hsing University, Taiwan)

E3-4 10:00

Step Size Control of Shared-Error Normalized Least Mean Square Algorithm for Acoustic Echo and Noise Canceller

Kenta Iwai and Takanobu Nishiura (Ritsumeikan University, Japan)

E3-5 10:20

Enhancing Spectrogram for Audio Classification Using Time-Frequency Enhancer

Haoran Xing and Shiqi Zhang (Waseda University, Japan); Daiki Takeuchi, Daisuke Niizumi and Noboru Harada (NTT Corporation, Japan); Shoji Makino (Waseda University, Japan)

F3 SLA-V: Text-to-Speech and Voice Conversion 201B

Chair: Masanobu Abe (Okayama University, Japan) / Tomoki Toda (Nagoya University, Japan)

F3-1 09:00

Evaluating Methods for Ground-Truth-Free Foreign Accent Conversion

Wen-Chin Huang and Tomoki Toda (Nagoya University, Japan)

F3-2 09:20

DisC-VC: Disentangled and F0-Controllable Neural Voice Conversion

Chihiro Watanabe (NTT Communication Science Laboratories, Japan); Hirokazu Kameoka (Nippon Telegraph and Telephone Corporation, Japan)

F3-3 09:40

Speech Synthesis Using Ambiguous Inputs from Wearable Keyboards

Matsuri Iwasaki, Sunao Hara and Masanobu Abe (Okayama University, Japan)

F3-4 10:00

Accent-Preserving Voice Conversion Between Native-Nonnative Speakers for Second Language Learning

Iago Lourenco Correa, Sei Ueno and Akinobu Lee (Nagoya Institute of Technology, Japan)

F3-5 10:20

Increasing Speech Intelligibility by Mimicking Professional Announcers' Voices and Its Physical Correlates

Dung Kim Tran, Akagi Masato and Masashi Unoki (Japan Advanced Institute of Science and Technology, Japan)

November 2 (Thursday) 09:00-10:40

G3 Distributed and Multi-task Learning Algorithms and Applications 201C

Chair: Yih-Fang Huang (University of Notre Dame, USA) / Anthony Kuh (University of Hawaii at Manoa, USA)

G3-1 09:00

Robust Networked Federated Learning for Localization

Reza Mirzaeifard (Norwegian University of Science and Technology, Norway); Naveen K. D. Venkategowda (Linköping University, Sweden); Stefan Werner (NTNU, Norway)

G3-2 09:20

Continual Local Updates for Federated Learning with Enhanced Robustness to Link Noise

Ehsan Lari (Norwegian University of Science and Technology, Norway); Vinay Chakravarthi Gogineni (University of Southern Denmark, Norway); Reza Arablouei (CSIRO, Australia); Stefan Werner (NTNU, Norway)

G3-3 09:40

Gaussian Process Learning for Location-Based Service Data

Ekin Ugurel, Shuai Huang and Cynthia Chen (University of Washington, USA)

G3-4 10:00

Distributed On-Line Anomaly Detection Using Kernel Methods

Anthony Kuh and Tyler Baguio (University of Hawaii, Manoa, USA)

G3-5 10:20

Communication-Efficient Design of Leaning System for Energy Demand Forecasting of Electrical Vehicles

Jiacong Xu (Johns Hopkins University, USA); Riley Kilfoyle and Zixiang Xiong (Texas A&M University, USA); Ligang Lu (Shell Intl. E&P, USA)

H3 Recent Advances on Signal and Information Processing for Active Control of Sound 201D

Chair: Yoshinobu Kajikawa (Kansai University, Japan)

H3-1 09:00

Radiated Sound Field Reproduction for Surrounding Loudspeaker Array Based on Higher-Order Ambisonics

Shota Naiki, Shumpei Miura, Kenta Iwai and Takanobu Nishiura (Ritsumeikan University, Japan); Yoshiharu Soeta (National Institute of Advanced Industrial Science and Technology (AIST), Japan)

November 2 (Thursday) 09:00-10:40

H3 Recent Advances on Signal and Information Processing for Active Control of Sound — 201D

Chair: Yoshinobu Kajikawa (Kansai University, Japan)

H3-2 09:20

Multichannel Learning-Based Spatially Extended Active Noise Control via Model Matching and Sensor Transfer Function Interpolation

Pei-Lin Zhong, You-Siang Chen and Mingsian Bai (National Tsing Hua University, Taiwan)

H3-3 09:40

A Study of the Microphone Protection of Active Noise Control for Axial Fan

Yi-Tsung Shen and Cheng-Yuan Chang (Chung Yuan Christian University, Taiwan)

H3-4 10:00

SFANC with Compensation Filter Based on MEFxDCTLMS Algorithm

Kenya Doi and Yoshinobu Kajikawa (Kansai University, Japan)

H3-5 10:20

Practical Active Noise Control: Restriction of Maximum Output Power

Woon Seng Gan and Dong-Yuan Shi (Nanyang Technological University, Singapore); XiaoYi Shen (NTU, Singapore)

I3 Selected Papers from APSIPA Workshop in Bandung, Indonesia (II) — 201E

Chair: Trio Adiono (Institut Teknologi Bandung, Indonesia)

I3-1 09:00

A QoS Throughput Performance Measurement Comparison Between UGS and BE Services of a Real-Time FPGA Based OFDM Multi-User System Design Implementation

Trio Adiono, Michael Jonathan, Erwin Setiawan, Nana Sutisna and Rahmat Mulyawan (Institut Teknologi Bandung, Indonesia); Infall Syafalni (Bandung Institute of Technology, Indonesia)

I3-2 09:20

Algorithm Development for Step-Wise Valve Deflation Method in Blood Pressure Measurement

Trio Adiono (STEI ITB, Indonesia); Reina Puteri Ramadhani and Clarence Amadeus (Bandung Institute of Technology, Indonesia); Sindy Novaria Cicilya Sinaga (PT. Xirka Dama Persada, Indonesia)

November 2 (Thursday) 09:00-10:40

I3 Selected Papers from APSIPA Workshop in Bandung, Indonesia (II) 201E

Chair: Trio Adiono (Institut Teknologi Bandung, Indonesia)

I3-3 09:40

SUMO Based Hardware/Software Co-Simulation for Two-Intersection Adaptive and Collaborative Traffic Signal Controller

Kendrik Emkel Ginting and Nana Sutisna (Institut Teknologi Bandung, Indonesia); Infall Syafalni (Bandung Institute of Technology, Indonesia); Trio Adiono (Institut Teknologi Bandung, Indonesia)

I3-4 10:00

Sparsity Exploration for Structured and Unstructured Weight Formations in CNN Architecture

Devi Noor Endrawati and Infall Syafalni (Bandung Institute of Technology, Indonesia); Nana Sutisna (Institut Teknologi Bandung, Indonesia); Trio Adiono (STEI ITB, Indonesia)

J3 Selected Papers from APSIPA Workshop in Hanoi, Vietnam (II) 201F

Chair: Nguyen Linh Trung (Vietnam National University, Hanoi, Vietnam)

J3-1 09:00

1M Parameters are Enough? A Lightweight CNN-Based Model for Medical Image Segmentation

Binh-Duong Dinh, Thanh-Thu Nguyen, Thi-Thao Tran and Van-Truong Pham (Hanoi University of Science and Technology, Vietnam)

J3-2 09:20

Imaging Ultrasound Scattering Targets Using Density-Enhanced Chaotic Compressive Sampling

Tran Thi Thuy Quynh (VNU University of Engineering and Technology, Vietnam); Theu Luong Thi (Hoa Binh University, Vietnam); Tran Quang-Huy (Ha Noi Pedagogical University No2, Vietnam); Tran Duc-Tan (Phenikaa University, Vietnam)

J3-3 09:40

Segmentation and Observation of Hand Rehabilitation Exercises by Supporting of Acceleration Signals

Vu Hai (Ha Noi University of Science and Tenology, Vietnam); Nguyen Sinh Huy (Military Institute of Science and Technology, Vietnam); Le Thi Thu Hong (Military Institute of Science and Technology & MIST, Vietnam); Nguyen Hoang Bach (Military Institute of Science and Technology, Vietnam); Bach Ngoc Duong (HUST, Vietnam); Thanh Nguyen Chi (Institute of Information Technology, AMST, Vietnam); Nguyen Van Loi (Hanoi University of Science and Technology, Vietnam)

November 2 (Thursday) 09:00-10:40

J3 Selected Papers from APSIPA Workshop in Hanoi, Vietnam (II) 201F

Chair: Nguyen Linh Trung (Vietnam National University, Hanoi, Vietnam)

J3-4 10:00

Investigating the Role of Human Action Detector in Visual-Guide Audio Source Separation System

Thanh Thi-Hien Duong (Hanoi University of Mining and Geology, Vietnam & Hanoi University of Science and Technology, Vietnam); Trung-Hieu Nguyen and Thanh-Dat The Le (Hanoi University of Science and Technology, Vietnam); Thi-Lich Nghiem (Thuongmai University, Vietnam); Duc-Huy Pham (Hanoi University of Science and Technology, Vietnam); Thi-Lan Le (School of Electrical and Electronic Engineering (SEEE), HUST, Vietnam)

J3-5 10:20

A Combination of Time and Frequency Synchronization with Doppler Compensation in Coded OFDM-Based UWA Systems

Nguyen Thi Hoai Linh (Ha Noi University of Science and Technology, Vietnam); Quoc Khuong Nguyen and Nguyen Van Duc (HUST, Vietnam)

November 2 (Thursday) 13:30-15:30

A4 IVM-3: Multimedia Representation and Identification 101AB

Chair: Zhaojie Luo (Osaka University, Japan) / Mei-Chen Yeh (National Taiwan Normal University, Taiwan)

A4-1 13:30

ResNet-Based Camera Model Identification with Adaptive Preprocessing Module and Weight Fusion of Global Information

Boru Chen and Waleed H. Abdulla (The University of Auckland, New Zealand)

A4-2 13:50

Structural Quality Assured Global Optimization for CTU-Level Rate Control of Screen Content Coding

Tong Tang, Yuan Tan, Shihang Ding and Zhidu Li (Chongqing University of Posts and Telecommunications, China)

A4-3 14:10

Multi-Modal Emotion Recognition Based on 2D Kernel Density Estimation for Multiple Labels Fusion

Zhaojie Luo and Kazunori Komatani (Osaka University, Japan)

A4-4 14:30

RobustL2S: Speaker-Specific Lip-To-Speech Synthesis Exploiting Self-Supervised Representations

Neha Sahipjohn, Neil Shah, Vishal Tambrahalli and Vineet Gandhi (IIIT Hyderabad, India)

A4-5 14:50

Realizing Nipple in Profile Recognition and Nipple Detection Using a Single Classification

Yi-Chong Zeng (Institute for Information Industry, Taiwan)

A4-16 15:10

Exploring a CLIP-Enhanced Automated Approach for Video Description Generation

Siang-Ling Zhang, Huai-Hsun Cheng, Yen-Hsin Chen and Mei-Chen Yeh (National Taiwan Normal University, Taiwan)

November 2 (Thursday) 13:30-15:30

B4 Innovative Technology on 3D Point Cloud and Image Processing 101C

Chair: Seishi Takamura (Hosei University / NTT Corporation, Japan)

B4-1 13:30

3D Point Cloud Denoising Based on Color Attribute

Wei-Chi Lin (Chung Yuan Christian University, Taiwan); Ming Zhan Lee (National Cheng Kung University, Taiwan); He-Sheng Chou, Yuan-Jin Lin and Li Kuo-Chen (Chung Yuan Christian University, Taiwan); Ting-Lan Lin (National Taipei University of Technology, Taiwan); Shih-Lun Chen (Chung Yuan Christian University, Taiwan)

B4-2 13:50

The DSP and DDR4 VLSI Design for Multi-Sensor in Biomedical System

Jia-Sheng Zhang (Ming Chi University, Taiwan); Chiung-An Chen (Ming Chi University of Technology, Taiwan); Shih-Lun Chen (Chung Yuan Christian University, Taiwan)

B4-3 14:10

Identification of Victims Wearing Vibrant Clothing Using MATLAB

Hao-Cheng Lu and Chiung-An Chen (Ming Chi University of Technology, Taiwan)

B4-4 14:30

Point Cloud Inpainting Based on Delaunay Triangulation

Yu-Lin Liu and He-Sheng Chou (Chung Yuan Christian University, Taiwan); Ming Zhan Lee (National Cheng Kung University, Taiwan); Mei-Ling Chan (Jiaying University, China); Ting-Lan Lin (National Taipei University of Technology, Taiwan); Shih-Lun Chen (Chung Yuan Christian University, Taiwan)

B4-5 14:50

Dense Three-Dimensional Color Reconstruction for Large-Scale Outdoor Scenes

Zixiao Liu (The Chinese University of Hong Kong, Shenzhen, China); Sheng Guo (Guangming Research Labs, Hong Kong); Man-On Pun (The Chinese University of Hong Kong, Shenzhen, China)

B4-6 15:10

Safety Enhancement for Mobility Scooter with Rule-Based Danger Prevention

Yan-Ru Chen (Chang Gung University, Taiwan)

C4 Machine Learning under Data-Constrained Conditions 101D

Chair: Jen-Tzung Chien (National Yang Ming Chiao Tung University, Taiwan)

C4-1 13:30

Dictionary-Driven Chinese ASR Entity Correction with Controllable Decoding

Rongjun Li and Wei Peng (Huawei Technologies, Co., Ltd., China)

November 2 (Thursday) 13:30-15:30

C4 Machine Learning under Data-Constrained Conditions 101D

Chair: Jen-Tzung Chien (National Yang Ming Chiao Tung University, Taiwan)

C4-2 13:50

A Method of Efficient Synthesizing Post-Disaster Remote Sensing Image with Diffusion Model and LLM

Ruizhe Ou, Ming Wu, Chuang Zhang and Haotian Yan (Beijing University of Posts and Telecommunications, China)

C4-3 14:10

Privacy-Oriented Coded Caching in Mobile Information-Centric Network

Binchen Yang, Yu Guo and Xingyan Chen (Southwestern University of Finance and Economics, China)

C4-4 14:30

MKTformer: Fine-Grained Meter Classification Based on Multi-Modal Knowledge Transfer

Zhaoye Zheng, Zhang Ke and Chaojun Shi (North China Electric Power University, China)

C4-5 14:50

Feature Augmentation Reconstruction Network for Few-Shot Image Classification

Zhen Li, Lang Wang, Wenjuan An, Qi Song and Xiaoxu Li (Lanzhou University of Technology, China); Xuezhi Fei (Machinery Industry Shanghai Lanya Petrochemical Equipment Testing Institute, China)

C4-6 15:10

Dual Feature Reconstruction Network Based on Few-Shot Image Classification

Xiaowei Guo, Jijie Wu, Kai Ren, Qi Song and Xiaoxu Li (Lanzhou University of Technology, China)

D4 Signal Processing and Artificial Intelligence in Biomedicine and Healthcare 102

Chair: Jian-Jia Huang (Chang Gung University, Taiwan)

D4-1 13:30

A Cloud-Based Data Platform for Efficient EEG Data Management, Collaboration, and Analysis

Qi Tian, Wen Wu, Qin Zhu, Tao Cai, Siyi Jiang, Yaqing Li, Jinrun Zhou, Nan Zhu, Yina Wei and Tao Tang (Zhejiang Lab, China); Kedi Xu (Qiushi Academy for Advanced Studies, Zhejiang University, China); Feng Lin and Linqing Feng (Zhejiang Lab, China)

November 2 (Thursday) 13:30-15:30

D4 Signal Processing and Artificial Intelligence in Biomedicine and Healthcare — 102

Chair: Jian-Jia Huang (Chang Gung University, Taiwan)

D4-2 13:50

Incorporating the Digit Triplet Test in A Lightweight Speech Intelligibility Prediction for Hearing Aids

Xiajie Zhou, Candy Olivia Mawalim, Benita Angela Titalim and Masashi Unoki (Japan Advanced Institute of Science and Technology, Japan)

D4-3 14:10

Deep Learning-Based MRI Super-Resolution Using Non-Uniform Segmented Phase-Scrambling Fourier Transform Signals

Kazuki Yamato, Shuntaro Fujisawa and Satoshi Ito (Utsunomiya University, Japan)

D4-4 14:30

An Extreme Gradient Boosting-Based Prediction for Depression

Ahmed Dawod Mohammed Ibrahum (Chungbuk National University, Korea)

D4-5 14:50

An Improved Check Digit-Based Participant Identification System for Human Biorepositories

Minseok Chu (Chungbuk University & National Institute of Health, Korea); Keunho Ryu (Ton Duc Thang University, Vietnam and Chungbuk National University, Korea)

D4-6 15:10

Enhancing Snoring Detection with Statistical Analysis of Audio Features

Suphachok Buaruk and Somrudee Deepaisarn (Sirindhorn International Institute of Technology, Thammasat University, Thailand)

E4 Artificial Intelligence (AI) for Multimedia Processing and Applications — 201A

Chair: Tsung-Jung Liu (National Chung Hsing University, Taiwan) / Kuan-Hsien Liu (National Taichung University of Science and Technology, Taiwan)

E4-1 13:30

Un-Rectifying in ReLU Networks and Applications

Shih-Shuo Tung (Academia Sinica, Taiwan); Ming-Yu Chung (National Taiwan University, Taiwan); Jinn Ho and Wen-Liang Hwang (Academia Sinica, Taiwan)

November 2 (Thursday) 13:30-15:30

E4 Artificial Intelligence (AI) for Multimedia Processing and Applications — 201A

Chair: Tsung-Jung Liu (National Chung Hsing University, Taiwan) / Kuan-Hsien Liu (National Taichung University of Science and Technology, Taiwan)

E4-2 13:50

OpenPose Based Yoga Poses Difficulty Estimation for Dynamic and Static Yoga Exercises

Wan-Chia Huang and Cheng-Liang Shih (National Chung Hsing University, Taiwan); Irin Tri Anggraini, Yanqi Xiao and Nobuo Funabiki (Okayama University, Japan); Chih-Peng Fan (National Chung Hsing University, Taiwan)

E4-3 14:10

Multimodal Multifaceted Music Emotion Recognition Based on Self-Attentive Fusion of Psychology-Inspired Symbolic and Acoustic Features

Jiahao Zhao and Eita Nakamura (Kyoto University, Japan); Kazuyoshi Yoshii (Kyoto University & RIKEN, Japan)

E4-4 14:30

Learned String Quartet Music with Variational Auto Encoder

Young-Long Chen, Hsin-I Huang and Tzu-Te Yen (National Taichung University of Science and Technology, Taiwan)

E4-5 14:50

SOAda-YOLOR: Small Object Adaptive YOLOR Algorithm for Road Object Detection

Yu-Fang Huang, Tsung-Jung Liu and Chun-An Lin (National Chung Hsing University, Taiwan); Kuan-Hsien Liu (National Taichung University of Science and Technology, Taiwan)

E4-6 15:10

Badminton Self-Training System Based on Virtual Reality

Wei-Shen Tai and Kuan-Hsien Liu (National Taichung University of Science and Technology, Taiwan)

F4 Emerging Trends in Privacy, Multimedia Security and Forensics: Deep Learning and AI Approaches — 201B

Chair: Ahmed Khan (Monash University Malaysia, Malaysia) / Minoru Kuribayashi (Tohoku University, Japan)

F4-1 13:30

Rotation Angle Detection Using a Pilot Signal from Rotated Stego-Image

Rinka Kawano and Masaki Kawamura (Yamaguchi University, Japan)

November 2 (Thursday) 13:30-15:30

F4 Emerging Trends in Privacy, Multimedia Security and Forensics: Deep Learning and AI Approaches — 201B

Chair: Ahmed Khan (Monash University Malaysia, Malaysia) / Minoru Kuribayashi (Tohoku University, Japan)

F4-2 13:50

Application for Generating Re-Accessible Screenshots of Web Pages Using Histogram Shrinkage

Ayaka Sakamoto, Rinka Kawano and Masaki Kawamura (Yamaguchi University, Japan)

F4-3 14:10

Domain Adaptation for Efficiently Fine-Tuning Vision Transformer with Encrypted Images

Teru Nagamori, Sayaka Shiota and Hitoshi Kiya (Tokyo Metropolitan University, Japan)

F4-4 14:30

Study on Face Landmark-Based Analysis for Synthetic Media Identification Generated by Adversarial Generative Networks

Akinobu Ura (Okayama University, Japan); Minoru Kuribayashi (Tohoku University, Japan); Nobuo Funabiki (Okayama University, Japan)

F4-5 14:50

HDR Image Watermarking Based on Saliency Detection and Quantization Index Modulation

Ahmed Khan (Monash University, Malaysia); Minoru Kuribayashi (Tohoku University, Japan); KokSheik Wong and Vishnu Monn Baskaran (Monash University Malaysia, Malaysia)

F4-6 15:10

Quick Response (QR) Codes Embedding in VVC Using Quantisation Parameter Manipulation

Joan Hau (TARUMT, Malaysia); Li Peng Tan (Tunku Abdul Rahman University College, Malaysia); Yiqi Tew (Tunku Abdul Rahman University of Management and Technology, Malaysia)

G4 Intelligent Visual Data Processing, Analytics, and Representation — 201C

Chair: Ching-Chun Huang (National Yang Ming Chiao Tung University, Taiwan) / Shang-Hong Lai (National Tsing Hua University, Taiwan)

G4-1 13:30

CPIPS: Learning to Preserve Perceptual Distances in End-To-End Image Compression

Chen-Hsiu Huang and Ja-Ling Wu (National Taiwan University, Taiwan)

G4-2 13:50

Task-Specific Pruning: Efficient Parameter Reduction in Multi-Task Object Detection Models

Wei-Hsun Ke and Yu-Wen Tseng (National Yang Ming Chiao Tung University, Taiwan); Wen-Huang Cheng (National Taiwan University, Taiwan)

November 2 (Thursday) 13:30-15:30

G4 Intelligent Visual Data Processing, Analytics, and Representation 201C

Chair: Ching-Chun Huang (National Yang Ming Chiao Tung University, Taiwan) / Shang-Hong Lai (National Tsing Hua University, Taiwan)

G4-3 14:10

Transformer-Based Image Compression with Variable Image Quality Objectives

Chia-Hao Kao, Yi-Hsin Chen, Cheng Chien, Wei-Chen Chiu and Wen-Hsiao Peng (National Yang Ming Chiao Tung University, Taiwan)

G4-4 14:30

From Synthetic to Real: Enhancing Deep Learning Models with Generative Adversarial Networks for Efficient Data Utilization in Automatic Retail Stores

Cong-Ty Dang, Vu-Hoang Tran and Ngoc-Hoang-Lam Le (Ho Chi Minh City University of Technology and Education, Vietnam); Ching-Chun Huang (National Yang Ming Chiao Tung University, Taiwan)

G4-5 14:50

Virtual Garment Fitting Through Parsing and Context-Aware Generative Adversarial Networks with Discriminator Group

Wei-Hong Su, Sze-Ann Chen, Chen-I Chin and Hsu-Feng Hsiao (National Yang Ming Chiao Tung University, Taiwan)

G4-6 15:10

Sparse Tensor-Based Point Cloud Attribute Compression Using Augmented Normalizing Flows

Tzu-Po Lin, Monyneath Yim and Jui -Chiu Chiang (National Chung Cheng University, Taiwan); Wen-Hsiao Peng (National Yang Ming Chiao Tung University, Taiwan); Wen-Nung Lie (National Chung Cheng University, Taiwan)

H4 SLA-VI: Speech Recognition 201D

Chair: Cheng-Yuan Chang (Chung Yuan Christian University, Taiwan)

H4-1 13:30

Toward Leveraging Pre-Trained Self-Supervised Frontends for Automatic Singing Voice Understanding Tasks: Three Case Studies

Yuya Yamamoto (University of Tsukuba, Japan)

H4-2 13:50

Out-Of-Vocabulary Word Detection in Spoken Dialogues Based on Joint Decoding with User Response Patterns

Miki Oshio, Hokuto Munakata, Ryu Takeda and Kazunori Komatani (Osaka University, Japan)

November 2 (Thursday) 13:30-15:30

H4 SLA-VI: Speech Recognition 201D

Chair: Cheng-Yuan Chang (Chung Yuan Christian University, Taiwan)

H4-3 14:10

Synthetic Data Augmentation for ASR with Domain Filtering

Tuan Vu Ho and Shota Horiguchi (Hitachi Ltd., Japan); Shinji Watanabe (Carnegie Mellon University, USA); Leibny Paola Garcia Perera (Johns Hopkins University, USA); Takashi Sumiyoshi (Central Research Laboratory, Hitachi Ltd., Japan)

H4-4 14:30

Multi-Self-Supervised Learning Model-Based Throat Microphone Speech Recognition

Kohta Masuda (Shizuoka University, Japan); Jun Ogata (National Institute of Advanced Industrial Science and Technology (AIST), Japan); Masafumi Nishida (Shizuoka University, Japan); Masafumi Nishimura (Shizuoka University, Japan and Aichi Sangyo University, Japan)

H4-5 14:50

ASR Model Adaptation for Rare Words Using Synthetic Data Generated by Multiple Text-To-Speech Systems

Kwok Chin Yuen, Li Haoyang and Eng-Siong Chng (Nanyang Technological University, Singapore)

H4-6 15:10

Streaming End-To-End ASR Using CTC Decoder and DRA for Linguistic Information Substitution

Tatsunari Takagi and Norihide Kitaoka (Toyohashi University of Technology, Japan); Atunori Ogawa (Nippon Telegraph and Telephone Corporation, Japan); Wakabayashi Yukoh (Toyohashi University of Technology, Japan)

I4 New Frontiers in Biometric Authentication 201E

Chair: Koichi Ito (Tohoku University, Japan)

I4-1 13:30

A Biometric Signature Scheme with Template Protection and Authenticated Sample Recoverability

Wataru Nakamura (Hitachi, Ltd., Japan); Kenta Takahashi (Hitachi, Ltd. & University of Tokyo, Japan)

I4-2 13:50

IPFed: Identity Protected Federated Learning for User Authentication

Yosuke Kaga and Yusei Suzuki (Hitachi Ltd., Japan); Kenta Takahashi (Hitachi Ltd. & University of Tokyo, Japan)

November 2 (Thursday) 13:30-15:30

I4 New Frontiers in Biometric Authentication 201E

Chair: Koichi Ito (Tohoku University, Japan)

I4-3 14:10

Privacy-Preserving Image Transformation Method for Person Detection and Re-ID

Yumo Ouchi, Hidetsugu Uchida and Narishige Abe (Fujitsu Limited, Japan)

I4-4 14:30

Eye Biometrics Combined with Periocular and Iris Recognition Using CNN

Taito Tonosaki, Shokei Kawakami, Koichi Ito and Takafumi Aoki (Tohoku University, Japan); Yoshiko Yasumura, Masakazu Fujio and Yosuke Kaga (Hitachi Ltd., Japan); Kenta Takahashi (Hitachi Ltd. & University of Tokyo, Japan)

I4-5 14:50

Development of a Robust Ear Recognition Algorithm Using Planar Approximation

Takahiko Arakawa and Yuya Sato (Shizuoka University, Japan); Hitoshi Sakano (Shimane University, Japan); Tetsushi Ohki (Shizuoka University, Japan)

OS1 Overview Section (I) 201F

Chair: Chuan-Yu Chang (National Yunlin University of Science and Technology, Taiwan)

OS1-1 13:30

Detecting Situs Inversus in Chest Radiographs

Chuan-Yu Chang (National Yunlin University of Science and Technology, Taiwan)

OS1-2 13:50

Fully Automatic Prediction and Selection of Ureteral Stone Lithotripsy Based on Enhanced-ResStage-UNet3+ Ureteral Stone Segmentation and Stacking-Ensemble-Learning Ureteral Stone Analysis

Chian C. Ho (National Yunlin University of Science and Technology, Taiwan)

OS1-3 14:10

Deep Learning Based Endotracheal Tube Detection System

Chung-Chian Hsu (National Yunlin University of Science and Technology, Taiwan)

November 3 (Friday) 09:00-10:40

A5 SLA-VII: Speech Separation and Tracking 101AB

Chair: Masahiro Yukawa (Keio University, Japan) / Yi-Wen Liu (National Tsing Hua University, Taiwan)

A5-1 09:00

Analysis of Speech Separation Performance Degradation on Emotional Speech Mixtures

Jia Qi Yip and Dianwen Ng (Nanyang Technological University & Alibaba Group, Singapore); Bin Ma (Alibaba Group, Singapore); Eng-Siong Chng (Nanyang Technological University, Singapore)

A5-2 09:20

Geometrically Constrained Blind Moving Source Extraction Based on Constant Separation Vector and Auxiliary Function Technique

Ruifeng Zhang, Tetsuya Ueda and Shoji Makino (Waseda University, Japan)

A5-3 09:40

Universal Sound Separation Using Replay-Based Data Sampling in Incremental Learning

Kanta Shimonishi, Takahiro Fukumori and Yoichi Yamashita (Ritsumeikan University, Japan)

A5-4 10:00

Multiple Sound Source Tracking Based on Generative Modeling and Recursive Bayesian Filtering of Spatial Gradient Spectra

Keisuke Takazawa (Keio University, Japan); Hirokazu Kameoka (Nippon Telegraph and Telephone Corporation, Japan); Masahiro Yukawa (Keio University, Japan)

A5-5 10:20

Spatially-Regularized Switching Independent Vector Analysis

Tetsuya Ueda (Waseda University, Japan); Tomohiro Nakatani and Rintaro Ikeshita (NTT Corporation, Japan); Shoko Araki (NTT Communication Science Laboratories, Japan); Shoji Makino (Waseda University, Japan)

B5 High Performance Image and Video Processing and Applications 101C

Chair: Kosin Chamnongthai (King Mongkut's University of Technology Thonburi, Thailand)

B5-1 09:00

ASF-LLRDA: Locality-Regularized Linear Regression Discriminant Analysis with Approximately Symmetrical Face Preprocessing for Face Recognition

Shintami Chusnul Hidayati and Arya Widyadhana (Institut Teknologi Sepuluh Nopember, Indonesia); Yeni Anistyasari (Universitas Negeri Surabaya, Indonesia)

B5-2 09:20

Joint Optimization Algorithm for Adaptive Bit Allocation Based on Temporal-Spatial Information

Shaokang Wang and Sun Songlin (Beijing University of Posts and Telecommunications, China)

November 3 (Friday) 09:00-10:40

B5 High Performance Image and Video Processing and Applications 101C

Chair: Kosin Chamnongthai (King Mongkut's University of Technology Thonburi, Thailand)

B5-3 09:40

Maximization of 2D Cross-Correlation Based on Auxiliary Function Method for Image Alignment

Yuma Kinoshita (Tokai University, Japan); Kouei Yamaoka and Hitoshi Kiya (Tokyo Metropolitan University, Japan)

B5-4 10:00

Multitask Record for Badminton Match

Jing-Ming Guo, Yu-Shun Huang, Ting-Yu Chang, Tai-Cyuan Ciou, Yun-Ching Yeh and Jeffrey Chen (National Taiwan University of Science and Technology, Taiwan)

B5-5 10:20

Deep Residual and Classified Neural Networks for Inverse Halftoning

Jing-Ming Guo, S Sankarasrinivasan and L v Hung (National Taiwan University of Science and Technology, Taiwan)

C5 Advanced Topics on Sound Event and Scene Analysis 101D

Chair: Nobutaka Ono (Tokyo Metropolitan University, Japan) / Keisuke Imoto (Doshisha University, Japan)

C5-1 09:00

DOA-Aware Audio-Visual Self-Supervised Learning for Sound Event Localization and Detection

Yoto Fujita (Kyoto University, Japan); Yoshiaki Bando (National Institute of Advanced Industrial Science and Technology, Japan); Keisuke Imoto (Doshisha University, Japan); Masaki Onishi (AIST, Japan); Kazuyoshi Yoshii (Kyoto University & RIKEN, Japan)

C5-2 09:20

Improving Sound Event Localization and Detection with Class-Dependent Sound Separation for Real-World Scenarios

Shi Cheng, Jun Du, Qing Wang, Ya Jiang, Zhaoxu Nian and Shutong Niu (University of Science and Technology of China, China); Chin-Hui Lee (Georgia Institute of Technology, USA); Yu Gao and Wenbin Zhang (AI Innovation Center, Midea Group (Shanghai) Co., Ltd., China)

C5-3 09:40

Joint Analysis of Acoustic Scenes and Sound Events Based on Semi-Supervised Approach

Ami Igarashi and Shunsuke Tsubaki (Doshisha University, Japan); Daisuke Niizumi, Daiki Takeuchi, Yasunori Ohishi and Noboru Harada (NTT Corporation, Japan); Keisuke Imoto (Doshisha University, Japan)

November 3 (Friday) 09:00-10:40

C5 Advanced Topics on Sound Event and Scene Analysis 101D

Chair: Nobutaka Ono (Tokyo Metropolitan University, Japan) / Keisuke Imoto (Doshisha University, Japan)

C5-4 10:00

Cross-Domain Sound Recognition for Efficient Underwater Data Analysis

Jeongsoo Park (Cochl, Korea); Hyoung Sul La (Korea Polar Research Institute, Korea); Yoonchang Han (Cochl Inc, Korea)

C5-5 10:20

Augmentation of Various Speed Data by Controlling Frame Overlap for Acoustic Traffic Monitoring

Tomohiro Takahashi (Tokyo Metropolitan University, Japan); Yuma Kinoshita (Tokai University, Japan); Natsuki Ueno (Tokyo Metropolitan University, Japan); Wakabayashi Yukoh (Toyohashi University of Technology, Japan & Tokyo Metropolitan University, Japan); Nobutaka Ono (Tokyo Metropolitan University, Japan); Jun Honda, Seishi Fukuma, Aoi Kitamori and Hiroshi Nakagawa (NEXCO-EAST Engineering, Japan)

D5 Modern Signal Analysis and Representation Methods and Their Applications 102

Chair: Jian-Jiun Ding (National Taiwan University, Taiwan)

D5-1 09:00

Distributed Computation of Heat Kernel Smoothing Using Series Expansion Method

Chien-Cheng Tseng (National Kaohsiung University of Science and Technology, Taiwan); Su-Ling Lee (Chang-Jung Christian University, Taiwan)

D5-2 09:20

In-Air Handwriting for Chinese Character Recognition from Monocular Camera: A Deep Learning Based Approach with Fingertip Detection and Virtual Strokes Elimination

Chih Chang Yu and Zi Hang Huang (Chung Yuan Christian University, Taiwan); Hsu-Yung Cheng (National Central University, Taiwan)

D5-13 09:40

EffSegmentNet: Efficient Design for Real-Time Semantic Segmentation

Cyun-Bo Wang and Jian-Jiun Ding (National Taiwan University, Taiwan)

D5-4 10:00

Universal Optimal Parameters of the Closed-Form Linear Canonical Wigner Distribution

Zhichao Zhang (Nanjing University of Information Science and Technology, China)

November 3 (Friday) 09:00-10:40

D5 Modern Signal Analysis and Representation Methods and Their Applications 102

Chair: Jian-Jiun Ding (National Taiwan University, Taiwan)

D5-5 10:20

Autoencoder-Enhanced Federated Learning with Reduced Overhead and Lower Latency

Chi-Kai Hsieh and Feng-Tsun Chien (National Yang Ming Chiao Tung University, Taiwan); Min-Kuan Chang (National Chung Hsing University, Taiwan)

E5 Digital Convergence of 5G/B5G, AIoT and Security 201A

Chair: Wen-Ping Lai (Yuan Ze University, Taiwan)

E5-1 09:00

Deep Unfolding-Based Distributed MIMO Detection

Masaya Kumagai, Ayano Nakai-Kasai and Tadashi Wadayama (Nagoya Institute of Technology, Japan)

E5-2 09:20

A Comparative Analysis of the Yolo Models for Intelligent Lobster Surveillance Camera

Fityanul Akhyar, Ledya Novamizanti, Koredianto Usman, Ghanes Mahesa Aditya, Farhan Nur Hakim and Mukhamad Zidni Ilman (Telkom University, Indonesia); Ferdi Ramdhon (PT. Aruna Jaya Nusantara, Indonesia); Chih-Yang Lin (National Central University, Taiwan)

E5-3 09:40

A UAV Indoor Obstacle Avoidance System Based on Deep Reinforcement Learning

Lee Chung-Nan and Chun-Huang Lo (National Sun Yat-Sen University, Taiwan)

E5-4 10:00

Approximate Modeling of Malware Diffusion on Wireless Mobile Devices

Hideyoshi Miura and Shoya Abukawa (Kansai University, Japan); Tomotaka Kimura (Doshisha University, Japan); Kouji Hirata (Kansai University, Japan)

E5-5 10:20

Impacts of 5G-TDD Time Slot Configurations on the Downlink and Uplink Data Rates

Wen-Ping Lai, Wen-Ru Chen and Hong-Lun Lai (Yuan Ze University, Taiwan)

November 3 (Friday) 09:00-10:40

F5 Recent Advances in Industry 4.0: Exploring New Technologies, Applications, and Best Practices — 201B

Chair: Ming-Hsiang Su (Soochow University, Taiwan) / Sze-Teng Liong (Feng Chia University, Taiwan)

F5-1 09:00

Bearing Fault Diagnosis and Interpretation Based on 2D Images and Convolutional Neural Network

Zhenzhen Tian, Xinyu Zhang, Wei Yan and Jihua Wang (Shandong Normal University, China)

F5-2 09:20

Study on the Reduction of Background Fringes for Detect Detection on Specular Surface

An-Chi Wei (National Central University, Taiwan); Jyh-Rou Sze (Instrument Technology Research Center-NARL, Taiwan); Yi-Cheng Chang (National Central University, Taiwan)

F5-3 09:40

On the Optimal Self-Supervised Multi-Fault Detector for Temperature Sensor Data

Latifa Nabila Harfiya (National Central University, Taiwan); Yan-Cheng Hsu (University of California, San Diego, USA); Yung-Hui Li (AI Research Center, Hon Hai Research Institute, Taiwan); Jia-Ching Wang (National Central University, Taiwan)

F5-4 10:00

Application of Wafer Defect Pattern Classification Model in the Semiconductor Industry

Chin-Wei Lee (Soochow University, Taiwan); Daniel Hladek and Matus Pleva (Technical University of Kosice, Slovakia); Yuan-Fu Liao (National Yang Ming Chiao Tung University, Taiwan); Ming-Hsiang Su (Soochow University, Taiwan)

F5-5 10:20

Question Answering System Based on Pre-Training Model and Retrieval Reranking for Industry 4.0

Ta-Fu Chen and Yi-Xing Lin (National Central University, Taiwan); Ming-Hsiang Su (Soochow University, Taiwan); Po-Kai Chen (National Central University, Taiwan); Tzu-Chiang Tai (Providence University, Taiwan); Jia-Ching Wang (National Central University, Taiwan)

November 3 (Friday) 09:00-10:40

G5 Recent Advances in Intelligent Signal Processing 201C

Chair: Jia-Ching Wang (National Central University, Taiwan) / Chih-Chang Yu (Chung Yuan Christian University, Taiwan)

G5-1 09:00

Deepfake-Speech Detection with Pathological Features and Multilayer Perceptron Neural Network

Anuwat Chaiwongyen (Japan Advanced Institute of Science and Technology, Japan); Suradej Duangpummet and Jessada Karnjana (National Science and Technology Development Agency, Thailand); Waree Kongprawechnon (SIIT, Thailand); Masashi Unoki (Japan Advanced Institute of Science and Technology, Japan)

G5-2 09:20

Temporal and Type Correlation in Digital Phenotyping for Bipolar Disorder State Prediction Using Multitask Self-Supervised Learning

Jia-Hao Hsu, Hua-Wei Tseng, Chung-Hsien Wu, Esther Ching-Lan Lin and Po-See Chen (National Cheng Kung University, Taiwan)

G5-3 09:40

Data Selection Based on Phoneme Affinity Matrix for Electrolarynx Speech Recognition

I-Ting Hsieh and Chung-Hsien Wu (National Cheng Kung University, Taiwan); Shu-Wei Tsai (National Cheng Kung University Hospital, Taiwan)

G5-4 10:00

Reduction of Annotation Effort in Medical Image Analysis Based on Self-Supervised Learning

Kai-Hsuan Chan and Yi-Chong Zeng (Institute for Information Industry, Taiwan)

G5-5 10:20

STUA-Net: A Fingerprint Reconstruction with Swin Transformer and Soft Collective Attention

Farchan Raswa, Prabowo Yoga Wicaksana and Wenny Ramadha Putri (National Central University, Taiwan); Agus Harjoko (Universitas Gadjah Mada, Indonesia); Jia-Ching Wang (National Central University, Taiwan)

H5 Advanced Topics for Automatic Speaker Recognition 201D

Chair: Sayaka Shiota (Tokyo Metropolitan University, Japan) / Naohiro Tawara (NTT Corporation, Japan)

H5-1 09:00

Coarse-Age Loss: A New Training Method Using Coarse-Age Labeled Data for Speaker Age Estimation

Yuki Kitagishi, Hosana Kamiyama, Naohiro Tawara, Atsunori Ogawa, Noboru Miyazaki and Taichi Asami (NTT Corporation, Japan)

November 3 (Friday) 09:00-10:40

H5 Advanced Topics for Automatic Speaker Recognition 201D

Chair: Sayaka Shiota (Tokyo Metropolitan University, Japan) / Naohiro Tawara (NTT Corporation, Japan)

H5-2 09:20

Contribution of Modulation Spectral Features for Cross-Lingual Speech Emotion Recognition Under Noisy Reverberant Conditions

Taiyang Guo, Sixia Li, Shunsuke Kidani, Shogo Okada and Masashi Unoki (Japan Advanced Institute of Science and Technology, Japan)

H5-3 09:40

Vocal Tract Length Perturbation-Based Pseudo-Speaker Augmentation for Speaker Embedding Learning

Tomoka Wakamatsu, Sayaka Shiota and Hitoshi Kiya (Tokyo Metropolitan University, Japan)

H5-4 10:00

Automatic Call Classification of Autism Model Marmosets by Deep Learning and Analysis of Their Vocal Development

Minato Uesaka, Hideto Kawauchi and Kouei Yamaoka (Tokyo Metropolitan University, Japan); Wakabayashi Yukoh (Toyohashi University of Technology, Japan & Tokyo Metropolitan University, Japan); Yuma Kinoshita (Tokai University, Japan); Nobutaka Ono (Tokyo Metropolitan University, Japan); Jun Noguchi, Satoshi Watanabe and Noritaka Ichinohe (National Center of Neurology and Psychiatry, Japan); Seico Benner (National Institute for Environmental Studies & Hamamatsu University School of Medicine, Japan); Hidenori Yamasue (Hamamatsu University School of Medicine, Japan)

H5-5 10:20

Cross-Domain Adaptation in Distance Space for Speaker Verification

Lu Yi and Man-wai Mak (The Hong Kong Polytechnic University, Hong Kong)

I5 AI in Earth and Environment 201E

Chair: Fang-Yi Cheng (National Central University, Taiwan)

I5-1 09:00

Urban Noise Monitoring Using Edge Computing with CNN-LSTM on Jetson Nano

Bo Peng, Waleed H. Abdulla and Kevin I-Kai Wang (The University of Auckland, New Zealand)

I5-2 09:20

Random Forest of Classification and Regression Tree (CART) in the Estimation of SWC Based on Meteorological Inputs and Hydrodynamics Behind

Tsung-Hsi Wu, Pei-Yuan Chen, Chien-Chih Chen, Meng-Ju Chung, Zheng-Kai Ye and Ming-Hsu Li (National Central University, Taiwan)

November 3 (Friday) 09:00-10:40

I5 AI in Earth and Environment 201E

Chair: Fang-Yi Cheng (National Central University, Taiwan)

I5-3 09:40

A Framework for Reusing Earth Science Data on Data and Model Marketplaces

Chung-I Huang, Jih-Sheng Chang, Chen-Kai Sun, Tai-chi Wang and Wei-Yu Chen and Hui Hung Yu (National Center for High-performance Computing, Taiwan); Wen-Yi Chang (High-Performance Computing National Applied Research Laboratories, Taiwan); Fang-Pang Lin (Narlabs, Taiwan)

I5-4 10:00

Impact of the Weighted Loss Function on the Innovative CMAQ-CNN PM2.5 Forecasting Model

Yi-Ju Lee and Fang-Yi Cheng (National Central University, Taiwan); Chih-Yung Feng and Zhih-Min Yang (Manysplendid Infotech, Taiwan)

OS2 Overview Section (II) 201F

Chair: Yuichi Tanaka (Osaka University, Japan)

OS2-1 09:00

Graph Signal Restoration and Graph Estimation/Learning

Yuichi Tanaka (Osaka University, Japan)

OS2-2 09:30

Towards Trustworthy Graph Machine Learning

Cheng-Te Li (National Cheng Kung University, Taiwan)

OS2-3 10:00

Computation of Graph Fourier Transform Centrality of Complex Network Using Graph Filter

Chien-Cheng Tseng (National Kaohsiung University of Science and Technology, Taiwan)

November 1 (Wednesday) 10:20-12:00

P1 Poster Session I

Chair: Yoshiaki Itoh (Iwate Prefectual University, Japan) / Li-Wei Kang (National Taiwan Normal University, Taiwan)

P1-1

Fatigue Classification and Onset Estimation Using Surface EMG Signals During Strength Training

Eswar Adapa (Indian Institute of Information Technology Sri City, India); Anish Turlapaty (Indian Institute of Information Technology, India); Surya Naidu (IIIT Sri City, India)

P1-2

P300 Event-Related Potential in Perception of Multiple Traffic Objects During Vehicle Driving

Yuki Yamamoto (Chubu University, Japan); Sou Nobukawa (Chiba Institute of Technology, Japan); Nobuhiko Wagatsuma (Toho University, Japan); Keiichiro Inagaki (Chubu University, Japan)

P1-3

Kernel Random Projection Depth for Outlier Detection

Akira Tamamori (Aichi Institute of Technology, Japan)

P1-4

Soft-Sensor Construction Method Based on Adaptive Modeling and Transfer Learning for Manufacturing Process Including Maintenance Periods

Kaito Katayama and Koichi Fujiwara (Nagoya University, Japan); Kazuki Yamamoto (AGC Inc., Japan)

P1-5

Detecting Wire Bonding Defects in Point Clouds on Self-Generated Dataset

Shang Li Yuen and Phooi Yee Lau (MIMOS Berhad, Malaysia); Chin Wee Wong (Advanced Intelligence Lab, Malaysia); Muhammad Hafiz Samsuri (MIMOS Berhad, Malaysia); Zarina Hussin (MIMOS Berhad & MIMOS Semiconductor (M) Sdn Bhd, Malaysia); Nur Afiqah Kamarudin and Muhammad Syukri Mohd Talib (MIMOS Berhad, Malaysia); Hock Woon Hon (MIMOS Bhd, Malaysia)

P1-6

Predicting Outcomes of Cognitive Behavioral Therapy for Depression Using Data Driven Approaches

*Lily Tyszczuk (The University of Sheffield & ASTAR, Singapore); Liat Levita (University of Sussex, United Kingdom (Great Britain)); Jaime Delgadillo (The University of Sheffield, United Kingdom (Great Britain)); Haihong Zhang (Institute for Inforcomm Research, A*STAR, Singapore); Mahnaz Arvaneh (The University of Sheffield, United Kingdom (Great Britain))*

P1-7

Learning Adapters for Code-Switching Speech Recognition

Chun-Yi He and Jen-Tzung Chien (National Yang Ming Chiao Tung University, Taiwan)

November 1 (Wednesday) 10:20-12:00

P1 Poster Session I

Chair: Yoshiaki Itoh (Iwate Prefectual University, Japan) / Li-Wei Kang (National Taiwan Normal University, Taiwan)

P1-8

FID-RPRGAN-VC: Fréchet Inception Distance Loss Based Region-Wise Position Normalized Relativistic GAN for Non-Parallel Voice Conversion

Sandipan Dhar and MD Tousin Akhter (NIT Durgapur, India); Padmanabha Banerjee (JGEC, India); Nanda Jana (National Institute of Technology Durgapur, India); Swagatam Das (Indian Statistical Institute, India)

P1-9

Deformable Aligned Fusion for Video Super Resolution

Sin-Hong Lee, Chih-Hung Kuo and Tsai Chun Yu (National Cheng Kung University, Taiwan)

P1-10

Learning Single Image Rain Streak Removal Based on Deep Attention Mechanism

Kuan-Hua Huang and Li-Wei Kang (National Taiwan Normal University, Taiwan)

P1-11

A Transformer-Based Framework for Tiny Object Detection

Yi-Kai Liao, Gong-Si Lin and Mei-Chen Yeh (National Taiwan Normal University, Taiwan)

P1-12

Lightweight Models Distillation with Learnable Teaching Material: An Application for Smart Table Tennis System

Duan-Yu Chen (Department of Electrical Engineering, Yuan Ze University, Taiwan); Yu-Hsuan Chen (Yuan Ze University, Taiwan)

P1-13

Selecting Suitable Data Input for Deep-Learning Sign-Language Recognition with a Small Dataset

Yu-Jen Chen and Po-Chyi Su (National Central University, Taiwan)

P1-14

Analysis of the Interaction Effect on Pruning and Transfer Learning in Model Training

Yu-Jen Wei, Jia-Hong Chen and Tien-Ying Kuo (National Taipei University of Technology, Taiwan)

P1-15

Old Damaged Photo Recovery with Style Transfer-Based Data Augmentation

Chih-Hao Wang, Yu-Jen Wei, Ching Hsiang Chang and Tien-Ying Kuo (National Taipei University of Technology, Taiwan)

November 1 (Wednesday) 10:20-12:00

P1 Poster Session I

Chair: Yoshiaki Itoh (Iwate Prefectual University, Japan) / Li-Wei Kang (National Taiwan Normal University, Taiwan)

P1-16

A Deep Learning Based Sustainable Energy Scheduling System

Kun-Lin Tsai (TungHai University, Taiwan); Yan-Hao Chen, Choa-Ting Huang, Guo-Wei Huang and Shih-Ting Tseng (Tunghai University, Taiwan)

P1-17

A Computational Efficient Direct Position Determination Approach of Narrow-Band Emitter

Yuan Zhao (Shenzhen Institute of Artificial Intelligence and Robotics for Society); Hanmin Sheng and Jinliang Shao (University of Electronic Science and Technology of China, China)

P1-18

Modeling and Analysis of the Epidemic-Behavior Co-Evolution Dynamics with User Irrationality

Wenxiang Dong and H. Vicky Zhao (Tsinghua University, China)

P1-19

Noise-Robust Pitch Detection Based on Super-Resolution Harmonics

Dongjie Zhu (Institute of Information Science, Beijing Jiaotong University); Tianrui Wang and Weibin Zhu (Institute of Information Science, Beijing Jiaotong University, China); Yingying Gao, Junlan Feng and ShiLei Zhang (China Mobile Research Institute, China)

P1-20

A Subband Approach to Personal Sound Zone with Joint Optimization of Sound Pressure and Particle Velocity

Yingke Zhao (Shaanxi University of Science and Technology, China); Wen Zhang (Northwestern Polytechnical University, China); Jingdong Chen (Center of Intelligent Acoustics and Immersive Communications, China)

P1-21

An Multi-Evidence Fusion Based on C-Distance with Uncertain Reasoning for Classification

Cuiping Cheng (ZHEJIANG LAB, China); Pengcheng Yue and Taihao Li (Zhejiang Lab, China)

P1-22

On Uncertainty Principles for Lowband Graph Signals

Na Li, Linbo Shang and Zhichao Zhang (Nanjing University of Information Science and Technology, China)

P1-23

CoA-DLinkNet: Connectivity-Enhanced Dual-Branch Road Extraction Network Based on D-LinkNet

Linghan Li, Heliu Chen, Renjie He, Yuchao Dai and Mingyi He (Northwestern Polytechnical University, China)

November 1 (Wednesday) 10:20-12:00

P1 Poster Session I

Chair: Yoshiaki Itoh (Iwate Prefectual University, Japan) / Li-Wei Kang (National Taiwan Normal University, Taiwan)

P1-24

Black-Box Lossless Fragile Watermarking Based on Hidden Space Search for DNN Integrity Authentication

Gejian Zhao and Chuan Qin (University of Shanghai for Science and Technology, China)

P1-25

Hiding Patient Information in Medical Images: A High-Capacity and Reversible Hiding Algorithm for E-Healthcare

Xiaoyi Zhou and Shuai Lee (Hainan University, China)

P1-26

A Visually Meaningful Image Encryption Algorithm with Attention Mechanism and Artificial Bee Colony Optimization

Jiarong Mao, Yuting An and Xiaoyi Zhou (Hainan University, China)

P1-27

High-Quality Triggers Based Fragile Watermarking for Optical Character Recognition Model

Yujie Yin and Heng Yin (Anhui University, China); Zhaoxia Yin (East China Normal University, China); Wanli Lyu (Anhui University, China); Sha Wei (China Academy of Information and Communication Technology, China)

P1-28

Coupled Transformed Induced Tensor Nuclear Norm for Robust Tensor Completion

Mengjie Qin (Zhejiang Lab & Research Center for Intelligent Robotics, Research Institute of Interdisciplinary Innovation, China); Zheyuan Lin, Minhong Wan and Chunlong Zhang (Zhejiang Lab, China); Jason Gu (Dalhousie University, Canada); Te Li (Zhejiang Lab, China)

P1-29

Multi-Frequency Feature Enhancement for Multi-Granularity Visual Classification

Meijiang Fu, Yixiao Zheng, Dongliang Chang and Wenpan Li (Beijing University of Posts and Telecommunications, China); Zhanyu Ma (BUPT-Beijing University of Posts and Telecommunications, China)

P1-30

Improving Aspect Sentiment Classification via Retrieving from Training Data

Tongtao Ling and Lei Chen (Guangdong University of Technology, China); Chen Liao and Shilei Huang (Shenzhen Raisound Technologies, China); Zhipeng Yu (Guangdong University of Technology, China); Liu Yi (Shenzhen Key Laboratory of Intelligent Media and Speech, PKU-HKUST Institution, China)

November 1 (Wednesday) 15:00-17:00

P2 Poster Session II

Chair: Tien-Ying Kuo (National Taipei University of Technology, Taiwan) / Jen-Tzung Chien (National Yang Ming Chiao Tung University, Taiwan)

P2-1

Segmentation Enhancement for Iris Recognition Using Unit Gradient Vectors

Limhourlaurent Meam (Sirindhorn International Institute of Technology, Thammasat University, Thailand); Suradej Duangpummet (National Science and Technology Development Agency, Thailand); Waree Kongprawechnon (SIIT, Thailand)

P2-2

FactLLaMA: Optimizing Instruction-Following Language Models with External Knowledge for Automated Fact-Checking

Tsun-Hin Cheung (The Hong Kong Polytechnic University, Hong Kong); Kin-Man Lam (Hong Kong Polytechnic University, Hong Kong)

P2-3

Auditory Representation Effective for Estimating Vocal Tract Information

Toshio Irino and Shintaro Doan (Wakayama University, Japan)

P2-4

Accurate and Practical Query-By-Example by Using Multiple Deep Learning Models and Frame Compression Methods

Hikaru Yamaga and Yoshiaki Itoh (Iwate Prefectural University, Japan)

P2-5

Fundamental Frequency Estimation Based on Finite-Order Harmonic Constraint Differential Equation

Kenta Yamada, Yoshiki Masuyama, Kouei Yamaoka and Nobutaka Ono (Tokyo Metropolitan University, Japan)

P2-6

Tone Labeling by Deep Learning-Based Tone Recognizer for Mandarin Speech

WuHao Li and Chen Yu Chiang (National Taipei University, Taiwan); TehSin Liu (National Taiwan University, Taiwan)

P2-7

Learning to Enhance the Position Embedding and Coherence

Ting-Jia Shu and Jen-Tzung Chien (National Yang Ming Chiao Tung University, Taiwan)

P2-8

VLSI Design of Lossless Image Compression Using Improved LZW

Yao-Zhong Zhang, Chiung-An Chen and Jia Wen Wang (Ming Chi University of Technology, Taiwan)

November 1 (Wednesday) 15:00-17:00

P2 Poster Session II

Chair: Tien-Ying Kuo (National Taipei University of Technology, Taiwan) / Jen-Tzung Chien (National Yang Ming Chiao Tung University, Taiwan)

P2-9

The Color Demosaicing and Image Scaling Based on Improve Hamilton-Adams

Yu-Wen Peng, Chia-Yu Hu, Yen-Ju Chin and He-Sheng Chou (Chung Yuan Christian University, Taiwan); Yuan-Jin Lin (National Cheng Kung University, Taiwan); Yu-Lin Liu and Shih-Lun Chen (Chung Yuan Christian University, Taiwan)

P2-10

Improving Regularization of Deep Learning Models in Fundus Analysis

Wei-Wen Hsu (National Taitung University, Taiwan); Yao-Chung Chang (Natioal Taitung University, Taiwan); Wei-Min Lee (National Taitung University, Taiwan); Yu-Chuan Huang (National Defense Medical Center, Taiwan); Da-Wen Lu (Tri-Service General Hospital and National Defense Medical Center, Taiwan)

P2-11

Design of Interactive System for Acupoint Analysis Based on Augmented Reality

Chung-Yen Wei, Yu-Xaing Zhao and Bo-yuan Xu (National Quemoy University, Taiwan)

P2-12

Anomaly Detection of Rolling Element Bearings Using Domain Adaptation

Hsin-Tse Lu (National Chengchi University)

P2-13

Dental Positioning Medical Assistance System for BiteWing Radiograph Based on YOLOV4 and Image Enhancement

Li Yi-Qian, Mu-Feng Lin, Tsung-Yi Chen and Yu-Lin Liu (Chung Yuan Christian University, Taiwan); Yuan-Jin Lin (National Cheng Kung University, Taiwan); Mei-Ling Chan (Jiaying University, China); Chiung-An Chen (Ming Chi University of Technology, Taiwan); Li Kuo-Chen (Chung Yuan Christian University, Taiwan); Li Chun-Wei (Chang Gung Memorial Hospital, Taiwan); Shih-Lun Chen (Chung Yuan Christian University, Taiwan)

P2-14

Asynchronous Federated Learning Method in the 6G Massive Multimedia Transmission System

Yen-Ching Chang, Sheng-Siang Liao and Chin-Feng Lai (National Cheng Kung University, Taiwan)

P2-15

The Development of an AI-Assisted Diagnosis System for Adult Glioma Subtyping Prediction

Wei-Wen Hsu (National Taitung University, Taiwan); Jia-Yi Lin and Hsin-Hung Lai (National Defense Medical Center, Taiwan); Wan-Lin Hsu and Jeng-Ting Jiang (National Taitung University, Taiwan); Yao-Chung Chang (Natioal Taitung University, Taiwan); YaoFeng Li (Tri-Service General Hospital and National Defense Medical Center, Taiwan)

November 1 (Wednesday) 15:00-17:00

P2 Poster Session II

Chair: Tien-Ying Kuo (National Taipei University of Technology, Taiwan) / Jen-Tzung Chien (National Yang Ming Chiao Tung University, Taiwan)

P2-16

Poisoning Attacks Against Gait-Based Identity Recognition

Jianmin Dong (Zhejiang lab, China); Da-tian Peng (Northwestern Polytechnical University, China); Guanxiong Pei and Taihao Li (Zhejiang Lab, China)

P2-17

STrack: Velocity Estimation Using Single Antenna WiFi Devices

Jian Xu, Dongheng Zhang, Jiamu Li, Qibin Sun and Yan Chen (University of Science and Technology of China, China)

P2-18

SEformer: Dual-Path Conformer Neural Network is a Good Speech Denoiser

Kai Wang and Dimitrios Hatzinakos (University of Toronto, Canada)

P2-19

Complex Feature Information Enhanced Speech Emotion Recognition

Pengcheng Yue, Shukai Zheng and Taihao Li (Zhejiang Lab, China)

P2-20

Incorporating Pinyin into Pipeline Named Entity Recognition from Chinese Speech

Min Zhang, Xiaosong Qiao and Yanqing Zhao (Huawei co. LTD, China); Shimin Tao and Hao Yang (Huawei, China)

P2-21

Learning Semantic Information from Machine Translation to Improve Speech-To-Text Translation

Pan Deng and Jie Zhang (University of Science and Technology of China, China); Xinyuan Zhou and Zhongyi Ye (iFlytek Research, China); Weitai Zhang, Jianwei Cui and Li-Rong Dai (University of Science and Technology of China, China)

P2-22

Effective Fine-Tuning Method for Tibetan Low-Resource Dialect Speech Recognition

Yang Jiahao and Jianguo Wei (Tianjin University, China); Kuntharrgyal Khysru Kuntharrgyal Khysru (Qinghai Minzu University, Xining, China); Xu Junhai, Lu Wenhuan, Wenjun Ke and Xiaokang Yang (Tianjin University, China)

P2-23

Multi-Task Piano Transcription with Local Relative Time Attention

Qi Wang, Mingkuan Liu, Xianhong Chen and Wenmeng Xiong (Beijing University of Technology, China)

November 1 (Wednesday) 15:00-17:00

P2 Poster Session II

Chair: Tien-Ying Kuo (National Taipei University of Technology, Taiwan) / Jen-Tzung Chien (National Yang Ming Chiao Tung University, Taiwan)

P2-24

Real and Imaginary Part Interaction Network for Monaural Speech Enhancement and De-Reverberation

Zehua Zhang (Harbin Institute of TechnologyHarbin Institute of Technology, Shenzhen, China); Changjun He and Shiyun Xu (Harbin Institute of Technology, Shenzhen, China); Wang Ming-Jiang (Harbin Institute of Technology, China)

P2-25

Progressive Multi-Scale Self-Supervised Learning for Speech Recognition

Hang Chen and Genshun Wan (University of Science and Technology of China, China); Tan Liu (iFLYTEK Research, iFLYTEK Co. Ltd., China); Chenxi Wang (University of Science and Technology of China, China); Pan Jia (iFlytek, China); Zhongfu Ye (University of Science & Technology of China, China)

P2-26

Improved Data2vec with Soft Supervised Hidden Unit for Mandarin Speech Recognition

Genshun Wan and Hang Chen (University of Science and Technology of China, China); Pengcheng Li (iFLYTEK Research, iFLYTEK Co. Ltd., China); Pan Jia (iFlytek, China); Zhongfu Ye (University of Science & Technology of China, China)

P2-27

Investigation of Ensemble of Self-Supervised Models for Speech Emotion Recognition

Yanfeng Wu and Pengcheng Yue (Zhejiang Lab, China); Cuiping Cheng (ZHEJIANG LAB, China); Taihao Li (Zhejiang Lab, China)

P2-28

Single Source Zone Detection in the Spherical Harmonic Domain for Multisource Localization

Liang Tao, Maoshen Jia and Bing Bu (Beijing University of Technology, China); Dingding Yao (Chinese Academy of Sciences, China)

P2-29

Robust Representation Learning for Speech Emotion Recognition with Moment Exchange

Yunrui Cai and Changhe Song (Tsinghua University, China); Boshi Tang (Tsinghua University & Shenzhen International Graduate School, China); Dongyang Dai (THU, China); Zhiyong Wu (Graduate School at Shenzhen, Tsinghua University, China); Helen Meng (Chinese University of Hong Kong, Hong Kong)

P2-30

Few Shot Learning Guided by Emotion Distance for Cross-Corpus Speech Emotion Recognition

Pengcheng Yue, Yanfeng Wu, Leyuan Qu, Shukai Zheng, Shuyuan Zhao and Taihao Li (Zhejiang Lab, China)

November 2 (Thursday) 09:00-10:40

P3 Poster Session III

Chair: Ryo Matsuoka (The University of Kitakyushu, Japan) / Chung-Nan Lee (National Sun Yat-sen University, Taiwan)

P3-1

Remarks on an Optimal Predictive Control Using a Quaternion Neural Network and a Metaheuristics Optimisation Method

Kazuhiko Takahashi, Remi Aoki, Eri Kagamiishi and Masafumi Hashimoto (Doshisha University, Japan)

P3-2

Classification of Normal vs. Pathological Infant Cries Using Morse Wavelets

Priyanka Gupta, Aastha Kachhi and Hemant A. Patil (Dhirubhai Ambani Institute of Information and Communication Technology, India)

P3-3

Compressive Sensing Based Algorithms for Limited-View PAT Image Reconstruction

Mary Anjaley Josy John (UAE University, United Arab Emirates); Imad Barhumi (United Arab Emirates University, United Arab Emirates)

P3-4

Towards AST-LLDs for the Analysis of Depression in Speech Signals

Sidharrth Nagappan and Chern Hong Lim (Monash University, Malaysia); Anuja T Dharmaratne (Monash University Australia, Australia)

P3-5

ecVoice: Audio Text Extraction Optimization of Video Based on Idioms Similarity Replacement

Jinwei Lin (Monash University, Malaysia)

P3-6

Heart Rate Acquisition and Processing Techniques for a Miniature Wearable Microphone Sensor

Yi Yang Ang (Aevice Health Pte Ltd, Singapore & Nanyang Technological University, Singapore); Kirish Boodhoo (Aevice Health Ptd Ltd, Singapore); Wee Ser and Rex Xiao Tan (Aevice Health Pte Ltd, Singapore)

P3-7

A Study on Counter-Movement Detection on Dumbbell Curl Using Convolutional Autoencoder

Atsuya Emoto (The University of Kitakyushu, Japan); Koh Inoue (Kagawa University, Japan); Ryo Matsuoka (The University of Kitakyushu, Japan)

P3-8

Causal Analysis of Hepatic Fat Accumulation by Linear Mixed Causal Model

Takashi Nojima (Kyoto University, Japan); Yoshito Itoh, Kota Yano, Kanji Yamaguchi, Yuya Seko and Satoaki Matoba (Kyoto Prefectural University of Medicine, Japan); Kenichi Nishioji (Japanese Red Cross Kyoto Daini Hospital, Japan); Koichi Fujiwara (Nagoya University, Japan); Shota Kato and Manabu Kano (Kyoto University, Japan)

November 2 (Thursday) 09:00-10:40

P3 Poster Session III

Chair: Ryo Matsuoka (The University of Kitakyushu, Japan) / Chung-Nan Lee (National Sun Yat-sen University, Taiwan)

P3-9

Investigation of the Neuromodulation Effect of tVNS on Electrical Brain Activity

WooJin Kim, Yun-Sung Lee and Hyuk Choi (Korea University, Korea (South)); Jae-Jun Song (Korea University Guro Hospital, Korea (South)); Ki-Hwan Hong (Neurive Coporation, Korea (South)); Han-Jeong Hwang (Korea University, Korea (South))

P3-10

Gender-Specific EEG Feature-Based Diagnostic Tool for Male Depression Based on Machine-Learning Techniques

EunGyoung Yi and Miseon Shim (Korea University, Korea (South)); Seung-Hwan Lee (Ilsan Paik Hospital, Inje University, Korea (South)); Han-Jeong Hwang (Korea University, Korea (South))

P3-11

Optimal Input Data Search of Deep Learning Model for Cognitive Task Classification Based on NIRS

Ahyun Kim, Hyung-Tak Lee and Han-Jeong Hwang (Korea University, Korea (South))

P3-12

Detection and Correction of Defective Relative Humidity Data Collected from the Greenhouse Environment Using Nested Kalman Filters with Standard Deviation Analysis

Kraithep Sirisanwannakul and Nutchanon Siripool (Thammasat University, Thailand); Kenji Suzuki (Tokyo Institute of Technology, Japan); Waree Kongprawechnon (SIIT, Thailand); Jessada Karnjana (National Science and Technology Development Agency, Thailand)

P3-13

Pedestrian Crossing Intention Prediction with Multi-Modal Transformer-Based Model

Ting Wei Wang and Shang-Hong Lai (National Tsing Hua University, Taiwan)

P3-14

Revolutionizing Formative Assessment in STEM Fields: Leveraging AI and NLP Techniques

Chi Wee Tan, Ts. (Faculty of Computing and Information Technology, Tunku Abdul Rahman University of Management and Technology, 53300 Setap); Khai Yin Lim (Department of Computing and Information Technology, Tunku Abdul Rahman University of Management and Technology, Penang,)

P3-15

A Biased Mixed-Precision Convolution Engine for Hardware-Efficient Computational Imaging CNN

Hao-Jiun Tu and Yu-Feng Ou (National Tsing Hua University, Taiwan); Yong-Tai Chen (NTHU, Taiwan); Huang Chao-Tsung (National Tsing Hua University, Taiwan)

November 2 (Thursday) 09:00-10:40

P3 Poster Session III

Chair: Ryo Matsuoka (The University of Kitakyushu, Japan) / Chung-Nan Lee (National Sun Yat-sen University, Taiwan)

P3-16

A Lightweight Speaker Verification Model for Edge Device

Ting-Wei Chen (National Sun Yat-sen University, Taiwan); Chia-Ping Chen (National Sun Yat-Sen University, Taiwan); Chung-Li Lu, Bo-Cheng Chan, Yu-Han Cheng, Hsiang-Feng Chuang and Wei-Yu Chen (Chunghwa Telecom Laboratories, Taiwan)

P3-17

Efficient Dictionary and Grid-Based Framework for Answering Durable k-Nearest Neighbor Queries on Time Series Data

Bagus Jati Santoso, Dwi Prasetya Armunanta, Baskoro Adi Pratomo and Hudan Studiawan (Institut Teknologi Sepuluh Nopember, Indonesia)

P3-18

Dual-Path Residual Attention Convolution Networks for Color-Embedded-Grayscale Image

Heri Prasetyo, Abid Ammar Mahdy, Abrar Dwi Fairuz Nadhif, Taufiqurrakhman Nur Hidayat and Rudi Hartono (Universitas Sebelas Maret, Indonesia)

P3-19

DOC: A Novel DOuble-Contour-Based Macro Placement Framework for Mixed-Size Designs

Yin-Rong Zhuo, Hui-Lin Chen and Yu-Guang Chen (National Central University, Taiwan)

P3-20

Hindering Adversarial Attacks with Multiple Encrypted Patch Embeddings

AprilPyone MaungMaung and Isao Echizen (National Institute of Informatics (NII), Japan); Hitoshi Kiya (Tokyo Metropolitan University, Japan)

P3-21

Implementation of PLIM on 429MHz LoRa/FSK with Improved Conversion Table

Keita Takeda, Ryuji Miyamoto and Osamu Takyu (Shinshu University, Japan)

P3-22

Numerical Performance Evaluation of Sparse Reconstruction Using Optical Analog Circuit

Soma Furusawa and Kazunori Hayashi (Kyoto University, Japan); Kaito Kameda and Ryo Hayakawa (Osaka University, Japan)

P3-23

Assessing the Effects of Filtering Processing on Pulse Wave Transit Time Measured by Photoplethysmography from Earlobe

Shangdi Liao and Fei Chen (Southern University of Science and Technology, China)

November 2 (Thursday) 09:00-10:40

P3 Poster Session III

Chair: Ryo Matsuoka (The University of Kitakyushu, Japan) / Chung-Nan Lee (National Sun Yat-sen University, Taiwan)

P3-24

Efficient Incremental Text-To-Speech on GPUs

Muyang Du, Chuan Liu, Jiaxing Qi and Junjie Lai (NVIDIA Corporation, China)

P3-25

Retinex-Based Low-Light Image Enhancement

Rui Luo and Yan Feng (Northwestern Polytechnical University, China)

P3-26

Fine-Grained Face Anti-Spoofing Based on Recursive Self-Attention and Multi-Scale Fusion

Shichuang Xie, Jiasheng Wu and Yanli Chen (Hangzhou Dianzi University, China); Meng Han (Zhejiang University, China); Ting Wu (Beihang University, China); Tong Qiao (Hangzhou Dianzi University, China)

P3-27

StyleStegan: Leak-Free Style Transfer Based on Feature Steganography

Xiujian Liang (Fudan University, China); Bingshan Liu (Nanjing University of Information Science & Technology, China); Qichao Ying, Zhenxing Qian and Xinpeng Zhang (Fudan University, China)

P3-28

Robust Watermark Imaging via Graph-Signal Optimization

Ruiguo Yang, Xinhui Han, Wenfa Qi and Wei Hu (Peking University, China)

P3-29

A Print-Scan-Resilient Watermarking Scheme for Trademark Images

Wenfa Qi (Peking University, China); Jiameng Wang and Zichen Yuan (Beijing Jiaotong Universitgy, China); Xiaolong Li (Beijing Jiaotong University, China)

P3-30

AI-Generated Image Detection Using a Cross-Attention Enhanced Dual-Stream Network

Ziyi Xi, Wenmin Huang, Kangkang Wei, Weiqi Luo and Peijia Zheng (Sun Yat-Sen University, China)

November 2 (Thursday) 13:30-15:30

P4 Poster Session IV

Chair: Yoichi Haneda (The University of Electro-Communications, Japan) / Chih-Hsien Hsia (National Ilan University, Taiwan)

P4-1

Word Encoding for Word-Looking DGA-Based Botnet Classification

Sea Ran Cleon Liew (University of Waterloo, Canada); Ngai Fong Law (Hong Kong Polytechnic University, Hong Kong)

P4-2

Analysis of Spectro-Temporal Modulation Representation for Deep-Fake Speech Detection

Haowei Cheng, Candy Olivia Mawalim, Kai Li, Lijun Wang and Masashi Unoki (Japan Advanced Institute of Science and Technology, Japan)

P4-3

Flexible Evidence Model to Reduce Uncertainty Mismatch Between Speech Enhancement and ASR Based on Encoder-Decoder Architecture

Ryu Takeda (Osaka University, Japan); Yui Sudo (Honda Research Institute Japan, Japan); Kazunori Komatani (Osaka University, Japan)

P4-4

Investigating the Effectiveness of Speaker Embeddings for Shout Intensity Prediction

Takahiro Fukumori, Taito Ishida and Yoichi Yamashita (Ritsumeikan University, Japan)

P4-5

Is the Ideal Ratio Mask Really the Best? Exploring the Best Extraction Performance and Optimal Mask of Mask-Based Beamformers

Atsuo Hiroe, Katsutoshi Itoyama and Kazuhiro Nakadai (Tokyo Institute of Technology, Japan)

P4-6

Language Modeling for Spontaneous Speech Recognition Based on Disfluency Labeling and Generation of Disfluent Text

Koharu Horii (Toyohashi University of Technology, Japan); Kengo Ohta (National Institute of Technology, Anan College, Japan); Ryota Nishimura (Tokushima University, Japan); Atsunori Ogawa (NTT Corporation, Japan); Norihide Kitaoka (Toyohashi University of Technology, Japan)

P4-7

Transformer-Based Automatic Speech Recognition of Simultaneous Interpretation with Auxiliary Input of Source Language Text

Shuta Taniguchi, Tsuneo Kato and Akihiro Tamura (Doshisha University, Japan); Yasuda Keiji (MINDWORD, Inc., Japan)

November 2 (Thursday) 13:30-15:30

P4 Poster Session IV

Chair: Yoichi Haneda (The University of Electro-Communications, Japan) / Chih-Hsien Hsia (National Ilan University, Taiwan)

P4-8

An Analysis of Personalized Speech Recognition System Development for the Deaf and Hard-Of-Hearing

Lester Phillip G Violeta and Tomoki Toda (Nagoya University, Japan)

P4-9

Classification of Vocal Cord Disorders: Comparison Across Voice Datasets, Speech Tasks, and Machine Learning Methods

Ching-Chieh Chen (National Tsing Hua University, Taiwan); Wei-Cheng Hsu (China Medical University Hospital, Taiwan); Tzu-Han Lin and Kuan-Dar Chen (National Tsing Hua University, Taiwan); Yung-An Tsou (China Medical University Hospital, Taiwan); Yi-Wen Liu (National Tsing Hua University, Taiwan)

P4-10

Detecting the Underwater Distance and Swimming Direction of Tilapia Using YOLO

Yi-Zeng Hsieh, Chia-Hsuan Wu and Cheng-Hou Chou (National Taiwan University of Science and Technology, Taiwan)

P4-11

Application of Deep Learning Techniques for Thermal Imagery Analysis in Abnormal Identification of Floor Tiles in Heritage Environments

Xin-Yu Chen, Pei-Chen Wu, Li Kuo-Chen, Chu Yu-Chieh, Tsung-Yi Chen and Yu-Lin Liu (Chung Yuan Christian University, Taiwan); Yuan-Jin Lin (National Cheng Kung University, Taiwan); Chiung-An Chen (Ming Chi University of Technology, Taiwan); Mei-Ling Chan (Jiaying University, China); Huang Ching-Hui and Shih-Lun Chen (Chung Yuan Christian University, Taiwan)

P4-12

Wavelet and Cutout in YOLO Architecture for Road Pothole Detection

Chih-Hsien Hsia (National Ilan University, Taiwan)

P4-13

Robust Finger Vein Recognition Based on Lightweight Attention Convolutional Neural Networks

Chih-Hsien Hsia (National Ilan University, Taiwan)

P4-14

Lightweight CNN and Image Enhancement Using in Palm Vein Recognition

Chih-Hsien Hsia (National Ilan University, Taiwan)

November 2 (Thursday) 13:30-15:30

P4 Poster Session IV

Chair: Yoichi Haneda (The University of Electro-Communications, Japan) / Chih-Hsien Hsia (National Ilan University, Taiwan)

P4-15

Breast Cancer Detection Auxiliary System Leveraging Deep Learning and Mixed Reality

Szu-Yin Lin, Ming-Chun Chien, Edwin Tiong Kwong Meng, Yu-Chieh Wang, Yu-Yi Kuo and Che-Hsuan Lin (National Ilan University, Taiwan)

P4-16

Efficient Reversible Data Hiding for 3D Mesh Models Based on Multi-LSB Substitution and Ring-Prediction

Wanli Lyu and Lulu Cheng (Anhui University, China); Zhaoxia Yin (East China Normal University, China); Bin Luo (Anhui University, China)

P4-17

MAEDefense: An Effective Masked AutoEncoder Defense Against Adversarial Attacks

Mengjiang Wu and Wanli Lyu (Anhui University, China); Zhaoxia Yin (East China Normal University, China); Bin Luo (Anhui University, China)

P4-18

Preemptive Image Protection Against Steganography

Yusheng Guo, Nan Zhong, Zhenxing Qian and Xinpeng Zhang (Fudan University, China)

P4-19

Zero-Shot Multi-Speaker Accent TTS with Limited Accent Data

Mingyang Zhang (The Chinese University of Hong Kong, Shenzhen, China); Yi Zhou (National University of Singapore, Singapore); Zhizheng Wu and Haizhou Li (The Chinese University of Hong Kong Shenzhen, China)

P4-20

Speech Enhancement with Multi-Granularity Vector Quantization

Xiaoying Zhao, Qiushi Zhu and Jie Zhang (University of Science and Technology of China, China); Yeping Zhou and Peiqi Liu (China Merchants Bank, China)

P4-21

A Comparative Study on Multichannel Speaker-Attributed Automatic Speech Recognition in Multi-Party Meetings

Mohan Shi and Jie Zhang (University of Science and Technology of China, China); Zhihao Du, Fan Yu, Qian Chen and Shiliang Zhang (Alibaba Group, China); Li-Rong Dai (University of Science and Technology of China, China)

P4-22

Hybrid Syllable and Character Representations for Mandarin ASR

Fengrun Zhang and Chengfei Li (TAL Education Group, China)

November 2 (Thursday) 13:30-15:30

P4 Poster Session IV

Chair: Yoichi Haneda (The University of Electro-Communications, Japan) / Chih-Hsien Hsia (National Ilan University, Taiwan)

P4-23

Enhancing Whisper Model for Pronunciation Assessment with Multi-Adapters

Jing Li (Xinjiang University, China); Rui Li and Shen Guo (XinJiang University, China); Aishan Wumaier (Xinjiang University, China)

P4-24

DoA Estimation of Room Reflections Using NN-Based MUSIC Algorithm

Haowen Li (Northwestern Polytechnical University, Xi'an, China); Wen Zhang and Lijun Zhang (Northwestern Polytechnical University, China)

P4-25

Hybrid Multi-Task Learning for End-To-End Multimodal Emotion Recognition

Junjie Chen (Tianjin Normal University, China); Yongwei Li (CASIA, China); Ziping Zhao (Tianjin Normal University, China); Xuefei Liu (CASIA, China); Zhengqi Wen (Institute of Automation, Chinese Academy of Sciences, China); Jianhua Tao (Tsinghua University, China)

P4-26

It's What You Say and How You Say It: Exploring Audio and Textual Features for Podcast Data

Neil Shah (TCS Research); Vivek Srivastava, Mohit Bhardwaj and Satej Kadlay (TCS Research, India); Dharmeshkumar Agrawal (Dhirubhai Ambani Institute of Information and Communication Technology, India); Savita Bhat (Tata Research Development and Design Centre, India); Niranjan Pedanekar (Tata Research Development and Design Centre & Tata Consultancy Services Limited, India)

P4-27

Improved One-Class Learning for Voice Spoofing Detection

Lixiang Li, Xiaopeng Xue, Haipeng Peng, Yeqing Ren and Mengmeng Zhao (Beijing University of Posts and Telecommunications, China)

P4-28

Sound Field Estimation Around a Rigid Sphere with Physics-Informed Neural Network

Xingyu Chen and Fei Ma (Australian National University, Australia)

P4-29

A Controlled Noise Reduction Wiener Filter Based on the Quadratic Eigenvalue Problem

Ningning Pan (Southwestern University of Finance and Economics, China); Jacob Benesty (INRS-EMT, University of Quebec, Canada); Jingdong Chen (Center of Intelligent Acoustics and Immersive Communications, China)

P4-30

Target Speaker Extraction with Attention Enhancement and Gated Fusion Mechanism

Sijie Wang (Xinjiang University, China); Askar Hamdulla (Xinjiang University of China, China); Ablimit Mijit (Xinjiang University, China)

November 3 (Friday) 09:00-10:40

P5 Poster Session V

Chair: Toshio Irino (Wakayama University, Japan) / Yi-Zeng Hsieh (National Taiwan University of Science and Technology, Taiwan)

P5-1

Jointly Modelling Transcriptions and Phonemes with Optimal Features to Detect Dementia from Spontaneous Cantonese

Xiaoquan Ke (The Hong Kong Polytechnic University, Hong Kong); Man Wai Mak (Hong Kong Polytechnic University, Hong Kong); Helen Meng (Chinese University of Hong Kong, Hong Kong)

P5-2

Combining Multiple End-To-End Speech Recognition Models Based on Density Ratio Approach

Keigo Hojo (University of Technology, Japan); Daiki Mori (Toyohashi University of Technology, Japan); Wakabayashi Yukoh (Toyohashi University of Technology, Japan & Tokyo Metropolitan University, Japan); Kengo Ohta (National Institute of Technology, Anan College, Japan); Atsunori Ogawa (NTT Corporation, Japan); Norihide Kitaoka (Toyohashi University of Technology, Japan)

P5-3

Speech-Emotion Control for Text-To-Speech in Spoken Dialogue Systems Using Voice Conversion and x-Vector Embedding

Shunichi Kohara, Masanobu Abe and Sunao Hara (Okayama University, Japan)

P5-4

Narrow-Edged Acoustical Beamforming Utilizing Phase Inversion for Frequency Modulation-Based Parametric Array Loudspeaker

Yuting Geng (Ritsumeikan University, Japan); Masato Nakayama (Osaka Sangyo University, Japan); Takanobu Nishiura (Ritsumeikan University, Japan)

P5-5

Corpus Construction for Deaf Speakers and Analysis by Automatic Speech Recognition

Akio Kobayashi (Yamato University, Japan); Keiichi Yasu (Tsukuba University of Technology, Japan)

P5-6

Ensemble of Transformer and Convolutional Recurrent Neural Network for Improving Discrimination Accuracy in Automatic Chord Recognition

Hikaru Yamaga and Yoshiaki Itoh (Iwate Prefectural University, Japan)

P5-7

Construction of Automatic Speech Recognition Model That Recognizes Linguistic Information and Verbal/Non-Verbal Phenomena

Nagito Shione and Norihide Kitaoka (Toyohashi University of Technology, Japan); Wakabayashi Yukoh (Toyohashi University of Technology, Japan & Tokyo Metropolitan University, Japan)

November 3 (Friday) 09:00-10:40

P5 Poster Session V

Chair: Toshio Irino (Wakayama University, Japan) / Yi-Zeng Hsieh (National Taiwan University of Science and Technology, Taiwan)

P5-8

Exploring Isolated Musical Notes as Pre-Training Data for Predominant Instrument Recognition in Polyphonic Music

Lifan Zhong (The University of Tokyo, Japan); Erica Cooper and Junichi Yamagishi (National Institute of Informatics, Japan); Nobuaki Minematsu (The University of Tokyo, Japan)

P5-9

Speech Quality Improvement Utilizing Out-Of-Focus Areas in Rolling-Shutter Video on Speech Extraction

Hayata Nakano, Tsubasa Yoshizawa, Yuting Geng, Kenta Iwai and Takanobu Nishiura (Ritsumeikan University, Japan)

P5-10

Personalized Audio Quality Preference Prediction

Chung-Che Wang, Yu-Chun Lin and Yu-Teng Hsu (National Taiwan University, Taiwan); Jyh-Shing Jang (NTU, Taiwan)

P5-11

AVATAR: Robust Voice Search Engine Leveraging Autoregressive Document Retrieval and Contrastive Learning

Yi-Cheng Wang, Tzu-Ting Yang, Hsin-Wei Wang, Bi-Cheng Yan and Berlin Chen (National Taiwan Normal University, Taiwan)

P5-12

Regression-Based Sound Event Detection with Semi-Supervised Learning

Chia-Chuan Liu (National Sun Yat-sen University, Taiwan); Chia-Ping Chen (National Sun Yat-Sen University, Taiwan); Chung-Li Lu, Bo-Cheng Chan, Yu-Han Cheng, Hsiang-Feng Chuang and Wei-Yu Chen (Chunghwa Telecom Laboratories, Taiwan)

P5-13

Proportionate NLMS with Variable Step-Size for Adaptive Feedback Cancellation in Hearing Aids

Linh T. T. Tran (Posts and Telecommunications Institute of Technology, Vietnam); Felix Albu (Valahia University of Targoviste, Romania); Hieu Nguyen (PTIT University, Vietnam); Nordholm Sven (Curtin University of Technology, Australia)

P5-14

Residual Echo Suppression Using Spatial Feature for Stereo Acoustic Echo Cancellation

Hsuan-Cheng Chou, Yih Liang Shen and Meng-Hsuan Wu (National Yang Ming Chiao Tung University, Taiwan); Bo-Wun Shih (Realtek Semiconductor Corporation, Taiwan); Tai-Shih Chi (National Chiao Tung University, Taiwan)

November 3 (Friday) 09:00-10:40

P5 Poster Session V

Chair: Toshio Irino (Wakayama University, Japan) / Yi-Zeng Hsieh (National Taiwan University of Science and Technology, Taiwan)

P5-15

Multitaper Adaptive Time-Frequency Windowed Fourier Transform Based on the Reliable Region of Window Widths

Jen-Chieh Cheng and Jian-Jiun Ding (National Taiwan University, Taiwan)

P5-16

Enhancing Retinal Disease Classification with Dual Scale Twin Vision Transformers Using OCT Imaging

Prakash Kumar Karn (University of Auckland, New Zealand); Waleed H. Abdulla (The University of Auckland, New Zealand)

P5-17

Classification of Infant Sleep/Wake States: Cross-Attention Among Large Scale Pretrained Transformer Networks Using Audio, ECG, and IMU Data

Kai Chieh Chang (University of Illinois at Urbana-Champaign, USA); Mark Hasegawa-Johnson (University of Illinois, USA); Nancy McElwain (University of Illinois Urbana-Champaign, USA); Bashima Islam (Worcester Polytechnic Institute, USA)

P5-18

Dynamic Characteristics of Electroencephalogram Reflecting Driving-Experience-Dependent Performance Using Microstates

Yuta Iinuma, Takuto Ozawa and Sou Nobukawa (Chiba Institute of Technology, Japan); Nobuhiko Wagatsuma (Toho University, Japan); Keiichiro Inagaki (Chubu University, Japan)

P5-19

Quefrency Domain Features with Residual Networks for Spoof Speech Detection

Madhu R Kamble (Samsung Research and Development Institute Bangalore India & Samsung India, India)

P5-20

PDF-NET: Pitch-Adaptive Dynamic Filter Network for Intra-Gender Speaker Verification

Zhenyu Piao, Hyungseob Lim, Miseul Kim and Hong-Goo Kang (Yonsei University, Korea (South))

P5-21

Subjective Evaluation of a Focused Sound Source Reproducing at the Positions of a Listener's Moving Hand

Miho Hirohashi and Yoichi Haneda (The University of Electro-Communications, Japan)

November 3 (Friday) 09:00-10:40

P5 Poster Session V

Chair: Toshio Irino (Wakayama University, Japan) / Yi-Zeng Hsieh (National Taiwan University of Science and Technology, Taiwan)

P5-22

Time Sensitive Hash and Adaptive Image Recovery Based Self-Embedding Fragile Watermarking Scheme in Encrypted Images

Xin Wang, Hongjie He and Fan Chen (Southwest Jiaotong University, China)

P5-23

Multi-Granularity Semantic and Acoustic Stress Prediction for Expressive TTS

Xiaoqin Feng (Shanghai Mobvoi Information Technology Co., Ltd, China); Yunlin Chen and Wenjiang Chi (Shanghai Mobvoi Information Technology, China); Liumeng Xue Xue (Audio Speech and Language Processing Group, China); Lei Xie (Northwestern Polytechnical University, China); Zhifei Li (Shanghai Mobvoi Information Technology, China)

P5-24

NADiffuSE: Noise-Aware Diffusion-Based Model for Speech Enhancement

Wen Wang, Dongchao Yang, Qichen Ye and Bowen Cao (PeKing University, China); Yuexian Zou (Peking University, China)

P5-25

Multi-Accent Pronunciation Assessment Based on Domain Adversarial Training

Binghuai Lin and Liyuan Wang (Tencent, China)

P5-26

GAN-Based Time-Domain Packet Loss Concealment Method with Consistent Mapping Approach

Yunhao Zhao, Changchun Bao, Xue Yang and Jing Zhou (Beijing University of Technology, China)

P5-27

MHM-Based Reversible Data Hiding with Adaptive Feature Selection

Shaowei Weng, Tanshuai Hou and Haiyang Rao (Fujian University of Technology, China)

P5-28

Feature Selection Based on Clonal Selection Algorithm for Image Steganalysis

Yu Liu and Hongxia Wang (Sichuan University, China)

P5-29

ScaleFormer: Transformer-Based Speech Enhancement in the Multi-Scale Time Domain

Tianci Wu (College of Computer Science, Inner Mongolia University, China); Shulin He (Inner Mongolia University, China)

P5-30

UniVR: A Unified Framework for Pitch-Shifted Voice Restoration in Speaker Identification

Yangfu Li and Xiaodan Lin (Huaqiao University, China)

AUTHOR INDEX

Author	Session	Title
A, Jayakrishnan	C1.1	*MSDF-Net: A Multi-Scale Deep Fusion Network with Dilated Convolutions for Cloud Removal from Sentinel-2 Imagery*
Abdulla, Waleed	A4.1	*ResNet-Based Camera Model Identification with Adaptive Preprocessing Module and Weight Fusion of Global Information*
	I5.1	*Urban Noise Monitoring Using Edge Computing with CNN-LSTM on Jetson Nano*
	P5.16	*Enhancing Retinal Disease Classification with Dual Scale Twin Vision Transformers Using OCT Imaging*
Abe, Masanobu	F3.3	*Speech Synthesis Using Ambiguous Inputs from Wearable Keyboards*
	P5.3	*Speech-Emotion Control for Text-To-Speech in Spoken Dialogue Systems Using Voice Conversion and x-Vector Embedding*
Abe, Narishige	I4.3	*Privacy-Preserving Image Transformation Method for Person Detection and Re-ID*
Abe, Takuya	A1.5	*Detection Model of Sister Chromatid Cohesion Defects Based on Vision Transformer*
Abed-Meraim, Karim	J1.2	*On the Semi-Blind Mutually Referenced Equalizers for MIMO Systems*
Abukawa, Shoya	E5.4	*Approximate Modeling of Malware Diffusion on Wireless Mobile Devices*
Adapa, Eswar	P1.1	*Fatigue Classification and Onset Estimation Using Surface EMG Signals During Strength Training*
Adiono, Trio	I1.3	*DQN Algorithm Design for Fast Efficient Shortest Path System*
Adiono, Trio	I1.2	*Human Activity Recognition Based on FMCW Radar Using CNN and Transfer Learning*
	I1.1	*A Comparative Evaluation of Video Codecs for rPPG-Based Heart Rate Estimation*
	I1.5	*Signal Quality Assessment for Wearable Multichannel Photoplethysmography Signals*
Adiono, Trio	I1.4	*Comparison of MPPT Based on Deep Reinforcement Learning by DQN, DDPG and TD3*
Adiono, Trio	I3.2	*Algorithm Development for Step-Wise Valve Deflation Method in Blood Pressure Measurement*
	I3.4	*Sparsity Exploration for Structured and Unstructured Weight Formations in CNN Architecture*

Adiono, Trio	I3.1	*A QoS Throughput Performance Measurement Comparison Between UGS and BE Services of a Real-Time FPGA Based OFDM Multi-User System Design Implementation*
	I3.3	*SUMO Based Hardware/Software Co-Simulation for Two-Intersection Adaptive and Collaborative Traffic Signal Controller*
Aditya, Ghanes	E5.2	*A Comparative Analysis of the Yolo Models for Intelligent Lobster Surveillance Camera*
Agrawal, Dharmeshkumar	P4.26	*It's What You Say and How You Say It: Exploring Audio and Textual Features for Podcast Data*
Ahmadi, Nur	I1.2	*Human Activity Recognition Based on FMCW Radar Using CNN and Transfer Learning*
	I1.1	*A Comparative Evaluation of Video Codecs for rPPG-Based Heart Rate Estimation*
	I1.5	*Signal Quality Assessment for Wearable Multichannel Photoplethysmography Signals*
Ahuja, Mitali	B2.4	*Multimodal Recognition of Speech and Electrocorticogram*
Aizawa, Jumpei	A1.3	*Manipulation of Neuronal Network Firing Patterns Using Temporal Deep Unfolding-Based MPC*
Akai, Reon	C2.4	*A Study on Eliminating Biased Node in Federated Learning*
Akhter, MD Tousin	P1.8	*FID-RPRGAN-VC: Fréchet Inception Distance Loss Based Region-Wise Position Normalized Relativistic GAN for Non-Parallel Voice Conversion*
Akhyar, Fityanul	E5.2	*A Comparative Analysis of the Yolo Models for Intelligent Lobster Surveillance Camera*
Albu, Felix	P5.13	*Proportionate NLMS with Variable Step-Size for Adaptive Feedback Cancellation in Hearing Aids*
Amadeus, Clarence	I3.2	*Algorithm Development for Step-Wise Valve Deflation Method in Blood Pressure Measurement*
An, Wenjuan	C4.5	*Feature Augmentation Reconstruction Network for Few-Shot Image Classification*
An, Yuting	P1.26	*A Visually Meaningful Image Encryption Algorithm with Attention Mechanism and Artificial Bee Colony Optimization*
Ang, Yi Yang	P3.6	*Heart Rate Acquisition and Processing Techniques for a Miniature Wearable Microphone Sensor*
Anggraini, Irin	E4.2	*OpenPose Based Yoga Poses Difficulty Estimation for Dynamic and Static Yoga Exercises*
Anh, Anh	A3.4	*An Automatic Pipeline for Building Emotional Speech Dataset*

Anistyasari, Yeni	B5.1	*ASF-LLRDA: Locality-Regularized Linear Regression Discriminant Analysis with Approximately Symmetrical Face Preprocessing for Face Recognition*
Aoki, Remi	P3.1	*Remarks on an Optimal Predictive Control Using a Quaternion Neural Network and a Metaheuristics Optimisation Method*
Aoki, Takafumi	I4.4	*Eye Biometrics Combined with Periocular and Iris Recognition Using CNN*
Arablouei, Reza	G3.2	*Continual Local Updates for Federated Learning with Enhanced Robustness to Link Noise*
Arakawa, Takahiko	I4.5	*Development of a Robust Ear Recognition Algorithm Using Planar Approximation*
Araki, Shoko	B3.1	*Modified Parametric Multichannel Wiener Filter for Low-Latency Enhancement of Speech Mixtures with Unknown Number of Speakers*
	A5.5	*Spatially-Regularized Switching Independent Vector Analysis*
Armunanta, Dwi	P3.24	*Efficient Dictionary and Grid-Based Framework for Answering Durable k-Nearest Neighbor Queries on Time Series Data*
Arvaneh, Mahnaz	P1.6	*Predicting Outcomes of Cognitive Behavioral Therapy for Depression Using Data Driven Approaches*
Asami, Taichi	H5.1	*Coarse-Age Loss: A New Training Method Using Coarse-Age Labeled Data for Speaker Age Estimation*
Baguio, Tyler	G3.4	*Distributed On-Line Anomaly Detection Using Kernel Methods*
Bah, Mohamed	D2.1	*Interpretable Image Recognition in Hyperbolic Space*
Bai, Mingsian	H3.2	*Multichannel Learning-Based Spatially Extended Active Noise Control via Model Matching and Sensor Transfer Function Interpolation*
Bai, Zhongxin	B3.5	*A Weighted Binary Cross-Entropy for Sound Event Representation Learning and Few-Shot Classification*
Bando, Yoshiaki	C5.1	*DOA-Aware Audio-Visual Self-Supervised Learning for Sound Event Localization and Detection*
Banerjee, Padmanabha	P1.8	*FID-RPRGAN-VC: Fréchet Inception Distance Loss Based Region-Wise Position Normalized Relativistic GAN for Non-Parallel Voice Conversion*
Bao, Changchun	P5.26	*GAN-Based Time-Domain Packet Loss Concealment Method with Consistent Mapping Approach*
Barhumi, Imad	P3.3	*Compressive Sensing Based Algorithms for Limited-View PAT Image Reconstruction*
Barua, Hrishav	J2.2	*ArtHDR-Net: Perceptually Realistic and Accurate HDR Content Creation*
Baskaran, Vishnu Monn	F4.5	*HDR Image Watermarking Based on Saliency Detection and Quantization Index Modulation*

Benesty, Jacob	B3.5	*A Weighted Binary Cross-Entropy for Sound Event Representation Learning and Few-Shot Classification*
	P4.29	*A Controlled Noise Reduction Wiener Filter Based on the Quadratic Eigenvalue Problem*
Benner, Seico	H5.4	*Automatic Call Classification of Autism Model Marmosets by Deep Learning and Analysis of Their Vocal Development*
Bhardwaj, Mohit	P4.26	*It's What You Say and How You Say It: Exploring Audio and Textual Features for Podcast Data*
Bhat, Savita	P4.26	*It's What You Say and How You Say It: Exploring Audio and Textual Features for Podcast Data*
Boodhoo, Kirish	P3.6	*Heart Rate Acquisition and Processing Techniques for a Miniature Wearable Microphone Sensor*
Bu, Bing	P2.28	*Single Source Zone Detection in the Spherical Harmonic Domain for Multisource Localization*
Buaruk, Suphachok	D4.6	*Enhancing Snoring Detection with Statistical Analysis of Audio Features*
Buttelli, Olivier	J1.1	*After-Fatigue Condition: A Novel Analysis Based on Surface EMG Signals*
Cai, Tao	D4.1	*A Cloud-Based Data Platform for Efficient EEG Data Management, Collaboration, and Analysis*
Cai, Yunrui	P2.29	*Robust Representation Learning for Speech Emotion Recognition with Moment Exchange*
Cao, Bowen	P5.24	*NADiffuSE: Noise-Aware Diffusion-Based Model for Speech Enhancement*
Chai, Abel Yu Hao	D2.4	*Unveiling Robust Feature Spaces: Image vs. Embedding-Oriented Approaches for Plant Disease Identification*
Chai, AiFang	J2.6	*ELEGANT: End-To-End Language Grounded Speech Denoiser for Efficient Generation of Talking Face*
Chai, Kok Chin	D2.6	*How Transferable are Herbarium-Field Features in Few-Shot Plant Identification with Triplet Loss?*
	D2.3	*MoMo Strategy: Learn More from More Mistakes*
Chaiwongyen, Anuwat	G5.1	*Deepfake-Speech Detection with Pathological Features and Multilayer Perceptron Neural Network*
Chalothorn, Tawunrat	BS1.4	*Residual, Mixer, and Attention: The Three-Way Combination for Streaming Wake Word Detection Framework*
Chan, Bo-Cheng	P3.16	*A Lightweight Speaker Verification Model for Edge Device*
	P5.12	*Regression-Based Sound Event Detection with Semi-Supervised Learning*

Chan, Kai-Hsuan	G5.4	*Reduction of Annotation Effort in Medical Image Analysis Based on Self-Supervised Learning*
Chan, Mei-Ling	P2.13	*Dental Positioning Medical Assistance System for BiteWing Radiograph Based on YOLOV4 and Image Enhancement*
	B4.4	*Point Cloud Inpainting Based on Delaunay Triangulation*
	P4.11	*Application of Deep Learning Techniques for Thermal Imagery Analysis in Abnormal Identification of Floor Tiles in Heritage Environments*
Chang, Arthur	C3.2	*Automated Carina Detection in Chest X-Ray Images Using Non-Overlapping and Cross-Squeeze Convolutional Neural Networks*
Chang, Cheng-Yuan	H3.3	*A Study of the Microphone Protection of Active Noise Control for Axial Fan*
Chang, Ching Hsiang	P1.15	*Old Damaged Photo Recovery with Style Transfer-Based Data Augmentation*
Chang, Ching-Chun	C2.2	*Image-Text Out-Of-Context Detection Using Synthetic Multimodal Misinformation*
Chang, Chuan-Yu	C3.5	*Integration of Contextual Information with YOLOv5 for Detecting Tracheobronchial Foreign Objects*
Chang, Dongliang	P1.29	*Multi-Frequency Feature Enhancement for Multi-Granularity Visual Classification*
Chang, Jie-Fan	H2.4	*Light-Weight Zero-Reference-Based Image Enhancement for Low-Light Images*
Chang, Jih-Sheng	I5.3	*A Framework for Reusing Earth Science Data on Data and Model Marketplaces*
Chang, Kai Chieh	P5.17	*Classification of Infant Sleep/Wake States: Cross-Attention Among Large Scale Pretrained Transformer Networks Using Audio, ECG, and IMU Data*
Chang, Ku-Yaw	H2.4	*Light-Weight Zero-Reference-Based Image Enhancement for Low-Light Images*
Chang, Li-Jen	BS1.6	*Mask2Hand: Learning to Predict the 3D Hand Pose and Shape from Shadow*
Chang, Min-Kuan	D5.5	*Autoencoder-Enhanced Federated Learning with Reduced Overhead and Lower Latency*
Chang, Shih-Chieh	G1.2	*Gait Analysis in Powered Exoskeleton-Assisted Walking in Patients with Stroke: A Case Series Cohort*
Chang, Ting-Yu	B5.4	*Multitask Record for Badminton Match*
Chang, Wen-Yi	I5.3	*A Framework for Reusing Earth Science Data on Data and Model Marketplaces*

Chang, Yang Loong	D2.6	*How Transferable are Herbarium-Field Features in Few-Shot Plant Identification with Triplet Loss?*
	D2.3	*MoMo Strategy: Learn More from More Mistakes*

	P2.10	*Improving Regularization of Deep Learning Models in Fundus Analysis*
Chang, Yen-Ching	P2.14	*Asynchronous Federated Learning Method in the 6G Massive Multimedia Transmission System*
Chang, Yi-Cheng	F5.2	*Study on the Reduction of Background Fringes for Detect Detection on Specular Surface*
Chang, Yu-Jen	H1.1	*Machine Learning Based Action Recognition with Modular CNN*
Chanpornpakdi, Ingon	BS1.3	*Event-Related Potential in Rapid Serial Visual Presentation-Based Partial Face Cognition Depends on Visible Face Components*
Chao-Tsung, Huang	P3.15	*A Biased Mixed-Precision Convolution Engine for Hardware-Efficient Computational Imaging CNN*
Charlton, Peter	I1.1	*A Comparative Evaluation of Video Codecs for rPPG-Based Heart Rate Estimation*
	I1.5	*Signal Quality Assessment for Wearable Multichannel Photoplethysmography Signals*
Chen, Berlin	P5.11	*AVATAR: Robust Voice Search Engine Leveraging Autoregressive Document Retrieval and Contrastive Learning*
Chen, Boru	A4.1	*ResNet-Based Camera Model Identification with Adaptive Preprocessing Module and Weight Fusion of Global Information*
Chen, Chen	E3.3	*Study of Generative Adversarial Networks for Noisy Speech Simulation from Clean Speech*
Chen, Chi-Yuan	C3.2	*Automated Carina Detection in Chest X-Ray Images Using Non-Overlapping and Cross-Squeeze Convolutional Neural Networks*
Chen, Chia-Ping	P3.16	*A Lightweight Speaker Verification Model for Edge Device*
	P5.12	*Regression-Based Sound Event Detection with Semi-Supervised Learning*
Chen, Chien-Chih	I5.2	*Random Forest of Classification and Regression Tree (CART) in the Estimation of SWC Based on Meteorological Inputs and Hydrodynamics Behind*
Chen, Chien-Ching	B1.4	*Collaborative Pseudo Labeling for Prompt-Based Learning*
Chen, Ching-Chieh	P4.9	*Classification of Vocal Cord Disorders: Comparison Across Voice Datasets, Speech Tasks, and Machine Learning Methods*
Chen, Chiung-An	P2.8	*VLSI Design of Lossless Image Compression Using Improved LZW*

	P2.13	*Dental Positioning Medical Assistance System for BiteWing Radiograph Based on YOLOV4 and Image Enhancement*
	B4.3	*Identification of Victims Wearing Vibrant Clothing Using MATLAB*
	P4.11	*Application of Deep Learning Techniques for Thermal Imagery Analysis in Abnormal Identification of Floor Tiles in Heritage Environments*
	B4.2	*The VLSI Design DSP and DDR4 for Multi-Sensor in Biomedical System*
Chen, Cynthia	G3.3	*Multi-Task Gaussian Process Learning to Fill in Gaps in LBS Mobile Data*
Chen, Duan-Yu	P1.12	*Lightweight Models Distillation with Learnable Teaching Material: An Application for Smart Table Tennis System*
Chen, Fan	P5.22	*Time Sensitive Hash and Adaptive Image Recovery Based Self-Embedding Fragile Watermarking Scheme in Encrypted Images*
Chen, Fang-Ching	H1.5	*Utilizing Unlabeled Data and Synthetic Data for Bird Sound Detection: Consistency Training, Mean Teacher, and Domain Adaptation Techniques*
Chen, Fei	B2.2	*Cross-Subject Classification of Spoken Mandarin Vowels and Tones with EEG Signals: A Study of End-To-End CNN with Fine-Tuning*
	P3.23	*Assessing the Effects of Filtering Processing on Pulse Wave Transit Time Measured by Photoplethysmography from Earlobe*
Chen, Gong	B3.5	*A Weighted Binary Cross-Entropy for Sound Event Representation Learning and Few-Shot Classification*
Chen, Hang	D1.2	*Correlated Multi-Level Speech Enhancement for Robust Real-World ASR Applications Using Mask-Waveform-Feature Optimization*
	P2.26	*Improved Data2vec with Soft Supervised Hidden Unit for Mandarin Speech Recognition*
	P2.25	*Progressive Multi-Scale Self-Supervised Learning for Speech Recognition*
	C2.6	*Enhancing Privacy Preservation with Quantum Computing for Word-Level Audio-Visual Speech Recognition*
Chen, Heliu	P1.23	*CoA-DLinkNet: Connectivity-Enhanced Dual-Branch Road Extraction Network Based on D-LinkNet*
Chen, Hui-Lin	P3.19	*DOC: A Novel DOuble-Contour-Based Macro Placement Framework for Mixed-Size Designs*
Chen, Hwann-Tzong	BS1.6	*Mask2Hand: Learning to Predict the 3D Hand Pose and Shape from Shadow*
Chen, Jeffrey	B5.4	*Multitask Record for Badminton Match*
Chen, Jia-Hong	P1.14	*Analysis of the Interaction Effect on Pruning and Transfer Learning in Model Training*

Chen, Jingdong	P1.20	*A Subband Approach to Personal Sound Zone with Joint Optimization of Sound Pressure and Particle Velocity*
Chen, Jingdong	B3.5	*A Weighted Binary Cross-Entropy for Sound Event Representation Learning and Few-Shot Classification*
	E3.2	*On Joint Dereverberation and Source Separation with Geometrical Constraints and Iterative Source Steering*
Chen, Jingdong	P4.29	*A Controlled Noise Reduction Wiener Filter Based on the Quadratic Eigenvalue Problem*
Chen, Jun-Cheng	BS1.1	*Enhancing Real-Time Semantic Segmentation with Textual Knowledge of Pre-Trained Vision-Language Model: A Lightweight Approach*
Chen, Junjie	P4.25	*Hybrid Multi-Task Learning for End-To-End Multimodal Emotion Recognition*
Chen, Kuan-Dar	P4.9	*Classification of Vocal Cord Disorders: Comparison Across Voice Datasets, Speech Tasks, and Machine Learning Methods*
Chen, Lei	P1.30	*Improving Aspect Sentiment Classification via Retrieving from Training Data*
Chen, Ming-Yen	B1.5	*Learning Meta Soft Prompt for Few-Shot Language Models*
Chen, Pei-Yuan	I5.2	*Random Forest of Classification and Regression Tree (CART) in the Estimation of SWC Based on Meteorological Inputs and Hydrodynamics Behind*
Chen, Po-Kai	F5.5	*Question Answering System Based on Pre-Training Model and Retrieval Reranking for Industry 4.0*
Chen, Po-See	G5.2	*Temporal and Type Correlation in Digital Phenotyping for Bipolar Disorder State Prediction Using Multitask Self-Supervised Learning*
Chen, Qian	P4.21	*A Comparative Study on Multichannel Speaker-Attributed Automatic Speech Recognition in Multi-Party Meetings*
Chen, Shih-Lun	P2.13	*Dental Positioning Medical Assistance System for BiteWing Radiograph Based on YOLOV4 and Image Enhancement*
	P2.9	*The Color Demosaicing and Image Scaling Based on Improve Hamilton-Adams*
	B4.4	*Point Cloud Inpainting Based on Delaunay Triangulation*
	B4.1	*3D Point Cloud Denoising Based on Color Attribute*
	P4.11	*Application of Deep Learning Techniques for Thermal Imagery Analysis in Abnormal Identification of Floor Tiles in Heritage Environments*
	B4.2	*The VLSI Design DSP and DDR4 for Multi-Sensor in Biomedical System*
Chen, Sze-Ann	G4.5	*Virtual Garment Fitting Through Parsing and Context-Aware Generative Adversarial Networks with Discriminator Group*

Chen, Ta-Fu	F5.5	*Question Answering System Based on Pre-Training Model and Retrieval Reranking for Industry 4.0*
Chen, Ting-Wei	P3.16	*A Lightweight Speaker Verification Model for Edge Device*
Chen, Tsung-Ping	F1.3	*Learning Multifaceted Self-Similarity for Musical Structure Analysis*
Chen, Tsung-Yi	P2.13	*Dental Positioning Medical Assistance System for BiteWing Radiograph Based on YOLOV4 and Image Enhancement*
	P4.11	*Application of Deep Learning Techniques for Thermal Imagery Analysis in Abnormal Identification of Floor Tiles in Heritage Environments*
Chen, Tzu-Chieh	C3.1	*A Reconfigurable Hardware Architecture for Graph Convolution Network in Action Recognition*
Chen, Wei-Yu	P3.16	*A Lightweight Speaker Verification Model for Edge Device*
	P5.12	*Regression-Based Sound Event Detection with Semi-Supervised Learning*
Chen, Wei-Yu	I5.3	*A Framework for Reusing Earth Science Data on Data and Model Marketplaces*
Chen, Wen-Ru	E5.5	*Impacts of 5G-TDD Time Slot Configurations on the Downlink and Uplink Data Rates*
Chen, Xianhong	P2.23	*Multi-Task Piano Transcription with Local Relative Time Attention*
Chen, Xin-Yu	P4.11	*Application of Deep Learning Techniques for Thermal Imagery Analysis in Abnormal Identification of Floor Tiles in Heritage Environments*
Chen, Xingyan	C4.3	*Privacy-Oriented Coded Caching in Mobile Information-Centric Network*
Chen, Xingyu	P4.28	*Sound Field Estimation Around a Rigid Sphere with Physics-Informed Neural Network*
Chen, Yan	P2.17	*STrack: Velocity Estimation Using Single Antenna WiFi Devices*
Chen, Yan-Hao	P1.16	*A Deep Learning Based Sustainable Energy Scheduling System*
Chen, Yan-Ru	B4.6	*Safety Enhancement for Mobility Scooter with Rule-Based Danger Prevention*
Chen, Yanli	P3.26	*Fine-Grained Face Anti-Spoofing Based on Recursive Self-Attention and Multi-Scale Fusion*
Chen, Yen-Hsin	A4.6	*Exploring a CLIP-Enhanced Automated Approach for Video Description Generation*
Chen, Yi-Hsin	G4.3	*Transformer-Based Image Compression with Variable Image Quality Objectives*
Chen, Yong-Tai	P3.15	*A Biased Mixed-Precision Convolution Engine for Hardware-Efficient Computational Imaging CNN*
Chen, You-Siang	H3.2	*Multichannel Learning-Based Spatially Extended Active Noise Control via Model Matching and Sensor Transfer Function Interpolation*

Chen, Young-Long	E4.4	*Learned String Quartet Music with Variational Auto Encoder*
Chen, Yu-Guang	P3.19	*DOC: A Novel DOuble-Contour-Based Macro Placement Framework for Mixed-Size Designs*
Chen, Yu-Hsuan	P1.12	*Lightweight Models Distillation with Learnable Teaching Material: An Application for Smart Table Tennis System*
Chen, Yu-Jen	P1.13	*Selecting Suitable Data Input for Deep-Learning Sign-Language Recognition with a Small Dataset*
Chen, Yueru	J2.3	*LSR++: An Efficient and Tiny Model for Image Super-Resolution*
Chen, Yunlin	P5.23	*Multi-Granularity Semantic and Acoustic Stress Prediction for Expressive TTS*
Cheng, Cheng-Hsu	G1.2	*Gait Analysis in Powered Exoskeleton-Assisted Walking in Patients with Stroke: A Case Series Cohort*
Cheng, Cuiping	P1.21	*An Multi-Evidence Fusion Based on C-Distance with Uncertain Reasoning for Classification*
	P2.27	*Investigation of Ensemble of Self-Supervised Models for Speech Emotion Recognition*
Cheng, Fang-Yi	I5.4	*Impact of the Weighted Loss Function on the Innovative CMAQ-CNN PM2.5 Forecasting Model*
Cheng, Haowei	P4.2	*Analysis of Spectro-Temporal Modulation Representation for Deep-Fake Speech Detection*

***Abstract*— Advanced emotion monitoring and intervention systems are critical for human-machine cooperation to finish specific tasks in which recognizing mixed emotions is essential. This study is the first to propose intelligent recognition methods of mixed emotions based on EEG signals, thus endowing machines with higher emotional intelligence. We extracted differential entropy (DE), differential asymmetry (DASM), and rational asymmetry (RASM) as features. To better serve the system application and promotion, this study selected three lightweight classifiers, including Random Forest (RF), Probabilistic Neural Networks (PNN), and Generalized Regression Neural Networks (GRNN), all of which achieved good classification performance. The highest classification accuracy is 96.7%. The results of this study can be applied in the fields of mental state assessment, psychological assistance, and clinical psychotherapy.**

I. INTRODUCTION

Emotions are not discretely experienced but often co-occur as mixed emotions simultaneously [1]. Just like mixing painting colors on a palette, mixed emotions are the concrete manifestation of the richness and diversity of human emotions and can more truly reflect the actual emotional state and colorful life experience of individuals [2,3]. In Chinese proverbs, this state is described as “Five flavors in the heart”. As a universal affective experience, mixed emotions are characterized by the co-activation of different dimensions of emotions [1,4,5]. Typically, homogeneously mixed emotions consist of basic emotions with the same valence, such as happiness-pleasure or sadness-fear. In contrast, heterogeneously mixed emotions are blended with basic emotions with different valences, such as happiness-sadness or excitement-fear [6]. From the perspective of discrete emotion models, too many basic emotion combinations lead to low operability and feasibility for further research, such as Plutchik's Wheel of Emotions [7]. Therefore, our research divides mixed emotions into four categories (positive mixed emotions vs. negative mixed emotions vs. neutral mixed emotions vs. heterogeneously mixed emotions) from the perspective of the dimensional emotion model [8].

The recognition of mixed emotions is of great significance. In goal-oriented tasks such as driving a car, working at heights, and emergency rescue, individuals are always in a mixed emotional state. At the same time, they must select and retain task-relevant information and screen out interference from task-irrelevant distractors [9]. It requires balancing adaptation to complex affective states and cognitive control of task-relevant information. In particular, different mixed emotions may have dissociable effects on cognitive control [2,5]. Therefore, the primary goal of advanced emotion monitoring and intervention systems is to develop intelligent methods for mixed emotion recognition, enabling machines to judge and understand complex individual emotional states [10].

Previous studies have confirmed that mixed emotions can be recognized from different perspectives [6,11]. For example, from a behavioral evidence perspective, Larsen and McGraw [6] developed a button press measure for mixed emotions. The results showed that participants who watched the bittersweet movie clips reported mixed emotional experiences. From the perspective of machine vision evidence, one work defines fifteen mixed emotion categories based on the combination of separable action units of facial expressions [11,12]. As the regulating organ of the human body functions and the source of EEG signals, the brain’s neural activity determines the individual’s keystroke behavior and facial expression changes. Therefore, it is possible to describe the patterns and boundaries of mixed emotions based on the electrophysiological evidence. In addition, EEG signals are not easily disguised (so-called social masking) and thus more objective and reliable than behavioral and facial expression data in emotion recognition.

One of the challenging issues for EEG-based emotion recognition using machine learning is a lack of large and available dataset. In particular, there is no open-source EEG dataset of mixed emotion. Therefore, we have to autonomously collect EEG data for algorithm training and testing under the condition of inducing mixed emotional states. There are two main approaches to activate mixed emotions: stimulus-induced and task-induced. The former is a way to present participants

979-8-3503-0067-3/23/$31.00 ©2023 IEEE

with stimuli containing mixed emotional cues, such as movie clips [6,13], paired pictures [14,15] and music [16]. In stimulus induction, participants undergo a mixed-emotional self-assessment procedure either during or after the presentation. There is a need for a scientific manipulation examination of the material's effectiveness in eliciting mixed emotions. Task induction is accomplished by making participants engage in and perform specific tasks, such as performing computer game tasks, freehand drawing tasks, recall tasks, etc., during which participants self-assess their emotions [4,17,18]. The difference between the two methods is whether the participant passively receives the mixed emotional stimulus or actively participates in the eliciting activity. While the latter is considered ecologically more efficient, the former is more mature and standardized. The paired-picture paradigm was used in this study [14,15], with pictures from the International Affective Picture System (IAPS).

The research on mixed emotion classification and recognition based on EEG signals is limited to our knowledge. Therefore, we review the relevant research on basic emotion recognition and signal monitoring system design, hoping to draw valuable lessons. Directly using raw or preprocessed EEG data for classification is computationally intensive, with poor classification effect and low interpretability. Therefore, most studies are based on the inevitable feature extraction of preprocessed EEG signals, followed by classification using classifiers [19,20]. Drawing on previous basic emotion classification and recognition methods, we extract differential entropy (DE), differential asymmetry (DASM), and rational asymmetry (RASM) as features, which are usually used to classify emotions of different valences with outstanding performance [21-23].

To better serve the design of emotion monitoring and intervention systems, this study tried three lightweight classifiers, namely Random Forest (RF), Probabilistic Neural Networks (PNN), and Generalized Regression Neural Networks (GRNN), hoping to take into account both classification performance and computational efficiency, to provide adequate support for future practical applications. RF is a decision tree-based ensemble learning algorithm that can directly process data containing high-dimensional features. RF has high prediction accuracy, low computational overhead, good tolerance to outliers and noise, and is not prone to overfitting [24,25]. PNN combines Bayesian decision theory and density function estimation in radial basis neural networks [26]. During the modeling process, the decision boundary realized by PNN asymptotically approaches the Bayes optimal decision surface. Its structure is simple and easy to implement. It also has the characteristics of fast operation [27]. As a generalization of PNN networks, GRNN networks do not require an iterative process for training, and a high degree of parallelism is presented in their structure [28], which has strong nonlinear mapping ability, local approximation ability, and fast learning ability, as well as the high degree of fault tolerance and robustness [29]. The classification performance of the three methods was compared.

II. Materials And Methods

A. Participants

A total of 25 participants were recruited. Data from two participants were deleted due to excessive recording artifacts. There were 23 valid participants (including 12 females) aged 18-27 (mean = 22.23, SD = 2.20) for final data analysis. They were right-handed, native Chinese speakers with normal or corrected-to-normal vision but no color blindness or weakness. They had no history of neurological or psychiatric disorders. The ethics committee approved the study. Before the experiment, all subjects signed a written informed consent form informing the experiment time, purpose, content, equipment, and procedures. Before the formal experiment began, participants were told they would receive ¥ 45 (~ $ 7.0) as compensation for their participation.

B. Materials

This study employed the paired-picture paradigm [15] and selected stimulus material from the IAPS. The IAPS is widely used in emotional psychology research and contains parameters of various dimensions (e.g., valence, arousal, dominance) obtained from the subjective evaluation results of Western participants. Mixed emotions are elicited and differentiated based on individual evaluations of different pictures, heavily influenced by cultural and social norms [30]. It is inappropriate to directly apply the IAPS rating results of Western participants to Chinese participants. We chose to use the evaluation summary table (704 pictures version) in Mainland China produced by the team of Professor Zhou Renlai from the Department of Psychology of Nanjing University to select the images needed for the experimental stimulus. 120 positive, negative, and neutral images are used, respectively. We performed ANOVA and compared potency for positive, negative, and neutral images. The difference in image valence between the pictures was very significant ($F_{2,357} = 4482.56$, $p < 0.001$), as shown in Table 1. The average valance score was 7.08 (SD = 0.400) for positive images, 5.00 (SD = 0.212) for neutral images, and 2.68 (SD = 0.428) for negative images (Table I).

TABLE I
THE EVALUATION RESULTS OF THE STIMULUS MATERIALS

Index	Measurements	Positive Pictures	Negative Pictures	Neutral pictures
Valence	Mean	7.080	2.680	5.000
	SD	0.400	0.428	0.212
Arousal	Mean	5.750	5.370	4.890
	SD	0.572	0.635	0.736

Index	Measurements	Positive Pictures	Negative Pictures	Neutral pictures
Dominance	Mean	3.640	6.180	4.710
	SD	0.458	0.532	0.501

C. Experimental Procedure

After reading the printed instructions, participants were directed to a soundproofed and electrically shielded room. The stimuli were presented in the center of the computer screen at a viewing angle of 7.50°×5.40°, with a distance of 100 cm. A keyboard was provided for the subjects to complete the Stroop task. The Stroop task has two functions in this study: on the one hand, it is to confirm that participants have completed the entire experimental task seriously; on the other hand, it is to perform emotional erasure to reduce the interference between trials. The experiment consisted of eight blocks, each containing 40 trials. The formal experiment started after ten practice trials to familiarize the participants with the experimental task.

At the beginning of each trial, a fixation appeared in the center of the screen for 500 ms, prompting participants to pay attention. As a priming phase, two emotional stimuli images were presented on the screen for 1500 ms. According to the different emotional valences evoked by the stimulus pictures, it is divided into four different categories: positive mixed emotions (a combination of positive-positive images), negative mixed emotions (a combination of negative-negative images), heterogeneously mixed emotions (a combination of positive and negative images) and neutral mixed emotions (a combination of neutral-neutral images). The word "red" or "green" appeared on the screen for 1000 ms as the target phase after a 500 ms inter-stimulus interval. In some trials, goal-unrelated information was consistent with goal-related information (e.g., the word "green" was printed in green ink); in other trials, the two were inconsistent (e.g., the word "green" was printed in red ink). Then, the prompt sentence "Please click on the text color" appeared. Participants were asked to judge the color of the text by pressing "1" or "3" as quickly as possible. The colors corresponding to the buttons were balanced among the participants. The inter-trial interval is 500 ms. Participants had 2-3 min between blocks to rest and relax (Fig. 1).

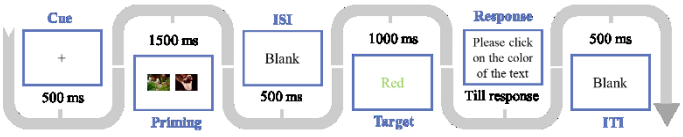

Fig. 1 Trial flow chart. It showed the procedure of one trial, and there were 320 trials in total.

Note. ISI = inter-stimulus interval; ITI = inter-trial interval.

D. Behavioral Data Acquisition and Analysis

The main purpose of our detection of behavioral data is to confirm that the subjects participated in this experiment seriously. Behavioral data were collected using E-prime 2.0 software (Psychology Software Tools Inc., Pittsburgh, PA, USA) and exported. After obtaining the original behavioral data, we used SPSS 25.0 statistical software (SPSS, Inc., Chicago, IL, USA) to perform the repeated-measures analysis of variance (ANOVAs) [4 (priming conditions) × 2 (Stroop conditions)].

E. EEG Data Acquisition and Analysis

Raw electroencephalographic (EEG) data were acquired using a Neuroscan Synamp2 Amplifier (Neurosoft Labs, Inc., Sterling, Virginia, USA) with Ag/AgCl electrodes placed at 64 scalp sites according to the extended international 10-20 system, with an online bandpass of 0.5-70 Hz and at a sampling rate of 500 Hz. The left mastoid served as the online reference, and the EEG was re-referenced offline to the mathematically averaged mastoids. Two pairs of electrodes recorded vertical and horizontal electrooculograms (EOGs). One pair was placed above and below the left eye parallel with the pupil, and the other was placed 10 mm from the lateral canthi. Impedances were kept below 5 kΩ throughout the experiment. EEG data were further processed offline using the Matlab EEGLab toolbox (Mathworks, Inc., Natick, MA, USA). Bandpass filters the EEG data at 0.5-50 Hz using a zero-phase-shift FIR filter. A notch filter removes electrical interference from 50 Hz line noise [31]. EEG data were down-sampled at a sampling frequency of 256 Hz to speed up calculations. Brain-independent artifacts such as significant muscle activity and eye movements were removed using independent component analysis [32]. The signal was then segmented for the emotion recognition phase to analyze the period from 500 ms before the presentation of mixed pictures to 1500 ms after the presentation. We divide the [0 ms, 1500 ms] data into 15 sub-epochs of 100 ms. Hanning filters are used to extract the delta (1-3 Hz), theta (4-7 Hz), alpha (8-13 Hz), beta (14-30 Hz), and gamma (31-49 Hz) bands. Baseline correction was applied to each frequency band in a time window from -500 to 0 ms relative to stimulus onset. Three features (DE, DASM, and RASM) were extracted. DE can be used to describe the chaotic nature of EEG signals as entropy the degree of variability and complexity of the system. DE is equivalent to the logarithmic energy spectrum, where the time series X obeys the Gaussian distribution $N(\mu,\delta 2)$.

$$h(X) = -\int_{-\infty}^{\infty} \frac{1}{\sqrt{2\pi\sigma^2}} e^{-\frac{(x-\mu)^2}{2\sigma^2}} log\left(\frac{1}{\sqrt{2\pi\sigma^2}} e^{-\frac{(x-\mu)^2}{2\sigma^2}}\right) dx = \frac{1}{2} log(2\pi e\sigma^2) \quad (1)$$

DASM and RASM are the differences and ratios between DE of 27 pairs of hemispheric asymmetry electrodes (left-right: *FP1-FP2, F7-F8, F3-F4, FT7-FT8, FC3-FC4, T7-T8, P7-P8, C3-C4, TP7-TP8, CP3-CP4, P3-P4, O1-O2, AF3-AF4, F5-F6, F7-F8, FC5-FC6, FC1-FC2, C5-C6, C1-C2, CP5-CP6, CP1-CP2, P5-P6, P1-P2, PO7-PO8, PO5-PO6, PO3-PO4, and CB1-CB2*), which can be calculated as

$$DASM = h(X_i^{left}) - h(X_i^{right}) \quad (2)$$

$$RASM = h(X_i^{left})/h(X_i^{right}) \quad (3)$$

where $h(X)$ is defined in Equation 1, and i is the pair number.

The processed features were further applied to mixed emotion classification (positive mixed emotions vs. negative mixed emotions vs. neutral mixed emotions vs. heterogeneously mixed emotions) using RF, PNN, and GRNN. RF is an ensemble learning method. In this study, the outputs of multiple decision trees were combined to obtain a single result, which was trained using bagging. In our model, the number of trees in the forest is 100, and the maximum depth of the trees is 500. PNN is a neural network technique based on Bayesian decision rules. In this study, PNN includes four network layers: input, pattern, summation, and output. When an input is presented, the pattern layer computes distances from the input vector to the training input vectors. It produces a vector whose elements indicate how close the input is to a training input. The summation layer sums these contributions for each class of inputs to produce as its net output a vector of probabilities. Finally, a compete transfer function on the output of the summation layer picks the maximum of these probabilities, and produces a 1 for that class and a 0 for the other classes.

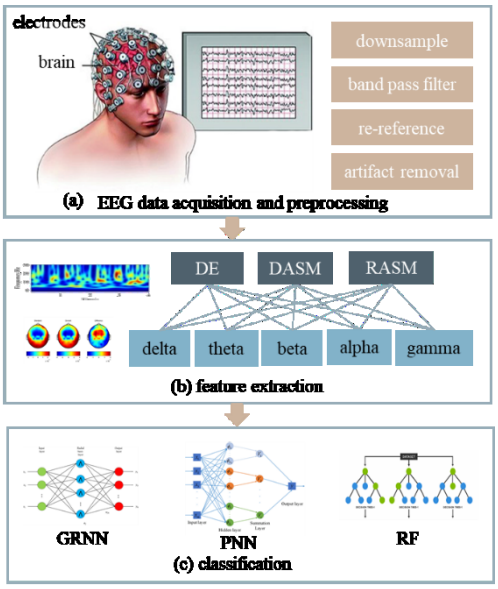

Fig. 2 Flow chart of EEG data processing for mixed emotion classification

GRNN is a generalization of PNN networks. Different from PNN, GRNN adopts linear output instead of competitive output. The input layer receives the input signal and transmits it to the hidden layer; the hidden layer is composed of basis functions, which produce different responses to the input signal; the output layer is composed of linear functions. We applied the 10-fold cross-validation strategy to estimate the generalization ability of our classifiers. We selected several performance indicators for the classification models, including accuracy, precision, recall, and F1 (macro-averaged F1-score).

III. Results

A. Behavioral Results

We conducted a two-way 4 (mixed emotion priming conditions) × 2 (Stroop conditions) repeated measures ANOVA for reaction accuracy (see Table II). There was a significant main effect of the Stroop condition ($F_{1,22} = 8.751$, $p = 0.007$), and the accuracy rate in the congruent condition (M = 0.995, SD = 0.012) was significantly greater than that in the incongruent condition (M = 0.985, SD = 0.024), while the main effect of the priming condition ($F_{3,20} = 1.366$, $p = 0.282$) and the interaction effect of these two factors ($F_{3,20} = 0.349$, $p = 0.790$) were not significant.

TABLE II
DESCRIPTIVE STATISTICS OF REACTION ACCURACY UNDER DIFFERENT CONDITIONS

Conditions	Min	Max	Mean	SD
negative - incongruent	0.93	1.00	0.985	0.022
negative - congruent	0.95	1.00	0.993	0.014
neutral - incongruent	0.90	1.00	0.985	0.033
neutral - congruent	0.98	1.00	0.999	0.005
heterogeneous - incongruent	0.95	1.00	0.989	0.017
heterogeneous - congruent	0.98	1.00	0.996	0.010
positive - incongruent	0.93	1.00	0.982	0.026
positive - congruent	0.95	1.00	0.991	0.018

B. EEG Results

The performance of classifiers based on features from different frequency bands is shown in Table III. Mixed emotion classification methods proposed have achieved good classification results, and the classification accuracy can generally reach 96%. Significantly, based on the gamma frequency band features, the classification accuracy of PNN reached the highest, 96.7%. In addition, the features from the various frequency bands do not show significant differences in mixed emotion classification. Generally speaking, the accuracy has reached the expected effect and has good applicability.

TABLE III
PERFORMANCE OF CLASSIFIERS IN DIFFERENT FREQUENCY BANDS

Classifier	band	Accuracy	Precision	Recall	F1
RF	delta	0.961	0.923	0.921	0.922
	theta	0.961	0.925	0.875	0.895
	alpha	0.963	0.925	0.924	0.924
	beta	0.965	0.934	0.876	0.899
	gamma	0.963	0.929	0.876	0.896
GRNN	delta	0.962	0.923	0.912	0.917
	theta	0.963	0.927	0.876	0.897
	alpha	0.964	0.928	0.923	0.925

Classifier	band	Accuracy	Precision	Recall	F1
PNN	beta	0.960	0.916	0.882	0.897
	gamma	0.963	0.926	0.925	0.925
	delta	0.951	0.921	0.860	0.861
	theta	0.958	0.921	0.918	0.909
	alpha	0.961	0.923	0.939	0.925
	beta	0.965	0.924	0.954	0.935
	gamma	0.967	0.922	0.962	0.939

IV. DISCUSSION

Mixed emotion recognition embodies advanced emotional intelligence in emotion monitoring and intervention systems. This study is the first to propose an intelligent recognition method of mixed emotions based on EEG signals so that the machine can perceive and identify one's mixed emotion state.

For the behavioral data results, the reaction accuracy under each condition was greater than 93%, indicating that all participants accurately understood the experimental task and completed it with high quality, with relatively intense concentration throughout the experiment. The reaction accuracy results show a significant main effect of the Stroop condition. The accuracy in the congruent condition was significantly greater than that in the incongruent condition. This result is consistent with previous studies [33,34], where semantic interference with color judgment has significantly reduced the subject keypress task's accuracy. This interference effect reflects greater competition for attentional and cognitive resources in response to incongruent conditions. The interaction of mixed emotion priming and Stroop condition was not significant. Mixed emotions may interfere with individual cognitive control [2,4]. However, because the Stroop task is relatively easy to implement, forming an explicit representation in behavioral data may be difficult.

For EEG feature extraction, existing studies mainly focus on the frequency domain of EEG signals [21,23,35] while failing to utilize dynamic temporal changes and electrode channel information. We fill this gap using DE features incorporating time and frequency domain information. Meanwhile, DASM and RASM further contain spatial information, exploiting the relationship between different brain hemispheres to learn more informative and discriminative representations. The composite feature extraction based on time domain, frequency domain, and spatial domain information is one of the characteristics of this research. The results show that different classifiers based on the above features generally achieve good classification results, indicating that this study's feature extraction is successful.

It is worth mentioning that, unlike previous studies on pure emotion classification and recognition [21,23], the classification accuracy of mixed emotions does not show significant differences in different frequency band features. This may be related to the mixed state of emotions. When the brain is in a mixed emotional state, it may generate EEG signals with multispectral activity, potentially valuable in emotion classification. This is an important discovery that distinguishes mixed emotion recognition from pure emotion recognition, reflecting the complex and chaotic state of the brain induced by mixed emotions.

The classifiers used in this study are RF, PNN, and GRNN. The common advantage of the three classifiers is the combination of high computational efficiency and classification performance. The RF training speed is fast because the trees are independent of each other during training, so that they can be implemented in parallel. PNN is based on a Bayesian strategy feed-forward neural network, which has the advantages of easy training and fast convergence. GRNN has strong nonlinear mapping ability and learning speed and has the characteristics of self-adaptive determination of the structure. The output has nothing to do with the initial weight. There are few artificially adjusted parameters, and the network's learning mainly depends on data samples, which determines that the network can avoid the influence of subjective human assumptions on the prediction results to the greatest extent. The three classifiers are lightweight, which is helpful for the wide-scale application and promotion of the research results. Combined with different application scenarios and software systems, the classification model proposed in this study can be selectively used.

Mixed emotion recognition using EEG signals is of great interest and wide application, especially its crucial role in human-machine collaboration. For example, mixed emotions may profoundly affect cognitive flexibility and control while driving a car [36]. We can design an adaptive driver-assistance system to dynamically detect their emotional and cognitive states and react to drivers to adjust their emotions to improve driving safety. In addition, mixed emotion recognition may be applied in multiple fields, including the potential economic and social value in human-computer interaction, brain-computer interface, psychological assistance, and clinical psychotherapy.

An interesting direction for future research would be to develop multimodal frameworks for mixed emotion recognition and neural mechanism delineation. It is illustrated that one modality's weaknesses are offset by another's strengths, which can effectively increase emotion recognition accuracy and robustness compared to unimodal frameworks [37,38]. Taken together, the results of this study provide important insights into the mixed emotion recognition and priming effects on cognitive control, which are helpful for us to build a more advanced emotion monitoring and intervention system, thereby enhancing the ability to resist distraction and temptations,

execute voluntary and goal-directed behavior, and produce satisfactory performance.

***Abstract*—In EEG (Electroencephalography) based imagined speech recognition research, deep learning is gradually being applied, but has not yet achieved sufficient performance. The main reasons for this are the lack of ability to acquire generalized feature representations and the insufficient amount of training data. For the former, we propose two methods, one is a CNN-based feature extractor that introduces an attention mechanism, and the other is an improved feature extractor that introduces the inter-channel relative phase obtained from the multi-channel EEG signal as an additional spectral feature instead of a CNN-based feature extractor. For the latter, we propose a pre-training method using multi-subject EEG data to construct subject-adapted models for an imagined speech recognition task. The effectiveness of the proposed methods is verified by using an imagined speech recognition task for English phonemes, classification for English vowels and consonants. As a result, the CNN model with attention mechanism successfully improved the feature extraction capability of the CNN and achieved a classification accuracy rate of 71.9%, which are approximately 20% higher than that of the CNN only. On the other hand, a simple neural network based classifier approach using spectral features as input achieved 71.1% by using the proposed inter-channel relative phase features over the conventional relative phase features, and 75.0% by applying ensemble processing to the test data. Pre-training and subject adaptation also achieved a 6% improvement in accuracy, indicating that it is possible to mitigate the impact of insufficient training data.**

Index Terms: EEG, imagined speech, CNN, attention, transfer learning, relative phase

I. Introduction

Some patients with severe motor paralysis have paralysis of the speech organs, making communication by speech impossible. Imagined speech recognition, which recognizes words from EEG when the patient performs a speech imagining action without uttering the words aloud, has been studied as a technology that can provide such patients with an alternative means of communication to speech, and research is currently being conducted on methods to improve recognition accuracy for practical applications.

Studies on EEG (Electroencephalography) recognition and decoding are gradually making use of deep learning frameworks [1]. In addition, CNNs have been used for artifact noise removal, which is an important part of such EEG-based methods [2]. However, few studies have demonstrated the effectiveness of deep learning in the task of imagined speech recognition. In the past, methods for extracting features of phonemes, syllables, and words from brain waves during speech imagery have used analytical features such as statistics from raw signals or spectral features such as DWT and provide them as input to a discriminative model [3][4][5]. Recently, however, deep learning models have shown higher accuracy than conventional machine learning methods in the fields of speech and image recognition, and research on deep learning models is increasing in this field. Among deep learning models, there has been a particularly large amount of researches on CNNs, where feature extraction can be omitted by directly inputting multi-channel EEG signals as 2D data, as in computer vision and speech recognition applications, and CNNs specializing in EEG have also been proposed [6][7]. However, there are limited reports on the effectiveness of deep learning models for imagined speech recognition tasks, while there have been many reports on the effectiveness of deep learning models for other EEG-based classification tasks, such as event related potential (ERP) and motor imagery.

As an example of research using CNNs, Clayton et al. [8] reported that SVM had a recognition accuracy of 69.0% for the classification between English vowels and consonants for imagined speech, whereas CNN was about 49.0%, that was chance rate. In addition, Kamble et al. using machine learning methods reported results of 36.7% for the identification of EEG during imagining Spanish five vowels [9], and Cooney et al. using CNN reported results slightly lower at 35.6% [10].

This can be attributed to two problems: incomplete feature extraction capability of the trained CNN model and insufficient amount of training data. Due to the low signal-to-noise ratio of EEG signals in the speech imagery task, the features of the imagined speech are buried in noise, and a typical CNN consisting of a convolutional layer and a pooling layer is not able to acquire feature extraction well [7]. In addition, the amount of training data is insufficient for CNNs, as conventional methods are trained on one specific person's data due to the subject dependence of EEG [8].

To improve the feature extraction capability, this paper pro-

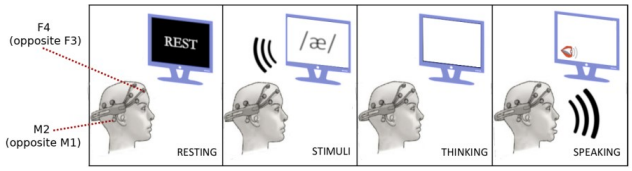

Fig. 1. Illustration of the recording procedure [8]. Participants listen to five repetitions of a phone (recorded in their own voice), then imagine speaking the phone five times (with the same rhythm), then overtly speak the phone five times.

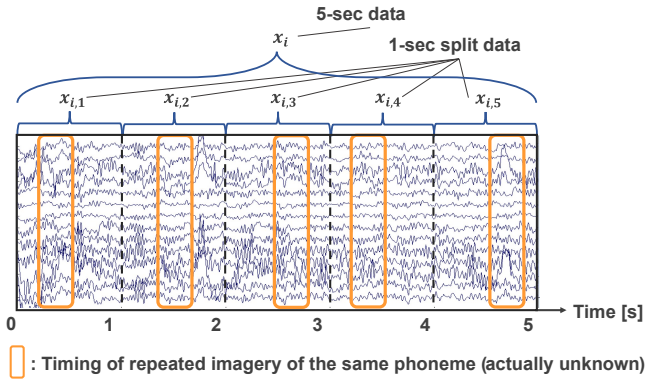

Fig. 2. Two different definitions of sample units for the "thinking" step assumed in our classification task (5-sec v.s. 1-sec split). Although it is unclear at what timing the features of EEG appear during imaging, we assume that each features imagining 5 times repeated within the 5-sec data would manifest within 1 second.

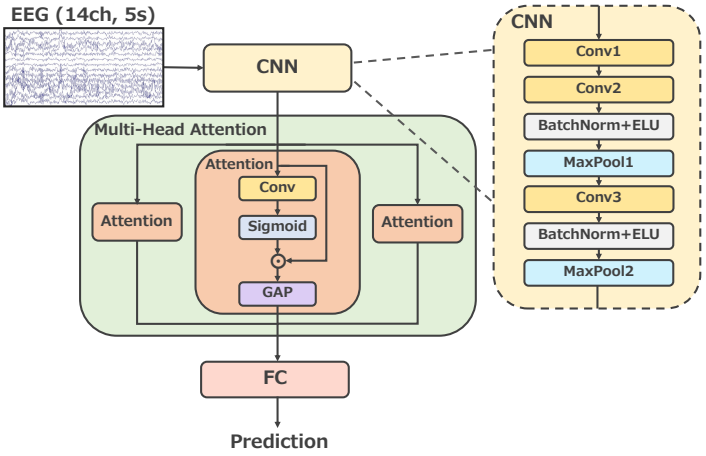

Fig. 3. Proposed classifier with attention-based CNN. CNN:Convolutional Neural Network, GAP:Global Average Pooling, FC: Fully Connected Layer.

TABLE I
PARAMETERS OF THE CNN PART

Layers	Parameters
Conv1	n_filters = 5, filter_size = (1, 10), stride = 1
Conv2	n_filters = 50, filter_size = (ch_n, 1), stride = 1
MaxPool1	kernel_size = (1, 3), stride = 3
Conv3	n_filters = 15, filter_size = (1, 5), stride = 1
MaxPool2	kernel_size = (1, 3), stride = 3

poses two methods: one is to introduce an attention mechanism into the CNN-based feature extractor, and the other is to use an improved feature extractor that introduces as an additional spectral feature inter-channel relative phase obtained from the multi-channel EEG signal instead of a CNN-based feature extractor. Attention is a mechanism that automatically learns which of the intermediate feature outputs of a deep learning model are important, and our intention in this study is to input the features output by the CNN into the attention mechanism to emphasize the features of recalled speech that are expected to be observed only for a short period of time. To compensate for the lack of ability in feature representation learning, we also propose a method to improve the spatial feature extraction of EEG with relative phase feature, which is an improved method of our previous work [11]. To cope with the lack of training data, pre-training and subject adaptation are proposed. The amount of insufficient training data is compensated by pre-training with multiple subjects' data, and the model is trained again with the target subject's data to cope with subject dependence. The effectiveness of these methods is verified in this study.

II. DATASET

The dataset used in this study [8] contains EEG data from 21 subjects using a commercial-grade light-weight mobile headset EEG device (Emotiv EPOC+). The EEG signals were recorded using the 14 channels with sampling frequency of 256Hz. There are 160 samples for each subject, and each sample is the EEG of a trial consisting of four steps ("resting", "stimulus", "thinking", and "speaking") of 5 seconds each (Fig. 1). During the "stimulus" step, a randomly selected English phoneme is presented repeatedly for 5 times. Next, in the "thinking" step, subjects are instructed to imagine the same phoneme being repeated five times as it was played in the "stimulus" step. There are 16 English phonemes to be imagined (4 vowels and 12 consonants), with 10 sample trials per phoneme recorded for each subject. Only the 5-second portion of the "thinking" step of the dataset is used in our experimental task. Also, since this dataset contains subjects with significant noise contamination, only data from 12 subjects, excluding those, are used.

In this study, each trial in this dataset is treated in two different ways (Fig. 2). In the experiment using a convolutional neural network (section III-A), the EEG data imagined five times in 5 second is used as input as it is. Also, in the experiment using spectral features (section III-C), each trial data is divided into 5 parts for increasing the training samples. These divided parts are treated as separate samples for training and classification. Although it is unclear at what timing the features of EEG appear during imaging, we assume that each features imagining 5 times repeated within the 5-sec data would manifest within 1 second.

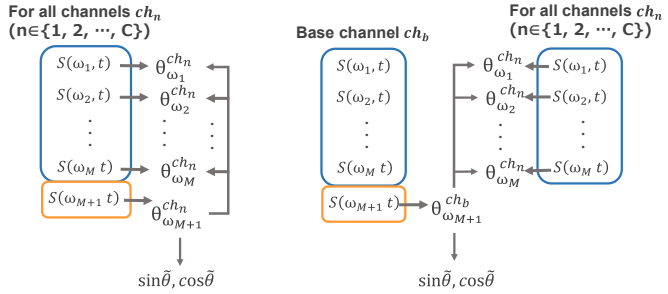
III. METHOD

A. Attention-Based CNN

Attention is an architecture that is used for deep learning models and allows them to learn which features are important and highlight them among the intermediate outputs of the deep learning model [12]. In this study, an attention is placed after CNN to capture the moment of occurrence of the imagined speech features in the entire EEG features. The structure of the model used in this study is shown in Fig. 3. The CNN part that plays the role of Encoder is based on the CNN structure used in the previous study [7]. In Ref. [8], they reported a loss of accuracy due to insufficient number of training samples, so we made adjustments to the number of layers and the parameters of each layer. The details of the configuration of the CNN part are shown in Table I. Convoluting the input 2D EEG data consisting of electrode dimension (14 channels) and time dimension (5 seconds) is performed by three convolution layers and two pooling layers. Then, an attention is placed after the last pooling layer.

The model for the attention block in Fig. 3 is based on [13] and composed of a convolutional layer with a filter size of 1×1, a sigmoid layer, and an average-pooling layer. First, the attention block generates attention mask $\mathbf{M}$. Let $\mathbf{M}$ be the attention mask for a certain filter of the final convolutional layer, the attention mask $\mathbf{M}$ is obtained as follows:

$$\mathbf{M} = \sigma(f^{1\times1}(\mathbf{F}^{H\times W})) \tag{1}$$



where $\mathbf{F}^{H\times W}$ is the input feature (H:14 ch, W:1280 (5-sec×256 Hz)), $f^{1\times1}$ is the convolution with filter size 1×1, and σ is the sigmoid function. $\mathbf{M}$ has the same $H \times W$ size as the input features, and update with learning to highlight the important feature. Then, important features are highlighted as:

$$\mathbf{F'}^{H\times W} = \mathbf{F}^{H\times W} \odot \mathbf{M} \tag{2}$$

Finally, global average pooling is applied to compress each feature map to a size of 1×1. In addition, this study also employs a structure called multi-head attention [14]. Assuming the number of attention heads is denoted as H_{Att} and the number of filters as C, the $H_{Att} \times C$ features are passed to the final linear layer, that is, fully connected (FC) layer.

B. CNN Model Pre-training and Subject Adaptation

We pre-train the CNN model with data of multiple subjects to compensate sufficient training data and fine-tune (FT) it with the data of a target subject for subject adaptation. When subject $n(1 \leq n \leq N)$ is selected from the N subjects dataset $\{X_1, \cdots, X_N\}$, the target domain (subject adaptation) dataset is defined as $D_{\mathbf{T}} = \{X_n\}$. The source domain (pre-training) dataset is the combination of all subject data except for the target subject and defined as $D_{\mathbf{S}} = \cup_{i\neq n}\{X_i\}$. The pre-training task and subject adaptation task are set to the same classification (vowel or consonant). In this study, all parameters of the pre-trained model is not fixed in FT. Subject adaptation allows the pre-trained model to take care of the dependence on the target subject.

(a) Intra-channel(fixed base-freq) (b) Inter-channel with fixed base-channel & freq (ICRP_FF)

Fig. 4. Relative phase features of EEG signals (conventional methods). $(M + 1)$ is the base frequency bin.

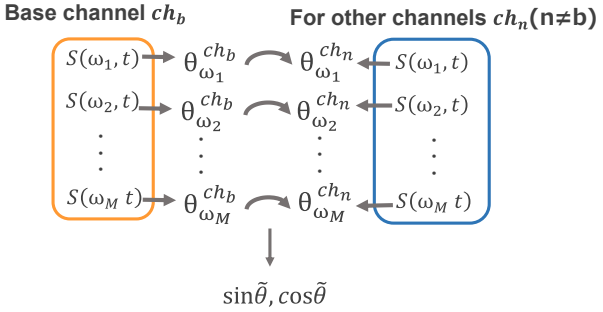


Fig. 5. Proposed inter-channel relative phase within the same frequency bins (ICRP_SF) of multi-channel EEG signals

C. Neural Network Using Spectral Features

We propose a classification method using improved front-end feature extraction, as a comparison to the attention-based CNN model. In conventional speech signal processing, Mel-Frequency Cepstral Coefficients (MFCC) are primarily used as the feature representation. However, MFCC only utilizes the amplitude spectrum and ignores the phase spectrum of the obtained spectrogram. In Ref. [15][16], the effectiveness of phase has been shown in speaker classifier modeling. In the feature representation of multi-channel EEG signals, the relative phase feature is considered effective in extracting spatial feature representation.

For per-channel EEG feature extraction, the amplitude and phase spectra are computed for each frequency bin in the analysis interval using the Discrete Fourier Transform (DFT). This can be expressed as follows:

$$S(\omega, t) = A(\omega, t) \times e^{j\theta(\omega,t)} \tag{3}$$

Here, $A(\omega, t)$ and $\theta(\omega, t)$ represent the amplitude spectrum and the phase spectrum. The phase spectrum depends strongly on the position of window, so we use the relative phase. In the case of relative phase, the phase of a certain frequency component is used as a reference, and the phases at other frequencies are calculated relative to this reference phase using the following equation:

$$\tilde{\theta}(\omega', t) = \theta(\omega', t) - \frac{\omega'}{\omega}\theta(\omega, t) \tag{4}$$

TABLE II
FEATURE REPRESENTATIONS COMPARED FOR SIMPLE NEURAL NETWORK CLASSIFIER SETTING (FEATURE "CONV-RP" REPRESENTS ONE OF THE TWO CONVENTIONAL RELATIVE PHASE FEATURE EXTRACTION METHODS SHOWN IN FIGURE 4)

Features	Input Dimensions
Amplitude	140 (14ch×5 dim×2(mean,std))
CONV-RP	280 (14ch×5 dim×2(sin, cos)×2 (mean,std))
ICRP_SF	260 (13ch×5 dim×2(sin, cos)×2 (mean,std))
Amplitude + CONV-RP	420 (140 + 280)
Amplitude + ICRP_SF	400 (140 + 260)

To address the issue of phase discontinuity, we utilize the corresponding coordinate values $[\cos\tilde{\theta}, \sin\tilde{\theta}]$ instead of $\tilde{\theta}$. In previous studies on imagined speech recognition, Sakai et al. conducted research using relative phase information. They set the reference frequency as one higher order than the frequency range of interest and utilized the relative phase of the lower-order 5 dimensions (8 to 40 Hz). As a result, they reported an accuracy of 51.5% in a binary classification task using only relative phase (Fig. 4a) and 58.5% using amplitude spectrum and relative phase features together [11]. Sakai et al. also proposed inter-channel relative phase with fixed base channel and base frequency (Fig. 4b) to capture the phase difference between each channel and reported minor improvement.

In this study, our intention is to extend the phase feature representation to capture the spatial features of multi-channel EEG signals, that is, correlation between channels. Therefore, we focus on the inter-channel relative phase within the same frequency bins (ICRP_SF, see Fig. 5). As a baseline for the EEG classifier, we compare with amplitude and phase features and investigate the effectiveness of combining these features. Let designate ch_b as the base channel and ch_n as the channel for which the relative phase is calculated. The base frequency is identical to the frequency used for calculating the relative phase. Therefore, we can express it as follows, using the formula for relative phase (Eq. 4):

$$\begin{aligned}\tilde{\theta}^{ch_n}(\omega', t) &= \theta^{ch_b}(\omega', t) - \frac{\omega'}{\omega}\theta^{ch_n}(\omega, t) \\ &= \theta^{ch_b}(\omega, t) - \theta^{ch_n}(\omega, t)\end{aligned} \tag{5}$$

It is a simple phase subtraction in each frequency dimension. Therefore, the case $ch_b = ch_n$ is excluded (because the relative phase is zero). We calculate DFT with a window length of 125ms and utilize the average and standard deviation along the time dimension of the lower-order 5-dimensional (8 to 40 Hz) amplitude and phase spectra as feature parameters. Table II shows a comparison of the types of feature parameters and their dimensions. When calculating the relative phase, we exclude the target channel if it is the same as the base channel (calculated relative phase becomes 0). This features is given as input to a linear layer with 100 nodes in the hidden layer for classification.

IV. RESULTS

We examined the recognition accuracy of a binary classification task, in which the task is to recognize from EEG whether an imagined phoneme is a vowel or a consonant. Although there were originally 160 samples per subject, the number of samples for consonants was reduced to 40, the same as vowels, for a total of 80 samples, in order to eliminate class bias (consonants:vowels = 120:40 → 40:40). The number of multi-head attention H_{Att} was set to 5 in our experiments since preliminary experiments showed the best performance. However, almost the same performance was obtained with $H_{Att} = 1$, indicating that multi-head does not significantly affect the performance of this experimental task.

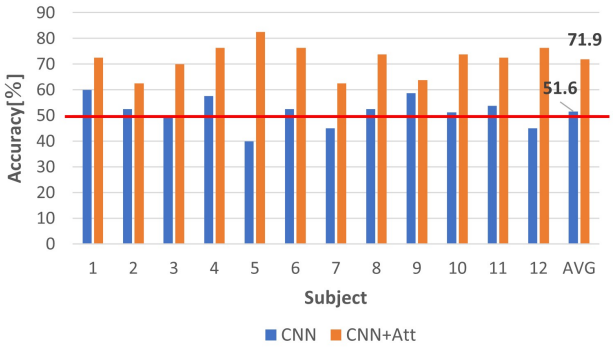

Fig. 6. Classification accuracy of the English phoneme by the typical CNN and the attention-based CNN (red line: chance rate)

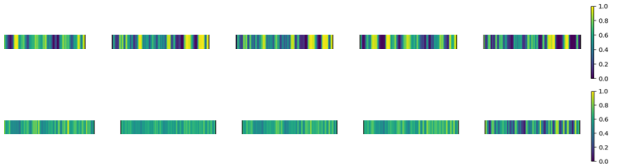

Fig. 7. Example of attention mask generated for correct (top) and incorrect (bottom) predicts

A. Attention-Based CNN

In the baseline CNN and CNN+Attention models, raw EEG data is utilized. Therefore, the input consists of 2D data with dimensions of 14 channels × 1280 (256Hz × 5s). Training and evaluation were performed independently for each subject, and 5-fold cross validation was applied.

The results of vowel and consonant classification using the English phoneme dataset from subjects 1 to 12 with the baseline CNN and the CNN+Attention models are shown in Fig. 6. The CNN+Attention model outperforms the baseline CNN model in terms of classification accuracy for all subjects. In most subjects, the CNN+Attention model achieves a classification accuracy that is approximately 10-20% higher than the baseline CNN model (in other words, the error reduction rate is approximately 20-40%). Notably, even though the baseline CNN falls below 50% accuracy for subject 5, the CNN+Attention model achieves an accuracy of over 80%. Finally, Fig. 7 shows the results of visualizing the attention masks generated in the attention mechanism for correct and incorrect responses. It can be seen that there are repeated

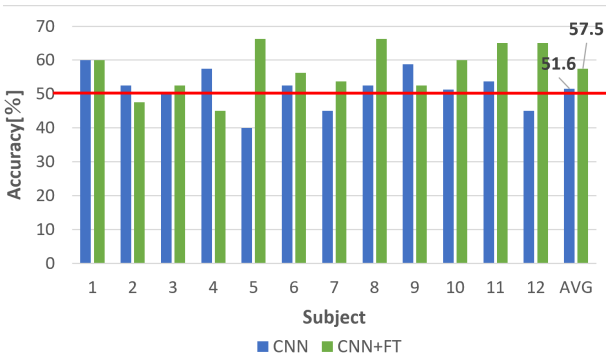

Fig. 8. Classification accuracy of the English phoneme by the CNN with pre-training+subject adaptation (FT) and the CNN without them(red line: chance rate)

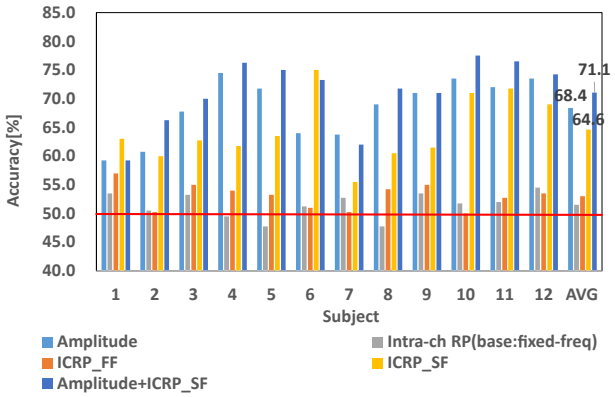

Fig. 9. Accuracy of classification by the NN model for each subject when using the amplitude spectrum, relative phase and their combination. In conventional inter, intra-channel relative phase, the fixed base frequency is the 6th bin of the base electrode. The base electrode for inter-channel relative is selected as the one that was best on average for the subjects.

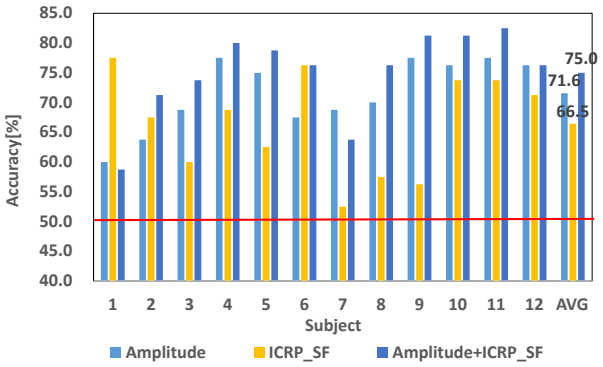

Fig. 10. Accuracy of **ensemble classification** by the NN model for each subject when using the amplitude spectrum, relative phase and their combination. The base electrode for inter-channel relative phase is selected as the one that was best on average for the subjects.

highlighted areas in the attention mask if the prediction is correct. On the other hand, the values are not repeatedly highlighted if the prediction is wrong. From this, it can be said that the attention mechanism is functioning to make correct predictions.

B. CNN model Pre-training + Subject Adaptation

In the case of conducting pre-training with data from multiple subjects, 11 out of the 12 subjects (excluding the target subject) are used for pre-training (880 samples in total, 11 subjects $\times$ 80 samples). After pre-training with the combined data from 11 subjects, the 5-fold cross validation procedure is applied for the binary classification task and the model with the lowest loss is used.

The results of the classification of the English phoneme dataset by the baseline CNN and the CNN with pre-training+subject adaptation (CNN+FT) are shown in Fig. 8. Assuming that the result is chance rate when the accuracy is in the 45-55% range, three subjects (2, 3, 7) have chance rate, but the CNN+FT model outperformed the baseline CNN in the other six of the remaining nine subjects (5, 6, 8, 10, 11, 12). It can be inferred that the increase in the number of training samples by 11 times has contributed to this improvement. In terms of average classification accuracy, applying FT leads to an improvement of approximately 6% (in other words, error reduction rate is 12%). Based on these results, it can be concluded that the proposed approach of pre-training and subject adaptation is effective, and it can mitigate the impact of insufficient training data.

C. Neural Network Using Spectral Features

In the first experiment for neural network classification using spectral features, each trial data which the subject imagined 5 times repeatedly in 5 seconds is divided into 5 parts for increasing the training samples. These divided parts are treated as separate samples for training and classification. Therefore, it is important to note that the sample sizes are different compared to the performance evaluation of the CNN-based models described earlier. The training and evaluation of the model employed 5-fold cross validation, using the data of each subject independently.

Fig. 9 shows the classification accuracy using the amplitude spectrum, the conventional relative phase features [11] ("Intra-channel (fixed base-freq)" and "ICRP_FF" in Fig. 4), the relative phase proposed in this study (Fig. 5), and the combined use of the relative phase and amplitude spectrum. Here, the base electrode is selected as the one that was best on average for the subjects. From the comparison of the relative phase between the conventional and proposed methods, it can be observed that the relative phase used in this study achieved 64.6% accuracy, significantly surpassing the conventional method. Furthermore, it is evident that the proposed method outperforms the amplitude spectrum in participants 1 and 6. On average across subjects, the relative phase exhibits a difference of approximately 4% in classification accuracy compared to the amplitude spectrum. This suggests that relative phase captures EEG features to a slightly lesser extent than amplitude features. In addition, the combined use of the amplitude spectrum and proposed relative phase shows improved accuracy compared to

TABLE III
COMPARISON OF THE EFFECTS WITH AND WITHOUT DATA DIVISION

	5-sec data	1-sec split data
CNN (raw)	51.6	50.3
CNN (raw)+Att	71.9	56.5
NN (Amp+ICRP_SF)	52.9	71.1

using the amplitude spectrum alone for all subjects except 1, 7, and 9. Notably, the subject 4 achieved a classification accuracy of approximately 76.5% using the combined features. Despite using only statistical simple features as inputs to the neural network, the model achieved performance comparable to the aforementioned attention-based CNN model which classified each sample by using 5 seconds.

Next, in the inference stage, the classification results were evaluated using a ensemble scheme (majority vote) based on dividing the 5-second trial samples that were imagined 5 times into 5 segments and using each segment classification. The results of this classification are presented in Fig. 10. It is the same as the CNN and CNN+Attention models in that the entire 5s is used for classification prediction. The experiment is unchanged in that 1s of data divided into 5s is given as input in the training stage, 5-fold cross validation is applied and the data is used for each subject independently. From the results, it can be observed that by utilizing both amplitude and phase information, classification accuracies of 80% or higher were achieved for subjects 4, 9, 10, and 11. Furthermore, a classification accuracy of 75% was achieved on average for all subjects and the accuracy is improved by 2-4% compared to the case where no ensemble process (in other words, the error reduction rate is 5-13%). However, it is important to note that these comparisons have different experimental designs (number of test samples) in the evaluation.

D. Comparison

1) Comparison of the effects with and without data division: In the CNN and CNN+Attention models, the 5-second raw signal, which was imagined five times, was directly used as input. On the other hand, in the experiments using spectral features, the trial data was divided into five equal parts and treated as separate samples. In this point of view, we compare the difference in classification accuracy with and without data division for each of the methods. The results are shown in Table III. In the case of CNN+Attention, it is observed that the classification accuracy is higher when data division is not performed. This suggests that the Attention mechanism is effective for the data that is repeated imagery. Furthermore, in the case of spectral features, it is observed that data division improves the classification accuracy. A possible reason for the poor classification accuracy when data division is not applied is that the speech imagery features that appear in a short period of time are buried because we extract feature as mean statistic for entire segment, and the feature might be influenced remarkably by non-imagined parts.

TABLE IV
AVERAGE CLASSIFICATION ACCURACY FOR EACH METHOD IN THE TWO-CLASS CLASSIFICATION OF THE ENGLISH PHONEME DATASET[%]. RP:RELATIVE PHASE, FT:FINE TUNING, ICRP_SF:PROPOSED RELATIVE PHASE, *:1-SEC SPLIT DATA WERE USED

Model (input)	Accuracy[%]
SVM (statistical feature)[8]	69.0
CNN (raw)[8]	49.0
CNN (raw)	51.6
CNN (raw)+FT	57.5
CNN (raw)+Att	71.9
CNN(raw)+Att+FT	**75.3**
NN (Amp)*	68.4
NN (Intra-ch RP base 6th dim)[11]*	51.5
NN (Amp+Intra-ch RP base 6th dim)[11]*	58.5
NN (ICRP_SF)*	64.6
NN (Amp+ICRP_SF)*	71.1
NN (Amp)+test data ensemble	71.6
NN (ICRP_SF)+test data ensemble	66.5
NN (Amp+ICRP_SF)+test data ensemble	**75.0**

2) Comparison with previous research: The average classification accuracy of the method proposed in this study and the previous studies [8] and [11] for the same database are summarized in Table IV. Although the experimental conditions were different, the classification accuracy of CNN models with attention (CNN+Att, CNN+Att+FT) exceeded 70% in both cases, surpassing the classification accuracy of 69.0% achieved by SVM in [8]. The classification with spectral features in this study achieved a classification accuracy of 75.0% by the test data ensemble process, which is the highest accuracy for classification with handcrafted features using this data set. These show the effectiveness of the two proposed classification methods.

V. CONCLUSIONS

In this study, we investigated methods to solve two problems related to deep learning in EEG-based imagined speech recognition. To address the lack of feature extraction capability of CNNs for imagined speech, we showed that the attention mechanism is capable of capturing repeated imagined speech features. For the lack of training data, pre-training with multiple subject data (excluding the target subject's) and subject adaptation with specific subject data were shown to be effective for improvement. In addition, we proposed the classification model using both the inter-channel relative phase and the amplitude spectrum features. The classification accuracy in this case reached 75%, which was the highest for classification using handcrafted features in the dataset used. As a future work, it is possible to try to further improve classification accuracy by using proposed spectral features as input for the attention-based CNN model.

***Abstract*—Because neuronal networks are intricate systems composed of interconnected neurons, their control poses challenges owing to their nonlinearity and complexity. In this paper, we propose a method to design control input to a neuronal network to manipulate the firing patterns of modules within the network. We propose a methodology for designing a control input based on temporal deep unfolding-based model predictive control (TDU-MPC), a control methodology based on the deep unfolding technique actively investigated in the context of wireless signal processing. During the method development, we address the unique characteristics of neuron dynamics, such as zero gradients in firing times, by approximating input currents using a sigmoid function. The effectiveness of the proposed method is confirmed via numerical simulations. In networks with 15 and 30 neurons, the control was achieved to switch the firing frequencies of two modules without directly applying control inputs. This study includes a tailored methodology for networked neurons, the extension of TDU-MPC to nonlinear systems with reset dynamics, and the achievement of desired firing patterns in neuronal networks.**

I. Introduction

The brain, a highly complex organ, consists of a vast network of interconnected neurons. When an individual neuron within the network generates an electrical impulse called firing, neighboring neurons receive an electrical influx that serves as a stimulus to trigger their firing. This phenomenon propagates throughout the entire network and contributes to the complex pattern of the firing dynamics in the brain. Hence, the brain exhibits a wide range of electrically active patterns and dynamic behaviors that account for its remarkable capabilities and functions [1].

Studies focused on brain dynamics control [2] have the potential to yield significant advancements in the enhancement of human cognitive function and the performance of brain–machine interfaces and artificial nerves. For example, advancements in brain dynamics control are expected to pave the way for the development of novel therapies for psychiatric disorders [3]. In addition, a greater degree of seamless communication between the human brain and external devices can be achieved by precisely controlling the firing patterns of neurons to optimize the brain–machine interfaces [4]. The prospect of using brain dynamics control to improve human welfare, both in terms of cognitive enhancements and psychiatric disorder treatments, demonstrates the potential of such research [2].

Owing to the complex nature of a neuronal network, controlling its firing pattern is challenging [5]. A neuron is often modeled as a nonlinear dynamical system characterized by abrupt jumps in membrane potential as neurons are fired [6]. Such nonlinearity adds a layer of complexity to the control problem [7]. In addition, a neuronal network as a whole represents a large system consisting of several interconnected neurons with complex interactions. Network size further complicates control efforts by introducing a large number of variables and inter-dependencies, which are to be considered. Addressing these challenges requires developing sophisticated control strategies capable of accommodating the unique characteristics and complexities inherent to neuronal network dynamics.

In this study, we aim to develop a methodology for designing control input currents to effectively manipulate the firing frequency of multiple modules within a network, even when neurons not belonging to the modules are under control. Therefore, we employed temporal deep unfolding-based model predictive control (TDU-MPC) introduced in [8] as a control methodology. TDU-MPC offers solutions for tackling optimization problems that arise during each step of MPC by employing emerging technologies, such as deep unfolding [9]–[13]. Deep unfolding involves the temporal unfolding of the mathematical model of a control object by treating it as a feed-forward network. Using backpropagation, the control inputs at each instant of time step are acquired via learning, and the iterative process is repeated for each step.

Although TDU-MPC has been recognized for its effectiveness in the control of nonlinear dynamical systems [8], the dynamic characteristics of neurons pose challenges. The main challenge lies in the fact that once a neuron model is discretized, the firing times of the neurons can have a zero gradient with respect to the control, as has been observed by our preliminary experiments. This property of the gradient complicates the process of learning control inputs because TDU-MPC relies on deep learning techniques. To overcome such hurdles, we developed an approach to approximate the input current of neighboring neurons by means of a sigmoid function, which enabled us to avoid the aforementioned problem of zero gradient.

The contributions of this study are summarized as follows. First, the paper proposes the methodology for designing control input to neuronal networks to achieve a desired firing pattern of modules within the networks. Second, unlike other methodologies primarily focused on single neurons [5], our methodology is tailored to *networks* of neurons. Third, the applicability of TDU-MPC can be extended to include nonlinear systems exhibiting reset dynamics.

This paper is organized as follows: Section II states the problem studied in this paper, while Section III proposes a method for solving the control problem. Section IV presents the results of numerical simulations. Finally, the paper is concluded in Section V.

II. Problem Statement

In this section, we formally state our problem of controlling the neuronal dynamics. In Subsection II-A, we state our model of neuronal networks. Subsequently, in Subsection II-B, we state the control problem addressed in this paper.

A. Neuronal Network

In this subsection, we state the model of a neuronal network. Let $\mathcal{G} = (\mathcal{V}, \mathcal{E})$ denote the directed graph representing the connectivity of the neuronal network. The node set $\mathcal{V} = \{1, \dots, N\}$ represents the set of neurons, while the edge set $\mathcal{E}$ represents the connectivity among the neurons. For each $i \in V$, $\mathcal{N}_i$ denotes the set of in-neighbors of node i. Under this notation, we assume that when a neuron in $\mathcal{V}_i$ fires, the neuron i receives a current.

The type of firing neuron determines the effect on its neighboring neurons. For this study, we assume, as is common in the literature, that neurons are divided into two types of neurons: excitatory neurons and inhibitory neurons. The set of the former neurons is denoted by $\mathcal{V}_{\text{ex}}$, while the latter is denoted by $\mathcal{V}_{\text{in}}$. An excitatory neuron induces a positive current I_{ex} to its neighbors, while an inhibitory neuron induces a negative current I_{in}.

We assume that each neuron $i \in \mathcal{V}$ follows the Izhikevich model [6] described by the differential equation

$$\dot{v}_i(t) = 0.04v_i^2(t) + 5v_i(t) + 140 - u_i(t) + I_i(t), \quad (1)$$

$$\dot{u}_i(t) = a(bv_i(t) - u_i(t)) \quad (2)$$

with the reset dynamics described by

$$\begin{bmatrix} v_i(t^+) \\ u_i(t^+) \end{bmatrix} = \begin{bmatrix} c \\ u_i(t) + d \end{bmatrix}, \quad \text{if } v_i(t) \geq 30. \quad (3)$$

For this study, we assume that a neuron i fires at time t if $v_i(t) \geq 30$. The real numbers a, b, c, and d in the dynamical model are considered dimensionless parameters. By varying the values of these dimensionless parameters, a rich variety of neuronal behaviors, including regular spiking, bursting, and fast spiking, can be achieved. Therefore, the Izhikevich model is extensively used to study and replicate various types of neuronal activity seen in different regions of the brain.

In the differential equations (1) and (2), the scalar variable $v_i(t)$ represents the membrane potential of neuron i at time t, while $u_i(t)$ represents the value of the membrane recovery variable of neuron i at time t. Further, $I_i(t)$ represents the current input to neuron i and is assumed as

$$I_i(t) = I_{i,\text{control}}(t) + I_{i,\text{internal}}(t),$$

where $I_{i,\text{control}}(t)$ is the control input signal that we need to design, and $I_{i,\text{internal}}(t)$ represents the inter-network current induced by firing events of neurons. In this paper, for simplicity, the inter-network current is supposed to be of the additive form defined as

$$I_{i,\text{internal}}(t) = \sum_{j \in \mathcal{N}_i} I_{ij}(t), \quad (4)$$

where $I_{ij}(t)$ represents the current input from neuron j to neuron i and is assumed to be of the form

$$I_{ij}(t) = \begin{cases} I_{\text{ex}}, & \text{if neuron } j \text{ fired in } [t-\tau, t] \text{ and } j \in \mathcal{V}_{\text{ex}}, \\ I_{\text{in}}, & \text{if neuron } j \text{ fired in } [t-\tau, t] \text{ and } j \in \mathcal{V}_{\text{in}}, \\ 0, & \text{otherwise}, \end{cases} \quad (5)$$

where $\tau > 0$ is a parameter.

B. Control Objective

For this study, we consider the selective and dynamic enhancement problems caused by the firing activity of a specified module of neurons. Specifically, the network is assumed to consist of three modules, with stronger within-module connectivities than inter-module connectivities. Further, we assume that the control current is applied only to the neurons within a specific module. We consider a closed-loop control of the neurons; therefore, we assume that we can use the membrane potentials $v_i(t)$ for all $i \in \mathcal{V}$ to determine the input current $I_{i,\text{control}}(t)$ for $i \in \mathcal{V}_{\text{control}}$. Under this supposition, our objective is to control the firing frequency of other modules.Specifically, we aim to design the following firing pattern: From the initial to a pre-specified time, a module $\mathcal{V}_1 \subset \mathcal{V}$ fires frequently while another module $\mathcal{V}_2 \subset \mathcal{V}$ exhibits low firing activities. Thereafter, the module $\mathcal{V}_2$ should fire frequently, while module $\mathcal{V}_1$ fires less frequently.

Thus, the aforementioned control problem can be formally stated as follows:

Problem 1. *Assume that the set $\mathcal{V}$ of neurons is divided into disjoint subsets $\mathcal{V}_{control}$, $\mathcal{V}_1$, and $\mathcal{V}_2$. Assume*

$$I_{i,control}(t) = 0 \text{ for all } i \in \mathcal{V}_1 \cup \mathcal{V}_2.$$

Let T_s and T_e be real numbers satisfying $0 < T_s < T_e$ and define intervals $\mathcal{I}_1$ and $\mathcal{I}_2$ by

$$\mathcal{I}_1 = [0, T_s], \ \mathcal{I}_2 = [T_s, T_e].$$

For a subset $\mathcal{W}$ of $\mathcal{V}$ and a time interval $\mathcal{I}$, define

$$f_{\mathcal{W},\mathcal{I}} = \sum_{i \in W} \text{(number of fires of neuron } i \text{ on } \mathcal{I}).$$

Construct a feedback controller of the form

$$I_{i,control}(t) = K_i(v_1(t), \dots, v_N(t)) \quad (6)$$

for all $i \in \mathcal{V}_{control}$ such that the objective function

$$(f_{\mathcal{V}_1,\mathcal{I}_1} - f_{\mathcal{V}_2,\mathcal{I}_1}) + (f_{\mathcal{V}_2,\mathcal{I}_2} - f_{\mathcal{V}_1,\mathcal{I}_2}) \tag{7}$$

is maximized.

Remark 1. *In the practical implementation of the control rules* (6)*, real-time calculation of the control input $I_{i,control}$ is preferred. However, in this research, real-time capability is not a requirement, and its realization is left for future investigation. Similarly, the assumption of membrane potential observability, though challenging in practice, aligns with existing practice in the literature (see, e.g., [5]).*

Because Problem 1 requires the control of a nonlinear reset system [14], a standard and effective solution involves the use of model predictive control (MPC) [15]. MPC is a type of feedback control method that aims to achieve optimal control by predicting the behavior of a controlled object at a fixed interval in the future from the current time. In MPC, the controlling input at each instance is determined by solving an optimization problem. The optimization problem consists of a mathematical model of the control target, a cost function obtained from the outputs in the prediction horizon, and constraints. Owing to its effectiveness in optimizing control inputs, handling constraints, and dealing with nonlinear systems, MPC has various applications, including process control, energy management, and automotive systems. Among various approaches available for performing MPC, we chose to use TDU-MPC [8] for this study. TDU-MPC offers several advantages such as easy implementation and the ability to find high-quality solutions.

III. Proposed Method

In this section, we propose a method to solve Problem 1 leveraging TDU-MPC. In Subsection III-A, we present an overview of TDU-MPC, while Subsection III-B presents the proposed methodology for solving Problem 1.

A. TDU-MPC

To understand TDU-MPC, we begin by reviewing deep unfolding [9]–[13] that TDU-MPC is built upon. Deep unfolding is a method for tuning the parameters of iterative algorithms using techniques from deep learning. In deep unfolding, a given iterative algorithm is first unfolded in the time direction and considered a feed-forward network with the number of layers equal to the number of iterations. Next, the parameters of each step of the iterative algorithm are embedded as learnable parameters in the network and tuned via backpropagation and stochastic gradient descent methods. Incremental learning, a widely used technique, is adopted to avoid gradient loss that can occur during parameter learning.

TDU-MPC has been proposed as a method to overcome the disadvantages of existing methodologies for performing MPC. In this subsection, we provide a brief overview of TDU-MPC, considering a discrete-time dynamical system such as

$$\Sigma : x[k+1] = f(x[k], u[k], w[k]),\ k = 0, 1, 2, \dots$$

where x, u, and w represent the state variable, control input, and disturbance signal, respectively. In TDU-MPC, the system is considered as an iterative algorithm, and the control input is regarded as a learnable parameter.

Specifically, we first make the feed-forward network with T layers. Each layer is the state x at each instance of time of unfolded T-step state transitions in the temporal direction. Next, the control inputs at each instance can be learned using deep learning techniques as in deep unfolding. The disturbances at each instance of time are used as data, and learning is performed using the objective function of the optimization problem in MPC as the cost function. Thereafter, the control input minimizing the following objective function

$$\sum_{\ell=0}^{T-1} p_\ell(x[k+\ell], u[k+\ell]) + p_T(x[k+T])$$

is designed using the aforementioned scheme. In Fig. 1, we illustrate a schematic picture illustrating TDU-MPC. For the details of TDU-MPC, readers are referred to [8].

B. Discrete-time Model

As described in the previous subsection, TDU-MPC is a methodology for controlling discrete-time dynamical systems, while Problem 1 involves a continuous-time model. Therefore, for applying TDU-MPC to Problem 1, the dynamics presented as (1)–(3) and the objective function (7) must be appropriately discretized.

Let $\Delta t > 0$ denote the time step for discretization. For this study, we discretized the differential equations (1) and (2) as

$$v_i[k+1] = \begin{cases} v_i[k] + (0.04v_i^2[k] + 5v_i[k] \\ \qquad +140 - u_i[k] + I_i[k])\Delta t, & \text{if } v_i[k] < 30, \\ v_i[k] - (30 - c), & \text{otherwise} \end{cases} \tag{8}$$

and

$$u_i[k+1] = \begin{cases} u_i[k] + (a(bv_i[k] - u_i[k]))\Delta t, & \text{if } v_i[k] < 30, \\ u_i[k] + d, & \text{otherwise,} \end{cases} \tag{9}$$

where the input current

$$I_i[k] = I_{i,\text{control}}[k] + I_{i,\text{internal}}[k]$$

consists of the control signal $I_{i,\text{control}}[k]$ to be designed and the input current $I_{i,\text{internal}}[k]$ resulting from firing events at neighbor neurons. As in the continuous-time case, we say that a neuron i fires at time k if $v_i[k] \geq 30$.

Similar to (4), we assume the input current $I_{i,\text{internal}}[k]$ of the form

$$I_{i,\text{internal}}[k] = \sum_{j \in \mathcal{N}_i} I_{ij}[k],$$

where $I_{ij}[k]$ represents the current input from neuron j to neuron i and is given by

$$I_{ij}[k] = \begin{cases} S(v_j[k])I_{\text{ex}}, & \text{if } j \in \mathcal{V}_{\text{ex}}, \\ S(v_j[k])I_{\text{in}}, & \text{otherwise} \end{cases} \tag{10}$$

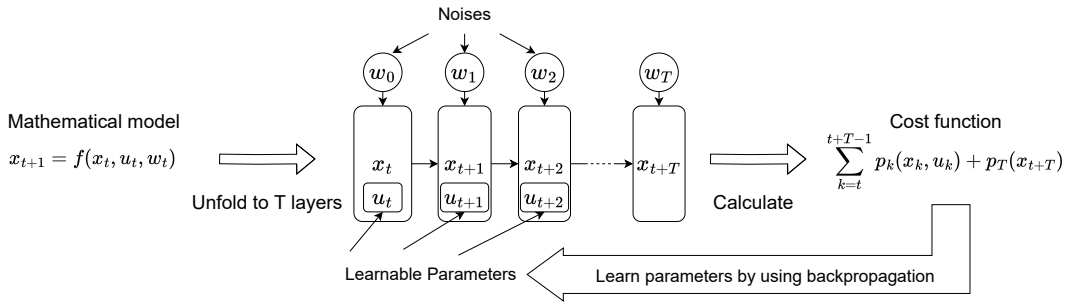

Fig. 1: Schematic picture of temporal deep unfolding-based model predictive control (TDU-MPC)

in which the introduced coefficient $S(v_j[t])$ serves the purpose of introducing a soft-threshold and is defined as

$$S(v_j[k]) = \frac{1}{1 + \exp(-\sigma(v_j[k] - 20))}. \tag{11}$$

One of the main reasons for introducing the soft-threshold mechanism is to ensure the differentiability of the objective function. To effectively perform deep learning and deep unfolding, the differentiability of the objective function is an important requirement. Conversely, the differentiability of the cost function with respect to the input current $I_{i,\text{control}}$ to be designed cannot be guaranteed without soft-thresholding. Therefore, introducing the soft-thresholding mechanism is necessary. In fact, we confirmed through our preliminary experiments that for a system model with an inter-node input current of the form (5), TDU-MPC often fails to yield an effective control input signal.

C. Cost Function

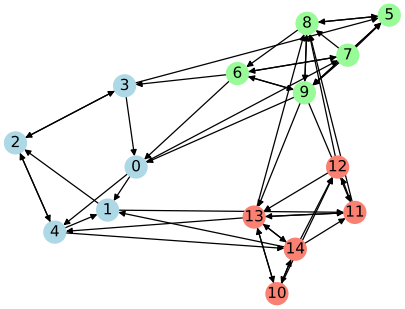
For reasons similar to soft-thresholding in (10) and (11), the cost function has to be differentiable with the control input to be designed. Thus, to design a control input within the first interval $\mathcal{I}_1$ in which firing must be promoted within the first module, we adopt an cost function such that

$$\sum_{k=l}^{l+T}\Bigg(\sum_{i\in\mathcal{V}_1} (1-\delta_i[k])(30 - c - (v_i[k+1] - v_i[k])) + \sum_{j\in\mathcal{V}_2} |v_j[k+1] - v_j[k]|\Bigg), \tag{12}$$

where

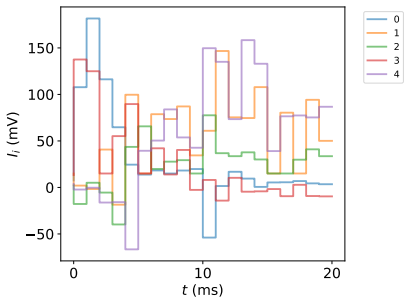
$$\delta_i[k] = \begin{cases} 1, & \text{if neuron } i \text{ fires at time } k, \\ 0, & \text{otherwise} \end{cases}$$

is a binary variable encoding the firing event of neurons. Minimization of the aforementioned cost function leads to a smaller first term, which then makes the amount of change in the membrane potential of the neurons in module $\mathcal{V}_1$ bigger, thereby stimulating neurons in the module $\mathcal{V}_1$ to fire. Conversely, we introduce the second term in (12) to suppress firing within the other module $\mathcal{V}_2$. For the aforementioned reasons, the cost function after the switching time T_s is set as



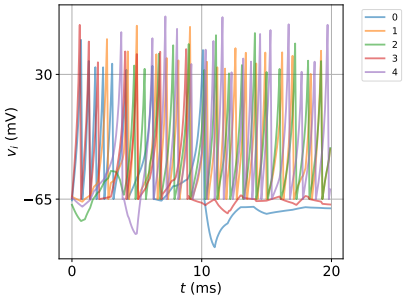
$$\sum_{k=l}^{l+T}\Bigg(\sum_{i\in\mathcal{V}_1} |v_i[k+1] - v_i[k]| + \sum_{j\in\mathcal{V}_2} (1-\delta_j[k])(30 - c - (v_j[k+1] - v_j[k]))\Bigg).$$

IV. Results and Discussions



In this section, we discuss the effectiveness of the proposed approach via numerical simulations. We considered neuronal networks consisting of "fast spiking" neurons described in [6]. Therefore, the model parameters in (8) and (9) were set to $a = 0.1$, $b = 0.2$, $c = -65$, and $d = 2$. Additionally, we set the amount of current flux incoming from neighboring neurons as $I_{\text{ex}} = 15\,\text{mV}$ and $I_{\text{in}} = -3\,\text{mV}$. For the neuronal network, we assumed that 80% of the neurons were of the excitatory type, while 20% were inhibitory neurons. Further, we assumed that the network consisted of three different modules (or clusters) such as $\mathcal{V}_1$, $\mathcal{V}_2$, and $\mathcal{V}_{\text{control}}$. As stated in Problem 1, we aimed to design the control input into the neurons in $\mathcal{V}_{\text{control}}$ to control the firing patterns in modules $\mathcal{V}_1$ and $\mathcal{V}_2$.

The (hyper-)parameters of the proposed method were chosen as follows. First, Adam was chosen as the optimizer, an algorithm used for updating the control input, based on existing literature [16]. Second, similar to [8], incremental learning was adopted during the process of control input learning. Third, for the Python implementation of TDU-MPC, we used libraries such as PyTorch [17] and NumPy [18]. Last, the time step for discretization was set to $\Delta t = 1\,\text{ms}$, while the prediction horizon within TDU-MPC was set as $T = 10$ step. Furthermore, for the soft-thresholding function (11), we chose parameter $\sigma = 0.38$.



As aforementioned, we first generated a network with $N = 15$ neurons and performed a control experiment via numerical simulations. To construct a network with modules, we used the stochastic block model [19] with Modules $\mathcal{V}_{\text{control}} = \{0, 1, 2, 3, 4\}$, $\mathcal{V}_1 = \{5, 6, 7, 8, 9\}$, and $\mathcal{V}_2 = \{10, 11, 12, 13, 14\}$. Out of the 15 neurons, neurons 6, 9, and 13 were inhibitory, while the others were excitatory. The edge probability within the module was set to $1/2$, while the one between modules was set to $1/8$. Utilizing these parameters,

TABLE I: Numbers of fires in each of the modules

(a) $N = 15$

Neuron No. \ time (ms)	$0 \leq$ time < 10	$10 \leq$ time ≤ 20
5-9	**8**	4
10-14	2	**16**

(b) $N = 30$

Neuron No. \ time (ms)	$0 \leq$ time < 10	$10 \leq$ time ≤ 20
10-19	**12**	2
20-29	6	**23**

we obtained the network shown in Fig. 2a. Within the resulting network, although the number of connections between the modules are fewer than the ones within the modules, the inter-module connections are still bidirectional, which makes the control problem nontrivial.

For initializing the membrane potentials v_i and membrane recovery variables u_i, we first set the potentials to c and the recovery variables to 0. Thereafter, a random current was applied to all neurons for $10\,\mathrm{ms}$. After initialization, we performed neuronal network control using the method described in Section III. The switching and simulation times were set to $T_s = 10\,\mathrm{ms}$ and $T_e = 20\,\mathrm{ms}$, respectively. Our objective was to design control inputs $I_{0,\mathrm{control}}, \ldots, I_{4,\mathrm{control}}$ such that the firing pattern of $\mathcal{V}_1$ was more active than that of $\mathcal{V}_2$ in the time interval $\mathcal{I}_1 = [0\,\mathrm{ms}, 10\,\mathrm{ms}]$, and that of $\mathcal{V}_2$ was more active than $\mathcal{V}_1$ in the time interval $\mathcal{I}_2 = [10\,\mathrm{ms}, 20\,\mathrm{ms}]$.

The results of the control experiment are presented in Fig. 2. In Fig. 2b, the control input signals to neurons in $\mathcal{V}_{\mathrm{control}}$ obtained from our method have been illustrated. From the membrane potentials of neurons in $\mathcal{V}_1$ and $\mathcal{V}_2$ shown in Figs. 2d and 2e, respectively, we confirmed that module $\mathcal{V}_1$ fired frequently from the initial time to $t = 10\,\mathrm{ms}$ as compared with $\mathcal{V}_2$. Additionally, module $\mathcal{V}_2$ fired frequently from $t = 10\,\mathrm{ms}$ to $t = 20\,\mathrm{ms}$ when compared with $\mathcal{V}_1$, as desired. We observed that the average computation time for a control input for the duration of $1\,\mathrm{ms}$ was $106\,\mathrm{s}$. Thus, improvements to the current implementation for a shorter computational time are of practical importance.

Further, the simulation results with $N = 30$ neurons were observed. The modules were set as $\mathcal{V}_{\mathrm{control}} = \{0, 1, 2, \ldots, 9\}$, $\mathcal{V}_1 = \{10, 11, 12, \ldots, 19\}$, and $\mathcal{V}_2 = \{20, 21, 22, \ldots, 29\}$. Out of the 30 neurons, neurons 3, 4, 6, 20, 26, and 27 were inhibitory, while the others were excitatory. The edge probability within the network was set to $1/2$, while the one between modules was set to $1/25$. With these parameters, we constructed a neuronal network with 30 neurons, as shown in Fig. 3a. Similar to our numerical experiment for the network with $N = 15$ nodes, we designed the control input $I_{i,\mathrm{control}}$ ($i \in \mathcal{V}_{\mathrm{control}}$) for the new network. The obtained time series of the control input has been shown in Fig. 3b. Further, the membrane potentials of $\mathcal{V}_1$ and $\mathcal{V}_2$ under the control input are shown in Figs. 3e and 3e, respectively. Modules $\mathcal{V}_1$ and $\mathcal{V}_2$ were confirmed to fire in the desired manner, and the average computational time for one step of the control input was $353\,\mathrm{s}$.

The results presented in Table I provide a summary of our numerical experiment for the two networks. Within the table, the number of fires in each of the modules for time intervals $\mathcal{I}_1$ and $\mathcal{I}_2$. The number of fires within the targeted module (the one required to be more active than the other) was confirmed to be no less than double the number of the one within the other module, thereby illustrating the effectiveness of the proposed method.

In both simulation results, initial time interval $\mathcal{I}_1$ corresponds to the period where module $\mathcal{V}_1$ should display higher firing activity. During this interval, the applied control input primarily activated the excitatory neurons in V_{control} having edges outgoing to $\mathcal{V}_1$. For instance, when considering $N = 15$ as an example, we can observe from Fig. 2b that neurons 0 and 3 were predominantly stimulated at the beginning of the time interval. As the switching time T_s approaches, the control input gradually diminished, effectively preventing firing within $\mathcal{V}_1$ in the subsequent time interval $\mathcal{I}_2$ when $\mathcal{V}_2$ was expected to exhibit high firing activity. Similarly, in the second time interval $\mathcal{I}_2$, we observed a comparable pattern to the aforementioned case. The excitatory neurons in V_{control} having edges outgoing to $\mathcal{V}_2$ were primarily stimulated. For instance, considering the case of $N = 15$ again, neurons 1 and 4 demonstrated increased activation during this time interval. These observed stimulation patterns align well with our intuitive understanding and expectations.

V. Conclusions

This study addressed the challenges associated with neuronal network control. We proposed a novel method for designing control inputs to manipulate the firing patterns of modules within a network. Based on TDU-MPC, our approach exploits deep unfolding techniques commonly used in wireless signal processing. The effectiveness of our proposed method was demonstrated via extensive numerical simulations.

Future research directions include evaluating the effectiveness of the proposed method via numerical experiments on other networks consisting of neurons other than the fast-spiking type. Additionally, robustness evaluation of the proposed method with respect to the modeling errors of the neurons can be of practical relevance, as the current research is conducted on the assumption that the dynamics of neurons are available and, therefore, errors in the model are assumed to be not significant. Another important research direction is the investigation of a method to design control inputs without the need to observe all membrane potentials.

Goodness of Fit to the Convolution Model of fMRI Data and Determination of the Regularization Parameter

***Abstract*—In the analysis of fMRI data, the time when the event of interest occurred in the experiment is usually used for analysis. However, in recent years, measurement of fMRI data which is not necessarily related to a certain simple event, such as measurement in resting state, is often performed. In this paper, we propose a method to analyze fMRI data without using time when events of interest occurred. In the proposed method, we fit a generation model of convolution form to fMRI data and obtain values of goodness of fit to the generation model. If the goodness of fit is sufficiently large for data from a voxel, the data can be considered to include a time course from neural activities. We suggest that this goodness of fit can be used to know whether the MR time series from a certain voxel contains a signal induced by neural activities or not. We propose a method to decide the value of the regularization parameter of the generation model using difference between data from voxels in gray matter and white matter. We compare the analysis result using the measure we proposed, the result by the fractional amplitude of low-frequency fluctuation (fALFF) and the result by generalized linear model using time course of events in the experiment. To evaluate analysis methods, we analyzed event related fMRI data. Both the index we proposed and the fALFF measure were similar to the result of analysis with generalized linear model, that is, usual analysis of variance. However, the measure we proposed showed higher correlation coefficient because of constant linear relation including range with large neural activities.**

I. Introduction

In conventional experiments of fMRI(functional Magnetic Resonance Imaging), data are obtained alternating a time period for the experimental condition and a time period for the control condition. In the analysis, data recorded with two conditions are compared. In recent years, fMRI data without a control condition are often recorded, such as data recorded when subjects are just resting or watching movies.

In this study, we propose a method to analyze fMRI data when the times of occurrences of events supposed to cause neural activities are not available. In the method, we assume a generation model of convolution form of fMRI data. We also assume the sparsity of occurrences of events which cause neural activities. With these assumptions, we fit the generation model to fMRI data and separate the data into a signal caused by neural activities and the sum of other components such as noises or artifacts. Further, the obtained signal is separated into a hemodynamic response function and a time series representing the time when each event occurred. Therefore, the time series of events is estimated from the fMRI data not knowing the design of the experiment. In this algorithm, a measure of goodness of fit to the convolutive generation model is defined and estimated from fMRI data measured in one voxel. For the voxel with a sufficiently large value of the measure, we assume that the fMRI data contain a fluctuation caused by neural activities. We suggest that this goodness of fit can be used to know whether some neural activity exists in a voxel or not.

The proposed measure of goodness of fit includes two terms, that is, a term of the residual between data and the model and a term of the sparsity of event occurrences. We need to decide the value of the regularization parameter which balances these two terms. We propose a method to decide the value using difference between data from voxels in gray matter and white matter.

The index called the fractional amplitude of low-frequency fluctuation (fALFF) proposed by Zou et al. (2008) [1] is an analysis method that does not use the time series of event occurences in the experiment. It uses the ratio of low frequency fluctuations as a measure of neural activities. Caballero-Gaudes et al. (2013) [2] proposed a method using the Dantzig selector to estimate a time series of events from fMRI data. After estimating the time series of events for each voxel, they proposed a method to define a time course of events common to all voxels and used it to obtain a map of neural activation.

For evaluation, we compare the analysis result by the proposed method and the result by the fractional amplitude of low-frequency fluctuation (fALFF). We analyzed a set of event related fMRI data. For the data, we knew when each event in the experiment occurred but we did not use the information for these two methods. We also analyzed the same data by the conventional analysis of variance using time courses of events in the experiment. The method is standard for fMRI and it assumes the generalized linear model. It uses t statistic showing the magnitude of fluctuations from neural activities caused by events of the experiment. We compare analysis results by these three methods.

II. Algorithm

A. The estimation of a_τ and $s(t)$

We use an algorithm similar to Olshausen and Field (1996) [3]. The algorithm is also based on an algorithm by Nakamura and Inouye (2009) [4]. We define $x(t)$ as an fMRI time series measured at a certain voxel. t represents the time or the index of fMRI scan. $s(t)$ is a time series and it takes 1 when an event such as presentation of a visual stimulus occurs, and takes 0 otherwise. We define a_τ as the fluctuation in fMRI data that an event caused. a_τ is a hemodynamic response function. With these variables, we suppose that the following equation represents the generation process of fMRI data

$$x(t) = \sum_{\tau=1}^{\tau_{\max}} a_\tau s(t-\tau+1) + \epsilon(t) \tag{1}$$

$\epsilon(t)$ represents additive noise and it follows a normal distribution and is uncorrelated in time. We assume that estimation of $s(t)$ can take any real number. We assume that the probability distribution of $s(t)$ is sparse as Olshausen and Field (1996) [3]. In summary, we assume the generation model of eq. (1) and the sparse distribution for the time series of stimuli. Then we estimate a_τ and $s(t)$ to minimize the next cost function.

$$L = \sum_t \left\{ x(t) - \sum_\tau a_\tau s(t-\tau+1) \right\}^2 + \lambda_s \sum_t \log(1+\beta s(t)^2) \tag{2}$$

This cost function can be interpreted as a log-likelihood function when $x(t)$ is given. Here we assume that the probability distribution of $s(t)$ is a truncated Cauchy distribution. This distribution is sparse.

$$p(s) = \begin{cases} \left(\frac{2}{\sqrt{\beta}} \tan^{-1}(\sqrt{\beta}\gamma)\right)^{-1} \frac{1}{1+\beta s^2}, & |s| \le \gamma \\ 0, & |s| > \gamma \end{cases} \tag{3}$$

We assume that $x(t) - \sum_\tau a_\tau s(t-\tau+1)$ follows a normal distribution. The probability distribution of $x(t)$ is

$$\begin{aligned} &p(x(1), x(2), \cdots, x(t), \cdots, x(T)) \\ &= \prod_{t=1}^{T} p(s(t)) \exp\left\{ \frac{(x(t) - \sum_\tau a_\tau s(t-\tau+1))^2}{\lambda_s} \right\} \end{aligned} \tag{4}$$

and eq. (2) is its log-likelihood function. The algorithm we use for estimation of parameters is the maximization of the posterior probability.

First, we determine the initial values of a_τ and $s(t)$. Then we iterate procedures for updating a_τ and $s(t)$ alternately. When we estimate both a_τ and $s(t)$ from data, we cannot estimate magnitudes of these variables. Therefore, we assume that $\sum_{\tau=1}^{\tau_{\max}} a_\tau^2 = 1$.

We update values of a_τ while values of $s(t)$ are fixed. Values of a_τ that minimizes the cost function L under the constraint $\sum_{\tau=1}^{\tau_{\max}} a_\tau^2 = 1$ can be obtained from the following equation. It is derived by Lagrange's undetermined multiplier method.

$$\begin{aligned} &\frac{\partial L}{\partial a_u} + 2\mu a_u = \\ &2\sum_t \left(\sum_\tau a_\tau s(t-\tau+1) - x(t) \right) s(t-u+1) + 2\mu a_u = 0 \\ &u = 1, 2, \cdots \tau_{\max} \end{aligned} \tag{5}$$

We can write the equation with vectors and matrices as follows. We define $\boldsymbol{a} = (a_1, a_2, \cdots, a_{\tau_{\max}})^T$. $\boldsymbol{c}_{sx}$ is a vector of length $\tau_{\max}$ and its k-th element is

$$\{\boldsymbol{c}_{sx}\}_k = \sum_t x(t) s(t-k+1) \tag{6}$$

The kl element of $\tau_{\max}$-by-$\tau_{\max}$ matrix C_{ss} is

$$\{C_{ss}\}_{kl} = \sum_t s(t-k+1) s(t-l+1). \tag{7}$$

Then, we can write eq. (5) as follows.

$$\frac{\partial L}{\partial \boldsymbol{a}} + 2\mu \boldsymbol{a} = 2C_{ss}\boldsymbol{a} - 2\boldsymbol{c}_{sx} + 2\mu\boldsymbol{a} = 0$$

By multiplying both sides by $\boldsymbol{a}^T$, we obtain the following equation.

$$\mu = -\boldsymbol{a}^T C_{ss} \boldsymbol{a} + \boldsymbol{a}^T \boldsymbol{c}_{sx} \tag{8}$$

To derive update rules by the Newton method, we calculate the second derivatives.

$$\frac{\partial}{\partial a_v}\left(\frac{\partial L}{\partial a_u} + 2\mu a_u \right) = 2\sum_t s(t-v+1) s(t-u+1) + 2\mu\delta_{uv} \tag{9}$$

Here, δ_{uv} is the Kronecker delta. From these equations, the next equation can be obtained.

$$\frac{\partial}{\partial \boldsymbol{a}}\left(\frac{\partial L}{\partial \boldsymbol{a}} + 2\mu\boldsymbol{a} \right) = 2C_{ss} + 2\mu I \tag{10}$$

I is the identity matrix.

Finally, the next update rules are obtained.

$$\begin{aligned} \boldsymbol{a} \leftarrow& \boldsymbol{a} - \left(\frac{\partial}{\partial \boldsymbol{a}} \left(\frac{\partial L}{\partial \boldsymbol{a}} + 2\mu\boldsymbol{a} \right) \right)^{-1} \left(\frac{\partial L}{\partial \boldsymbol{a}} + 2\mu\boldsymbol{a} \right) \\ &= (C_{ss} + (-\boldsymbol{a}^T C_{ss}\boldsymbol{a} + \boldsymbol{a}^T \boldsymbol{c}_{sx}) I)^{-1} \boldsymbol{c}_{sx} \end{aligned} \tag{11}$$

$$\boldsymbol{a} \leftarrow \frac{\boldsymbol{a}}{\|\boldsymbol{a}\|} \tag{12}$$

Next, we fix values of a_τ and update $s(t)$ simply by the gradient descent method with the cost function L.

$$s(t) \leftarrow s(t) - c\left(\frac{\partial L}{\partial s(t)} \right) \tag{13}$$

$$\begin{aligned} \frac{\partial L}{\partial s(t)} =& 2\sum_u \left(\sum_\tau a_\tau s(t+u+1-\tau) - x(t+u) \right) a_u \\ &+ \lambda_s \frac{2\beta s(t)}{1+\beta s(t)^2} \end{aligned} \tag{14}$$

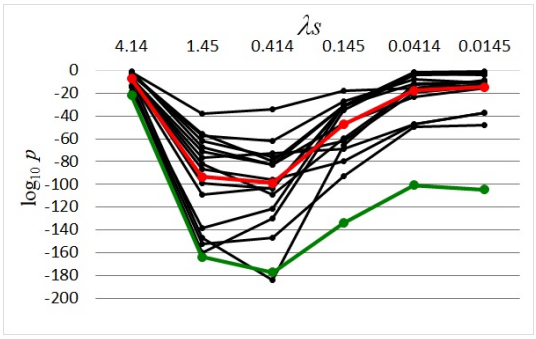

Fig. 1. p-values for the alternative hypothesis that values of L are smaller for voxels in the gray matter than the white matter. The common logarithms of p-values are shown. A black line is a result for each subject. The red line shows the mean of the common logarithm of p-values of all subjects. The green line shows the common logarithm of the mean of p-values of all subjects.

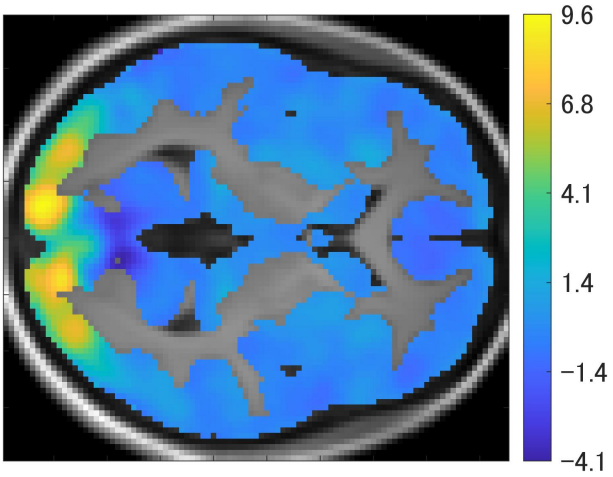

Fig. 2. Values of t-statistic using the usual analysis of variance approach. Mean values of 15 subjects. The slice of z=2.0mm.

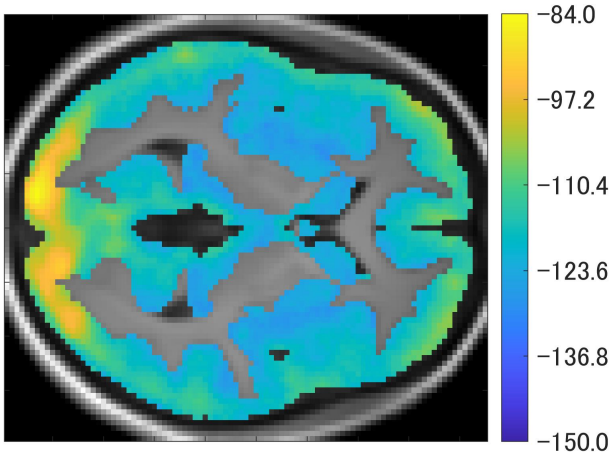

Fig. 3. Values of the measure of goodness of fit times -1, $-L$. Mean values of 15 subjects. The slice of z=2.0mm.

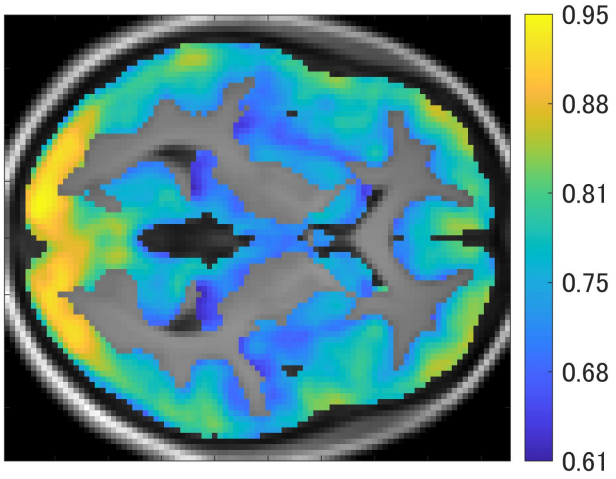

Fig. 4. Values of fALFF. Mean values of 15 subjects. The slice of z=2.0mm.

When an updated value of $s(t)$ is outside the range specified by its assumed probability distribution $p(s)$, we substitute it by the closest value in the range. That is, when $s(t)$ is updated by the gradient descent method, if $s(t) < -\gamma$, we substitute the update rule by $s(t) = -\gamma$. If $s(t) > \gamma$, then we apply $s(t) = \gamma$. We iterate the step updating a_τ with fixed $s(t)$ and the step updating $s(t)$ with fixed a_τ alternately, until the change of the cost function due to the update becomes sufficiently small. As described above, we estimate a_τ and $s(t)$ that minimize L.

The first term of L represents the residual between the data and the generation model and the second term represents sparseness of $s(t)$. λ_s is the parameter which balances these two terms. λ_s is a type of hyperparameter called regularization parameter. In the next section, we explain the method to determine the value of this parameter.

B. Estimation of the regularization parameter λ_s

We determine the value of λ_s as follows. First, we choose candidate values of λ_s. For each candidate value of λ_s, we estimate a_τ and $s(t)$ using the algorithm in the previous section that minimizes the cost function L. With estimated a_τ and $s(t)$, we examine the difference between values of L of voxels in white matter and voxels in gray matter. We calculate p-values of t-test corresponding to the alternative hypothesis that L is smaller in voxels in gray matter and select the value of λ_s with the smallest p-value.

With this λ_s, we determine β as follows. First, we assume that the mean and the variance of the data $x(t)$ are normalized to μ_x and one. If we assume the following approximation,

$$\sum_{t=1}^{T}\left\{\sum_{\tau=1}^{\tau_{\max}} a_\tau s(t-\tau+1)\right\}^2 \approx \left\{\sum_{\tau=1}^{\tau_{\max}} a_\tau^2\right\}\left\{\sum_{t=1}^{T} s(t)^2\right\} \tag{15}$$

then, from $\sum_{\tau=1}^{\tau_{\max}} a_\tau^2 = 1$, we obtain

$$\sum_{t=1}^{T}\left\{\sum_{\tau=1}^{\tau_{\max}} a_\tau s(t-\tau+1)\right\}^2 \approx \left\{\sum_{t=1}^{T} s(t)^2\right\} \tag{16}$$

Since $\epsilon(t)$ follows normal distribution with mean 0 and vari-

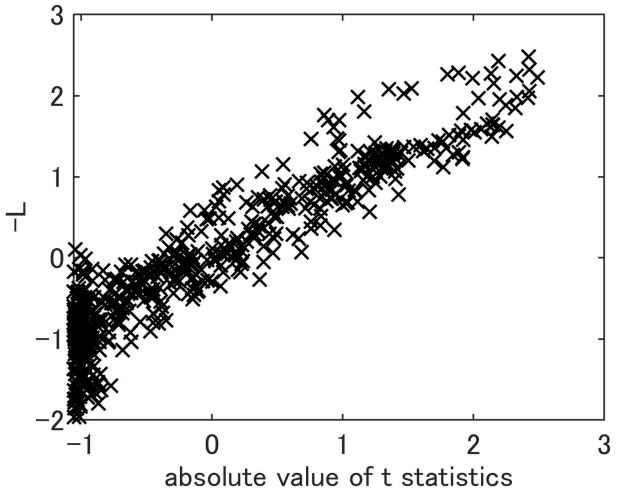

Fig. 5. The plot of $-L$ against the absolute value of t statistic. Both values are means of 15 subjects and normalized to mean 0 and variance 1. They are calculated from data recorded in gray matter on the z=2.0mm slice

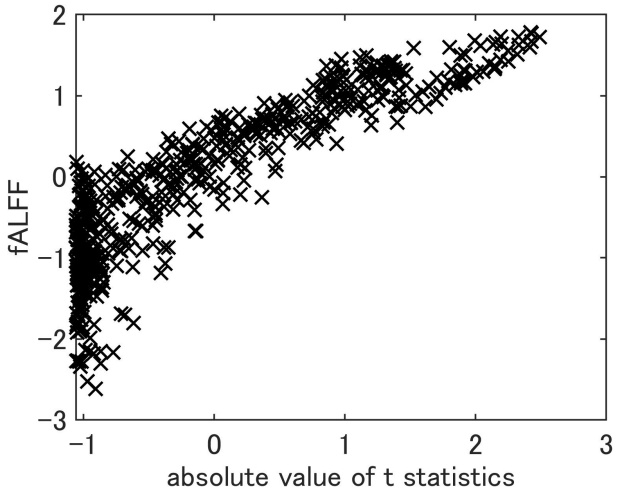

Fig. 6. The plot of fALFF against the absolute value of t statistic. Both values are means of 15 subjects and normalized to mean 0 and variance 1. They are calculated from data recorded in gray matter on the z=2.0mm slice

ance $\lambda_s/2$ and it is independent of $s(t)$,

$$\begin{aligned} \mathrm{E}\left[x(t)^2\right] &= \mathrm{E}\left[\left(\sum_{\tau=1}^{\tau_{\max}} a_\tau s(t-\tau+1)+\epsilon(t)\right)^2\right] \\ &= \mathrm{E}\left[\left(\sum_{\tau=1}^{\tau_{\max}} a_\tau s(t-\tau+1)\right)^2\right] + \mathrm{E}\left[\epsilon(t)^2\right] \\ &\approx \mathrm{E}\left[s(t)^2\right] + \frac{\lambda_s}{2} \end{aligned} \tag{17}$$

From the probability density function of s of eq. (3), the average of s^2 is

$$\mathrm{E}[s^2] = \frac{\gamma}{\sqrt{\beta}} \frac{1}{\tan^{-1}\left(\sqrt{\beta}\gamma\right)} - \frac{1}{\beta} \tag{18}$$

Since

$$\mathrm{E}\left[x(t)^2\right] = 1 + \mu_x^2 \tag{19}$$

we obtain the following equation.

$$\frac{\gamma}{\sqrt{\beta}} \frac{1}{\tan^{-1}\left(\sqrt{\beta}\gamma\right)} - \frac{1}{\beta} + \frac{\lambda_s}{2} = 1 + \mu_x^2 \tag{20}$$

By using eq. (20), if the values of λ_s and μ_x are given, we can calculate β.

III. Results

A. Data

We analyzed the data of Aminoff and Tarr (2015)[5]. They are available on the OpenfMRI[6] which is a website for data sharing. The data set includes data of 15 subjects. They are 12 females and 3 males and one subject is left-handed. They are 18 to 33 years old, with an average of 24. Aminoff and Tarr (2015)[5] studied information processing of the relationship between objects in the visual field. For this reason, they used an image in which cells are arranged in 4 by 4 and various objects are contained in some of these cells. In addition, images of landscapes and objects that are often seen in daily life and phase randomized images are used. In an image presentation block, four images are selected from these images, one image is presented twice and one presentation lasts 2[s]. One image presentation block lasts 16[s] and this block and a block that shows only a fixation point for 10 [s] are alternately arranged. One fMRI scan session includes 18 image presentation blocks. In our analysis, we focused on the difference between the time period in which images were presented and the time period in which only the fixation point was presented. The image presentations are treated as events of the experiment. We assume that a fluctuation is caused in fMRI data by the neural activity related to the events. We estimate the fluctuation and use it in the analysis of variance approach. We analyzed fMRI data measured in the slice of z= 2.0mm in MNI coordinates. The slice is in the primary visual cortex.

B. Determination of a value of λ_s

In the analysis of fMRI data, we used the following candidate values for λ_s. $\{4.14, 1.45, 0.414, 0.145, 0.0414, 0.0145\}$. With each value of λ_s, we calculate values of L for all voxels on the slice. Next, we calculate the p-value for a one-sided test of the alternative hypothesis that values of L are smaller for voxels in the gray matter than the white matter. Obtained p-values for each subject and the mean are shown in Fig.1.

For 9 subjects, the p-value was the smallest at $\lambda_s = 0.414$ and for 6 subjects, it was the smallest at $\lambda_s = 1.45$. Two kinds of means were both the smallest at $\lambda_s = 0.414$, but the difference from values with $\lambda_s = 1.45$ was small. We mainly present the results with $\lambda_s = 0.414$.

C. Measure of goodness of fit

We present results of the measure of goodness of fit L, fALFF, and the t statistic of the usual analysis of variance approach. Before we calculate a value of L, a time series $x(t)$

is normalized to have a mean of 1.25 and a variance of 1.00. Values of parameters are $\gamma = 10$ and $\tau_{\max} = 8$.

We calculated the means of 15 subjects of these variables and present them. In Fig. 2, we present the values of t statistic from the usual analysis of variance approach. In Fig. 3, we present the measure of goodness of fit to the convolutive generation model with sparse time series of event occurrences.The measure is multiplied by -1. In Fig. 4, we show values of fALFF. Both values of fALFF and values of $-L$ look similar to the values of t statistic. In some areas where t statistic is small, fALFF and $-L$ show large values.

We show the plot between these variables. The plot of $-L$ against the absolute value of the t statistic is shown in Fig. 5 and it shows high correlation. Both values are normalized to mean 0 and variance 1. The absolute value of the t statistic is used because a small negative value of the t statistic also means a relation with the experimental condition. The plot of fALFF against the absolute value of the t statistic is shown in Fig. 6 and it also shows high correlation. When the t statistic increases, fALFF stops increasing with it at some point and the slope between two values changes. The measure of goodness of fit keeps the same slope with large values of t statistic. The correlation coefficient between fALFF and the absolute value of the t statistic was 0.883 and the one between $-L$ and the absolute value of the t statistic was 0.929. With $\lambda_s = 1.45$, the latter was 0.954.

IV. Discussion

We proposed a method to obtain a measure of goodness of fit to the convolution model of fMRI. The measure showed high correlation with the conventional t statistic. The value of fALFF also showed high correlation with the t statistic, but the measure of goodness of fit showed higher correlation. The time course of the experiment of analyzed data is periodic. The method of fALFF may have worked well because of this periodicity. The measure L which we proposed does not utilize periodicity and may work also well for data with which we cannot assume periodicity of occurrences of events. The measure could be used to detect candidate areas of neural activation without making an assumption about what kind of event caused them.

For the proposed measure, we did not show how to decide the threshold of significance. The value of the regularization parameter λ_s determined by our method did not give the highest correlation among the candidate values. These problems should be considered in the future.

Acknowledgment

We thank Dr. Aminoff, Dr. Tarr and their colleagues for making their data public. The data were obtained from OpenfMRI website[6] and the accession number is ds000149.

***Abstract*— To evaluate the function of cohesin and its regulators, classifications of chromosomes based on the positional relationship between sister chromatids are used. Although the analysis has been done manually by researchers, we recently developed CNN-based classification models to automate the analysis. Our purpose in this study is to improve the accuracy of classification. For this purpose, we applied Vision Transformer (ViT) since ViT is expected to achieve better performance in the vision processing system than CNN. We show that the performance varies depending on the set of layers used in fine tuning. After proper fine tuning, the ViT-based model achieves higher classification accuracy than CNN.**

I. INTRODUCTION

In this paper, we propose a model for detecting sister chromatids cohesion defects based on Vision Transformer (ViT).

Sister chromatids are two identical copies of the same chromosome that are formed after DNA replication and are physically attached to each other until the onset of cell division. Subsequently, sister chromatids are equally distributed to daughter cells during somatic cell division. The physical attachment of sister chromatids until somatic cell division occurs is mediated by a ring-shaped protein complex called cohesin and proteins that regulate cohesin function [1]. Defects in proteins that regulate cohesin function result in the loss of sister chromatid cohesion and abnormalities in equal partitioning during mitosis [2]. It has been reported that such abnormalities cause various diseases, including cancer, developmental syndromes and infertility [3], [4]. For this reason, the mechanism of cohesin regulation has been studied since its discovery in 1997 [5]. To evaluate the involvement of proteins in the regulation of cohesin, a common method used in such studies is to classify the sister chromatid shapes after depletion of the protein of interest and to investigate the proportion of these shapes.

Traditional process for evaluating sister chromatid shape consists of three major steps: preparation of chromosome spreads, shape classification, and calculation of the ratio of each class. Currently, shape classification is done manually by researchers. The classification of sister chromatid shapes by manual inspection by researchers has two problems: it is time-consuming, and the classification results are dependent of subjective judgment of researchers. In our previous studies [6][14], we developed convolutional neural network (CNN) based models to enable automatic classification of sister chromatid shapes. Especially, two models based on DenseNet161 [7] and ShuffleNetV2 [8] pre-trained models achieved high accuracy classification. However, whether these trained models can be applied to different datasets (captured in different conditions) has not been examined.

In this study, we applied novel image classification models based on ViT. ViT, an application of the Transformer [11] used in the field of natural language processing, has attracted much attention because of its ability to achieve higher classification accuracy than CNN models [10]. We used four pre-trained models based on ViT and two pre-trained models based on CNN, and compared the performance of these models with varying number of layers used in fine tuning.

II. CONVENTIONAL MODELS

A. *Conventional Models [6][14]*

Our goal is to perform shape classification according to the degree of sister chromatid spreads. Although there are no standard classification criteria, we consider a model using CNN for classifying the sister chromatids into three classes in [6]. Namely, we classified them into classA, classB, classC : classA for images in which the two chromosomes are tightly connected, classB for images in which the arms are separated, and classC for images in which the two chromosomes are almost separated at the centromere. Illustrated images of each class are shown in Fig. 1.

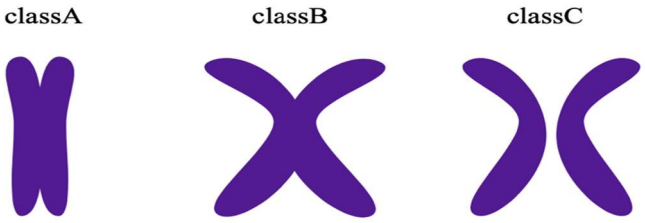

Fig. 1. Illustrated images of sister chromatids of each class

979-8-3503-0067-3/23/$31.00 ©2023 IEEE

In Ref. [6][14], image classification models are constructed by transfer learning and fine tuning using various CNN models which are pre-trained using images from ImageNet [9]. Because it is difficult to collect a large number of labeled images of sister chromatids for learning without pre-training. Based on the comparison of the accuracies, we proposed two image classification models based on DenseNet161 [7] or ShuffleNetV2 [8] and it is shown that they achieve high classification accuracy.

B. *Subject of This Study*

Although our previous models achieve the high accuracy rate, i.e., more than 90%, for the dataset described in the reference, in this study, we consider the models which can achieve higher classification validity. In previous studies, we only considered the models based on CNN. Here, the models based on the networks other than CNN, especially, the Vision Transformer, are considered.

III. PROPOSED MODEL

In this section, the proposed model is described. The proposed model is based on the Vision Transformer (ViT) instead of CNN.

A. *Vision Transformer (ViT) [10]*

For improving the accuracy of the previous method, we consider applying ViT as the base network instead of CNNs. ViT is derived from the Transformer [11] used in natural language processing (NLP) which employs the self-Attention mechanism instead of the convolutions used in CNNs.

Fig. 2 shows an architecture of ViT. The standard ViT consists of linear projection, Transformer encoder and Multi-Layer Perceptron (MLP) head. Besides, Transformer encoder consists of Multi Head Attention (MHA) blocks, which implement Attention mechanism, and MLP blocks. MHA extracts image features using the relevance of each image patch. The MLP consists of two layers with GELU (Gaussian Error Linear Unit). Transformer encoder in ViT receives each patch as an input, and the final layer of the Transformer encoder outputs the classification tokens used to make predictions.

B. *Multi Head Attention (MHA)*

MHA used in ViT is a mechanism to capture important parts of an image based on the similarity between each patch. MHA generates three vectors (query, key, and value) from each patch to the Transformer encoder of ViT. Then, we find a patch *Pr* with a large relevance based on the inner product between the query of a patch and the keys of all the patches. Next, we add the feature values of the patches with large relevance to the value of patch *Pr*. These operations are applied in parallel. As a result, ViT can recognize features of images globally. The number of operations performed in parallel is called Attention Heads.

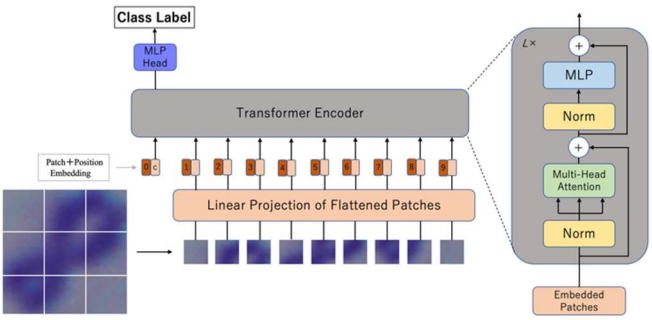

Fig. 2. Architecture of ViT [10]

C. *Model Variants*

In the following, we compare four pre-trained models of ViT available on the GitHub [12] or Torchvision [13]. Namely, we obtained ViT_Tiny and ViT_Small models from GitHub and the ViT_Base and ViT_Large models from Torchvision. These models of ViT are pre-trained using images from ImageNet [9]. Table I shows a comparison between those models. We use these models as the basic network of the proposed method.

Then, we perform fine tuning to each model with varying number of layers of Transformer encoder for which the fine tuning would apply. From the results, we investigate which layers are more effective for fine tuning.

Fig. 3 and Fig. 4 show the set of layers for which fine tuning would apply in each model. We note that ViT_Tiny, ViT_Small and ViT_Base have the same number of layers. These models differ in the number of attention heads and MLP size as Table I shows.

In the figures, LS stands for “layer set for fine tuning” and represents the set of layers used for fine tuning. For examples, ‘LS 1’ means that we use convolution layer through to fully connected layer of ViT_Tiny, ViT_Small and ViT_Base models for fine tuning. Similarly, ‘LS 2’ means that we use from transformer encoder 0 to fully connected layer.

Table I. The differences between the ViT models

Model	Input size	Patch size	Layers of Transformer encoder	MLP size	Attention Heads	Params
ViT_Tiny	224 × 224	16 × 16	12	768	3	5.5M
ViT_Small	224 × 224	16 × 16	12	1536	6	22M
ViT_Base	224 × 224	16 × 16	12	3072	12	86M
ViT_Large	224 × 224	16 × 16	24	4096	16	307M

D. *Fine Tuning*

As shown in Fig. 3 and Fig. 4, we divided the layers for fine tuning of ViT_Tiny, ViT_Small, and ViT_Base models into five patterns, and the layers for fine tuning of ViT_Large model into seven patterns.

During fine tuning, following parameters were used for all models: batch size is 32; number of epochs is 50; learning rate is 0.00003. Also, we used the Adam optimization algorithm, and cross-entropy as the loss function.

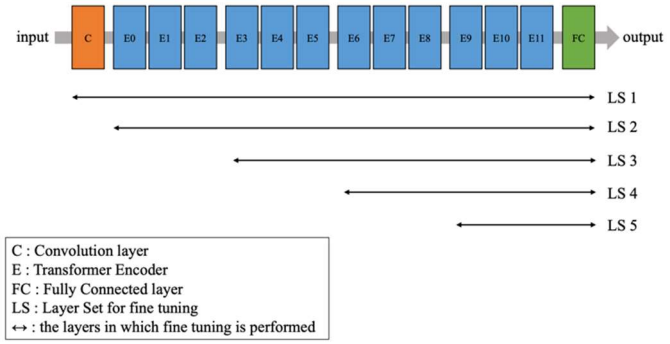

Fig. 3. The layer structure of ViT_Tiny, ViT_Small and ViT_Base models and the layers in which fine tuning is performed.

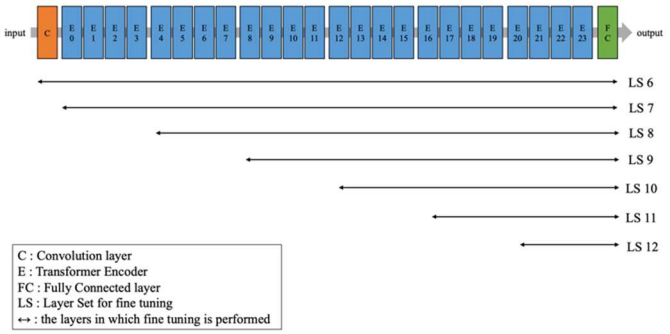

Fig. 4. The layer structure of ViT_Large model and the layers in which fine tuning is performed.

IV. EXPERIMENTS

Here, in order to verify the effectiveness of the proposed method, we show the results of experiments and the comparison with the previous method [6][14].

A. Datasets

Table II shows the composition of the datasets used in the experiments. These datasets are the same as used in [6]. We used the images of the sister chromatids taken by an author using a microscope. The images of these datasets were taken under same conditions at the same day. Note that, we applied the same pre-processing described in [6] to all images before the processing.

For the proposed method, fine tuning was performed using sister chromatids data consists of 667 images for training and 100 for validation in each class. To verify the effectiveness of the proposed method, we compared the accuracy of the proposed and the previous methods.

Table II. the composition of the datasets

	classA	classB	classC
Training Dataset	667 images (for training)	667 images (for training)	667 images (for training)
	100 images (for validation)	100 images (for validation)	100 images (for validation)
Dataset 1	100 images	100 images	100 images

B. Results

Here, we show the results of applying the four ViT models after fine tuning to Dataset 1 shown in Table II and compared their accuracy. Tables III and IV show the classification accuracy of Dataset 1 for each ViT model with different number of layers used for fine tuning.

Table III shows the results for the ViT_Tiny, ViT_Small and ViT_Base models. We can see from the table that, for ViT_Tiny and ViT_Base, the best results are obtained by the fine-tuning using LS 1. On the other hand, for ViT_Small, they are obtained when LS 2 is fine tuned. Table IV shows the results for the ViT_Large model and the best results are obtained when LS 6 is fine tuned.

Table III. The classification accuracy of the Dataset1 for ViT_Tiny, ViT_Small and ViT_Base models with different number of layers used for fine tuning.

	ViT_Tiny	ViT_Small	ViT_Base
LS 1	**0.9080**	0.9287	**0.9302**
LS 2	0.9053	**0.9300**	0.9244
LS 3	0.8998	0.9249	0.9227
LS 4	0.8553	0.9120	0.9118
LS 5	0.8340	0.8751	0.8802

Table IV. The classification accuracy of the Dataset 1 for ViT_Large model with different number of layers used for fine tuning.

	ViT_Large
LS 6	**0.9198**
LS 7	0.9164
LS 8	0.9176
LS 9	0.9116
LS 10	0.8993
LS 11	0.8938
LS 12	0.9007

Next, we compared the accuracy of the proposed and the conventional method [6][14]. Table V shows the best accuracy for each ViT model and the conventional method [6][14]. In Table V, we can see that the ViT_Base model has the highest accuracy.

Table V. Comparison of classification accuracy of each ViT model and the conventional method [6][14]

Proposed method	ViT_Tiny	0.9080
	ViT_Small	0.9300
	ViT_Base	**0.9302**
	ViT_Large	0.9198
Conventional method	DenseNet161	0.9002
	ShuffleNetV2	0.9198

C. Effectiveness of the proposed method

As described above, in our proposed method, we use the pre-trained ViT models, and then, apply the fine tuning to those models. Here, we compare the proposed method with a ViT without pre-training for verifying the effectiveness of the proposed method.

For that, we trained ViT_Base model from scratch using the training dataset shown in Table II and compared the classification accuracy for the same data. The results are shown in Table VI. We can see from the table that the accuracy of ViT model without pre-training is 0.8458 although the same network with pre-training achieves 0.9302 in the proposed method as shown in Tabel V. Hence, it is confirmed that the pre-training is effective in our situation where the number of images of the sister chromatids are not enough for training the models from scratch even if the ViT models are trained using the natural images from the dataset like ImageNet.

Note that we do not deny the possibility that the performance of a model trained from scratch may achieve better accuracy when a large number of images of sister chromatids are available. The comparison here shows the result in a situation where the number of images of sister chromatids available for training is limited.

Table VI. The classification accuracy of the Dataset 1 for ViT_Base model after fine tuning and non-pre-trained

After fine tuning	**0.9302**
Non-pre-trained	0.8458

D. Results with Different Dataset

To compare the performances of the proposed and the previous methods [6][14] for different evaluation data, we show the results of applying the methods to another dataset, which is referred as Dataset 2 in the following. As shown in Table VII, Dataset 2 consists of 104 images of class A, 345 of classB and 40 of class C. Note that Dataset 2 were taken using the same microscope but on a different day from the dataset shown in Table II were taken. In the following, we call the dataset in Table II as Dataset 1 to distinguish from Dataset 2. Fig. 5 shows examples from Dataset 1 (left) and from Dataset 2 (right).

Table VII. The composition of the dataset 2

	classA	classB	classC
Dataset 2	104 images	345 images	40 images

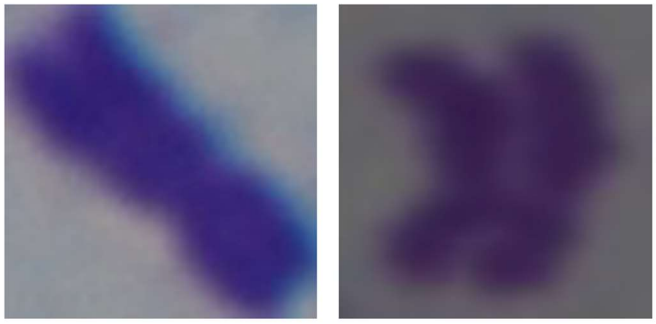

Fig. 5. Examples of the images from Dataset 1 (left) and Dataset 2 (right).

In Table VIII and IX, we show the results when Dataset 2 are used for the evaluation. Table VIII shows the results of the ViT_Tiny, ViT_Small and ViT_Base models. We can see from the table that, for ViT_Tiny and ViT_Small, the best results are obtained by the fine-tuning using LS 2. On the other hand, for ViT_Base, they are obtained when LS 4 is fine tuned. In Table IX, we show the results for the ViT_Large model and the best results are obtained when LS 6 is fine tuned.

Table VIII. The classification accuracy of the Dataset 2 for ViT_Tiny, ViT_Small and ViT_Base models with different number of layers used for fine tuning.

	ViT_Tiny	ViT_Small	ViT_Base
LS 1	0.6312	0.6964	0.6833
LS 2	**0.6511**	**0.7057**	0.6010
LS 3	0.6164	0.6830	0.6613
LS 4	0.4571	0.6669	**0.7016**
LS 5	0.3895	0.6083	0.6840

Table IX. The classification accuracy of the Dataset 2 for ViT_Large model with different number of layers used for fine tuning.

	ViT_Large
LS 6	**0.6660**
LS 7	0.6642
LS 8	0.6371
LS 9	0.5783
LS 10	0.5760
LS 11	0.6005
LS 12	0.5336

Finally, we compare the accuracy of the proposed and the conventional method for Dataset 1 and Dataset 2. Table X shows the best accuracy for each ViT model and the conventional method when we use Dataset 1 and Dataset 2. Note that, although the ViT_Small model has the highest accuracy for Dataset 2, we observed that the accuracies of both the proposed and the conventional methods decreased compared to them for Dataset 1. These results may suggest that the generalization of the network is not enough to achieve better classification regardless of the dataset from which evaluation data are taken. Hence, we need to increase the number of data used for learning to improve the robustness of the classification in the future.

Table X. Comparison of classification accuracy of each ViT model and the conventional method [6] for Dataset 1 and Dataset 2

		Dataset 1	Dataset 2
Proposed method	ViT_Tiny	0.9080	0.6511
	ViT_Small	0.9300	**0.7057**
	ViT_Base	**0.9302**	0.7016
	ViT_Large	0.9198	0.6660
Conventional method	DenseNet161	0.9002	0.6312
	ShuffleNetV2	0.9198	0.6191

V. Conclusions

In this paper, we proposed an image classification model for detecting the sister chromatids cohesion defects using the pre-trained ViT models. We applied fine-tuning to ViT with varying the set of layers to be tuned and compared in terms of the classification accuracy. By applying the model to the actual images of sister chromatids, we confirmed that the proposed model achieves the higher classification accuracy compared to our previous CNN based models. We also confirmed that the accuracy depends on the set of layers used for fine tuning.

***Abstract*—As online social networks provide people with a popular and convenient platform to express opinions, microblog sentiment analysis has become a hot research area. Currently, social relations between microblogs are extracted and integrated into content-based microblog sentiment analysis models. However, these methods take all links between microblogs into consideration, ignoring that some links are noisy and some neighbor microblogs are ambiguous semantically, resulting in the insufficiency of sentiment analysis. To deal with this problem, we propose a method that introduces sparse modeling of social contexts and tries to balance the sparsity and smoothness of social contexts to integrate social information prior knowledge into the content-based models in this paper. Specifically, a microblog graph is built based on sentiment consistency and emotional contagion, then we not only formalize the smoothness assumption of this graph but also introduce a graph-structured sparse regularization term to automatically select microblogs with high quality among all neighbors to facilitate sentiment analysis. Extensive experiments on two real-world public datasets show that our method achieves better performance than other baseline methods, indicating the effectiveness of sparse modeling of graph structure for microblog sentiment analysis.**

I. Introduction

With the rapid development of Web 2.0 and mobile communication devices, online social networks like microblogging services have become very popular for users to share information and opinions about various topics swiftly and conveniently. Twitter and Sina Weibo are among the most representative platforms. Almost every aspect of people's daily lives is published on these platforms, as a result, more and more user-generated content is flooded on the internet. These activities make mobile social networks become a huge resource repository, which draws the attention from governments, enterprises, and scholars. Microblog sentiment analysis has become a hot research topic in natural language processing and data mining. It arises in many applications such as recommendation systems, stock price prediction, and timely crisis management [1], [2], [3]. For example, due to the popularity, wide coverage, and rapid spread of microblogging platforms, microblog sentiment analysis can provide technical support for public opinion monitoring and early warning.

The problem of microblog sentiment analysis is to predict the sentiment (such as positive and negative) for microblog text. The existing works mainly take this problem as a classification task. Usually, they follow approaches of text classification: features are extracted from texts and represented as a vector by the bag of features, then machine learning methods are applied by implicitly assuming that microblog texts are independent [4], [5], [6], [7]. However, different from other texts such as news reports, microblog texts are very short and ambiguous. Slang, abbreviations, misspelled words, and other informal expressions are very common. It presents numerous difficulties in practice by exploiting textual data for microblog sentiment analysis. As a result, the accuracy of content-based methods drops sharply in real applications.

Microblogs lie in the environment of online social networks. These platforms provide rich social context information other than texts. For example, according to the theory of sentiment consistency [8], a user's sentiments have a higher probability to be the same in a short period about a specific topic. In addition, due to the theory of emotional contagion, a user's sentiment state can affect people around him or her [9], [10], [11], [12], which has been observed in online social networks [13], [14]. Inspired by these theories, some studies explore the utilization of social context information to facilitate microblog sentiment analysis [15], [16], [17], [18], [19], [20], [21]. They develop different methods to extract social context information between microblogs and use the extracted information to build a microblog graph and assume the graph is smooth, then they formalize the smoothness by graph Laplacian regularization or graph neural networks to integrate social knowledge information with microblog content. These methods utilize all the connections between microblogs in the graph by assuming that texts of all neighbors can facilitate sentiment analysis of the central microblog. However, this assumption does not always hold. Some neighbor microblogs are unfavorable to analyzing the sentiment of the central microblog if their text information is ambiguous. Besides, when extracting social

979-8-3503-0067-3/23/$31.00 ©2023 IEEE

context information by constructing the microblog graph, some noises may be introduced. It would be helpful to remove these noisy connections when analyzing sentiment. To solve these problems, we investigate how to remove noises and choose high-quality neighbors to facilitate microblog sentiment analysis automatically. specifically, we first build a microblog graph to extract social knowledge information, then we discuss how to integrate the graph with microblog texts and extract beneficial relationships from the graph in a sparse modeling method. In addition, we also take the smoothness of the built microblog graph into consideration by balancing it with the sparse term. The main contributions of our work are: 1) building a microblog graph based on the sentiment consistency and emotional contagion theory. 2) proposing a graph structured sparse regularization to automatically choose helpful microblogs from all neighbors and use related microblogs to perform feature selection. 3) balancing the graph structured sparse regularization term and the graph smoothness regularization term. 4) elaborating the effectiveness of the proposed method by conducting extensive experiments on two datasets.

II. Related Works

Microblog sentiment analysis has been a hot research topic, attracting enormous attention from researchers, companies, and governments. Existing methods mostly regard microblog texts as the only source and focus on extracting better representations for sentiment analysis by lexicons or machine learning methods. Some researchers utilized word lexicons to incorporate sentiment analysis. For example, Wu et al. built a new lexicon for Chinese microblog sentiment analysis by exploiting word emoticons relationships, word sentiment relationships, and existing sentiment lexicons [22]. A sentiment lexicon was built in [23] by selecting representative seeds and propagating sentiment labels among a graph of sentiment units built by social relations, topic, and so on. There are also some researchers who exploit machine learning methods for microblog sentiment analysis. [24] utilized probabilistic word sampling and word identification for zero masking or contextual replacement to augment sentiment datasets. Zhang et al. argued that the existing pre-trained methods considered features and fine-tuning methods separately, so they proposed a multi-task representation method [25]. However, these methods are content-centric, some researchers argue that their limitations come from focusing on content information only while ignoring language's social factors [26], [27].

Social contexts are explored in many social network analysis tasks such as recommendation systems [28], information retrieval [29], and fake news detection [30]. There are also few scholars studying the influence of social contexts on microblog sentiment analysis. [15] used the direct relationship between users, and integrated social relations with the least square method. [19] introduced community information for microblog sentiment analysis by multi-task learning. Although these methods integrated social contexts with microblog sentiment analysis, they ignore that social contexts may be noisy. There are also works that exploited graph neural networks to incorporate social contexts with text information [20], [21]. Although these works can assign different weights to different neighbors in the graph, they did not investigate how the sparse modeling of a graph can influence sentiment analysis and are not well explainable. [17] utilized user information and friend information to refine the sentiment labels of microblogs predicted by the logistic regression model or support vector machine. This work is the most similar to ours, as they also dealt with the noises in social contexts. Our work differs from this work in several fundamental aspects. [17] explored social contexts in the testing stage, while our work explores social contexts in a sparsity view in the training stage and investigates how sparse modeling influence the feature selection. In addition, our work not only exploits sparse modeling, we also take the smoothness of social contexts into consideration.

III. Problem Fromulation

A. Background & Notations

Matrixes are used uppercase bold letters such as $\mathbf{X}$ to represent, and vectors are represented by lowercase bold letters like $\mathbf{x}$. Lowercase letters like α denote scalar values. $\mathbf{X}_{i*}$ and $\mathbf{X}_{*j}$ denote the i-th row and the j-th column of the matrix $\mathbf{X}$ respectively. $\mathbf{A}_{ij}$ represents the element located at the i-th row and j-th column. $\mathrm{Tr}(.)$ computes the trace of a matrix. The norm $||.||_1$ is the sum of vector magnitudes in a space, the norm $||.||_2$ means to make the value of every dimension to be small, which can also be explained by minimizing the distance between the origin and the coordinate in the vector space.

Given that $\mathbf{x}^i \in R^m$ represents the i-th microblog feature vector, m is the number of features, then the sentiment prediction problem can be defined as a loss function $\mathcal{L}(\mathbf{x}^i, \mathbf{w}, y^i)$ which quantifies the loss between the prediction $h_{\mathbf{w}}(\mathbf{x}^i)$ of a classifier and the true class label $y^i \in \mathcal{Y}$ associated with the sample $\mathbf{x}^i \in \mathcal{X}$. $\mathcal{X}$ represents the microblog texts set, $\mathcal{Y}$ represents the sentiment label set. $\mathbf{w}$ is the parameters of the classifier, which represents the feature weight vector. Given the microblog training set $\{(\mathbf{x}^i, y^i)\}_{i=1,\cdots,n}$, we can get a classifier $\mathbf{w}$ by optimize the set of feature weights using:

$$\mathbf{w}^* = \mathrm{argmin}_{\mathbf{w}} \quad \sum_{i=1}^{n} \mathcal{L}(\mathbf{x}^i, \mathbf{w}, y^i), \tag{1}$$

where n represents the number of microblogs in the traning set. $\mathcal{L}(\mathbf{x}^i, \mathbf{w}, y^i)$ can be logistic regression, least squares or other losses. In this paper, we use the squared loss as an example: $\mathcal{L}(\mathcal{X}, \mathbf{w}, \mathcal{Y}) = \frac{1}{2}\sum_{i=1}^{n}(\mathbf{x}^i\mathbf{w} - y^i)^2$. It also can be rewritten in the form of matrix calculation: $\mathcal{L}(\mathcal{X}, \mathbf{w}, \mathcal{Y}) = \frac{1}{2}||\mathbf{X}\mathbf{w} - \mathbf{y}||_2^2$, where $X \in R^{n\times m}$ is the feature matrix of the training set, m represents the number of features, $\mathbf{x}^i = \mathbf{X}_{i*}$ represents the feature vector of the i-th microblog. $\mathbf{y} \in R^{n\times 1}$ represents the label vector. We focus on binary sentiment analysis, so for any microblog, its sentiment label satisfies: $y^i \in \{-1, +1\}$. For a positive microblog, $y^i = +1$.

B. Regularization

Regularization is proven to be of paramount importance in language modeling and text classification [31]. It can not only avoid overfitting in the training stage, but also take prior knowledge into consideration [32]. Unlike texts in traditional media, microblogs are extremely short and ambiguous, containing lots of abbreviations, slang, and personalized expressions. This characteristic often leads to a high-dimension feature vector space when representing microblog texts by the unigram model. In addition, it makes the feature vector very sparse. So the sparse regularization L_1 norm is utilized to reconstruct a sparse space from the high-dimension one:

$$\mathbf{w}^* = \text{argmin}_{\mathbf{w}} \quad \mathcal{L}(\mathcal{X}, \mathbf{w}, \mathcal{Y}) + \beta||\mathbf{w}||_1, \tag{2}$$

where β is a hyper-parameter. The L_1 norm assumes a multivariate Laplacian prior on the feature weight vector $\mathbf{w}$. Minimizing the L_1 norm will set some feature weights to 0, which means automatically selecting features. The L_1 norm regularization is used as an additional constraint to the classification problem, by relaxing into a penalty term controlled via a hyper-parameter β.

Emotional contagion

IV. Microblog Sentiment Analysis Via Graph Structured Sparse Regularization

A. Modeling microblog content informaiton

In a sentiment prediction problem, pre-processing is the first step and its quality can influence the analysis results. To better represent microblog texts, references [33] and [34] conduct experiments to compare the effects of different preprocessing methods and features. Following these studies, we use the unigram model with term presence and do not remove punctuation and stop words as they carry sentiment information. In addition, online social networks provide some mechanisms for users to better express their emotions and opinions, such as hashtags, @-mentions, and emoticons. In microblogs, hashtags are marked with the symbol # and used to indicate the topic of microblogs. For example, the microblog "I love #ipad" infers this is about "ipad". As topic information is very important for sentiment analysis, we preserve hashtags in microblog texts. Different from formal texts in which body language and verbal tone do not translate, emoticons are a popular way for people to convey their nuanced meaning in online social networks. So emoticons are extracted as features by regular expressions. @-mentions and URLs are also preserved in this paper as they may contain some sentiment clues.

B. Extracting and Modeling Social Knowledge Information

In addition to text information, online social networks also contain the information of the user (such as following and followee information) who posted the text. The environmental information may provide sentiment clues. In this section, we construct a microblog graph to reveal their sentiment clues by using the social knowledge information from sociological theories. The microblog graph is represented as $\mathcal{G} = (\mathcal{V}, \mathcal{E})$, where the node set $\mathcal{V}$ is composed of microblogs, and the edge set $\mathcal{E}$ contains connections between microblogs. We use matrix $\mathbf{A}$ to represent its adjacency matrix. Firstly, the sentiment of a specific user tends to be consistent in a short period, which is called the sentiment consistency theory [8]. This phenomenon means that microblogs posted by the same user within a short time interval are more likely to have the same sentiment. To extract this prior social knowledge information, we construct a microblog graph $\mathcal{G}_1$ whose adjacency matrix $\mathbf{A}_{sc}$ can be computed by $\mathbf{A}_{sc} = \mathbf{U}^T \times \mathbf{U}$. $\mathbf{U} \in R^{d \times n}$ denote the user-microblog matrix, n is the number of microblogs, d is the number of users. $\mathbf{U}_{ij} = 1$ if the i-th user posted the j-th microblog. Otherwise, $\mathbf{U}_{ij} = 0$. In this case, if microblog i and microblog j are posted by the same user, then $\mathbf{A}_{sc_{ij}} = 1$, otherwise, $\mathbf{A}_{sc_{ij}} = 0$. Secondly, sentiment diffusion has been reported in online social networks based on emotional contagion and has close relationships with microblog sentiment polarities in social sciences [9], [35]. The analysis indicates that emotional contagion may be helpful for microblog sentiment analysis. Emotional contagion reveals that if two microblogs are published by friends, their sentiment polarities are more likely to be similar. Based on this theory, we use the friend information $\mathbf{F} \in R^{d \times d}$ provided by microblogging services to build the microblog graph $\mathcal{G}_2$. Its adjacency matrix can be computed by $\mathbf{A}_{ec} = \mathbf{U}^T \times \mathbf{F} \times \mathbf{U}$. $\mathbf{F}_{ij} = 1$ if and only if the i-th user is a friend of the j-th user, otherwise, $\mathbf{F}_{ij} = 0$. Therefore, $\mathbf{A}_{ec_{ij}} = 1$ when the i-th microblog and the j-th microblog are posted by connected users, otherwise, $\mathbf{A}_{ec_{ij}} = 0$. After all these steps, we get a new graph $\mathcal{G}$ whose adjacency matrix is $\mathbf{A} = \mathbf{A}_{sc} + \mathbf{A}_{ec}$.

Based on the discussion above, the built micorblog graoh is smooth. Microblog texts connected by edges in a graph $\mathcal{G}$ are published by the same user or friends, which means that they usually convey similar sentiment. Therefore, we try to construct a connection to make the sentiment of connected microblogs as close as possible. Similar sentiment scores are assigned to connected microblogs in our method. **Graph Laplacian regularization** is used to model the smoothness:

$$\begin{aligned} &\text{argmin}_{\mathbf{w}} \quad \frac{1}{2}\sum_{i=1}^{n}\sum_{j=1}^{n}\mathbf{A}_{ij}||\hat{y^i} - \hat{y^j}||_2^2 \\ =&\text{argmin}_{\mathbf{w}} \quad \frac{1}{2}\sum_{i=1}^{n}\sum_{j=1}^{n}\mathbf{A}_{ij}||\mathbf{x}^i\mathbf{w} - \mathbf{x}^j\mathbf{w}||_2^2 \\ =&\text{argmin}_{\mathbf{w}} \quad \text{Tr}((\mathbf{X}\mathbf{w})^T\mathbf{L}\mathbf{X}\mathbf{w}), \end{aligned} \tag{3}$$

where $\hat{y^i}$ represents the predicted sentiment label, $\mathbf{L}$ denotes the Laplacian matrix of graph $\mathcal{G}$ and can be computed by $\mathbf{L} = \mathbf{D} - \mathbf{A}$. $\mathbf{D}$ represents the diagonal matrix whose entries represent the number of neighbors of the i-th microblog.

In addition to graph Laplacian regularization, we introduce a novel method (**graph structured sparse regularization**, also called **graphical lasso regularization**) to model the social knowledge information prior in this paper. In graph Laplacian regularization, the influence of all neighbors of a microblog is taken into consideration by assuming that the texts of all neighbors can help sentiment analysis. Similar to the L_2 norm regularization, graph Laplacian regularization results in

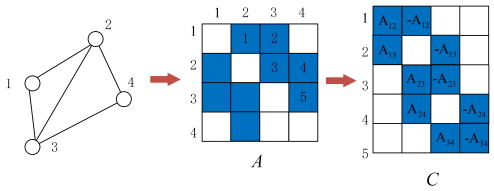

Fig. 1. An example of construction of C

reducing values. However, when building the microblog graph, some noises are introduced and not all neighbors are helpful for microblog sentiment. Some microblogs are predicted with high confidence coefficient because they have words with clear sentiment polarities, while many other microblogs without clear sentiment words are predicted as incorrect labels with a high probability. Under this scenario, it would be helpful to choose the microblog texts containing sentiment words among all the neighbors. To solve this problem, A graph structured sparse regularization term is proposed. It can be formulated as:

$$\begin{aligned} & \text{argmin}_{\mathbf{w}} \quad \sum_{i=1}^{n}\sum_{j=1}^{n}\mathbf{A}_{ij}||\hat{y}^i - \hat{y}^j||_1 \\ = \ & \text{argmin}_{\mathbf{w}} \quad \sum_{i=1}^{n}\sum_{j=1}^{n}\mathbf{A}_{ij}||\mathbf{x}^i\mathbf{w} - \mathbf{x}^j\mathbf{w}||_1 \\ = \ & \text{argmin}_{\mathbf{w}} \quad ||\mathbf{C}\mathbf{X}\mathbf{w}||_1, \end{aligned} \tag{4}$$

where $\mathbf{C} \in R^{|\mathcal{E}|\times n}$, $|\mathcal{E}|$ represents the number of edges in graph $\mathcal{G}$. Fig. 1 shows an example of the construction this matrix, blue boxes denote the nonzero elements. First, due to the fact that the adjacency matrix $\mathbf{A}$ is symmetric, we number the nonzero entries of the matrix $\mathbf{A}$ above the diagonal in ascending order from top to bottom and left to right. Second, if $\mathbf{A}_{ij}$ is nonzero and located in the n-th position, then $\mathbf{C}_{ni} = \mathbf{A}_{ij}$ and $\mathbf{C}_{nj} = -\mathbf{A}_{ij}$. The rest of elements are set to zeros in this row.

To integrate content-based methods and social knowledge information for microblog sentiment analysis, a unified framework **GRALA** is proposed:

$$\begin{aligned} \text{argmin}_{\mathbf{w}} \quad \mathcal{F} =& \mathcal{L}(\mathcal{X}, \mathbf{w}, \mathcal{Y}) + \lambda||\mathbf{C}\mathbf{X}\mathbf{w}||_1 \\ &+ \frac{\alpha}{2}\text{Tr}((\mathbf{X}\mathbf{w})^T\mathbf{L}\mathbf{X}\mathbf{w}) + \beta||\mathbf{w}||_1, \end{aligned} \tag{5}$$

where $\mathcal{L}(\mathcal{X}, \mathbf{w}, \mathcal{Y})$ is the loss function of content-based microblog sentiment methods, $||\mathbf{C}\mathbf{X}\mathbf{w}||_1$ and $\text{Tr}((\mathbf{X}\mathbf{w})^T\mathbf{L}\mathbf{X}\mathbf{w})$ are the regularization terms to explore social information prior knowledge from the sparsity and smoothness view respectively. $||\mathbf{C}\mathbf{X}\mathbf{w}||_1$ is the graphical lasso regularization term which automatically chooses helpful neighbour microblogs, while $\text{Tr}((\mathbf{X}\mathbf{w})^T\mathbf{L}\mathbf{X}\mathbf{w})$ tries to make the sentiment of connected microblogs as close as possible. α, β, and λ are the hyper-parameters to balance the weights of different regularization terms.

C. Optimization Algorithm

The optimization problem in (5) is convex. However, as $||\mathbf{C}\mathbf{X}\mathbf{w}||_1$ and $||\mathbf{w}||_1$is not smooth, it is not easy to solve it directly. The ADMM algorithm is utilized to solve it. Equation (5) can be reformulated as:

$$\text{argmin}_{\mathbf{w}} \quad \mathcal{F} = \mathcal{L}(\mathcal{X}, \mathbf{w}, \mathcal{Y}) + ||\mathbf{H}\mathbf{w}||_1 + \tfrac{\alpha}{2}\text{Tr}((\mathbf{X}\mathbf{w})^T\mathbf{L}\mathbf{X}\mathbf{w}), \tag{6}$$

where $\mathbf{H} \in R^{(1+|\mathcal{E}|)\times m}$, $\mathbf{H} = \begin{bmatrix} \beta \\ \lambda\mathbf{C}\mathbf{X} \end{bmatrix}$. Let $\mathbf{H}\mathbf{w} = \mathbf{v}$, (6) can be rewritten as:

$$\begin{aligned} \text{argmin}_{w} \quad & \mathcal{L} = \mathcal{L}(\mathcal{X}, \mathbf{w}, \mathcal{Y}) + ||\mathbf{v}||_1 + \frac{\alpha}{2}\text{Tr}((\mathbf{X}\mathbf{w})^T\mathbf{L}\mathbf{X}\mathbf{w}) \\ \text{s.t.} \quad & \mathbf{v} = \mathbf{H}\mathbf{w}. \end{aligned} \tag{7}$$

An augmented Lagrangian problem is used to solve (7):

$$\begin{aligned} \text{argmin}_{w} \quad \mathcal{F} \ = \ & \mathcal{L}(\mathcal{X}, \mathbf{w}, \mathcal{Y}) + ||\mathbf{v}||_1 + \frac{\alpha}{2}\text{Tr}((\mathbf{X}\mathbf{w})^T\mathbf{L}\mathbf{X}\mathbf{w}) \\ & + \mu^T(\mathbf{H}\mathbf{w} - \mathbf{v}) + \frac{1}{\rho}||\mathbf{H}\mathbf{w} - \mathbf{v}||_2^2. \end{aligned} \tag{8}$$

Let $\mathbf{u} = \frac{\mu}{\rho}$ as the scaled dual variable, ρ is a positive penalty coefficient, (8) can be reformulated as:

$$\begin{aligned} \text{argmin}_{w} \quad \mathcal{F} \ = \ & \mathcal{L}(\mathcal{X}, \mathbf{w}, \mathcal{Y}) + ||\mathbf{v}||_1 + \frac{\alpha}{2}\text{Tr}((\mathbf{X}\mathbf{w})^T\mathbf{L}\mathbf{X}\mathbf{w}) \\ & + \frac{\rho}{2}||\mathbf{H}\mathbf{w} - \mathbf{v} + \mathbf{u}||_2^2 - \frac{\rho}{2}||\mathbf{u}||_2^2. \end{aligned} \tag{9}$$

Essentially, the problem becomes the iterative update of $\mathbf{w}$, $\mathbf{v}$ and $\mathbf{u}$:

$$\begin{aligned} \mathbf{w}_{t+1} \ = \ & \text{argmin}_{\mathbf{w}} \quad \mathcal{L}(\mathcal{X}, \mathbf{w}, \mathcal{Y}) + \frac{\rho}{2}||\mathbf{H}\mathbf{w} - \mathbf{v}_t + \mathbf{u}_t||_2^2 \\ & + \frac{\alpha}{2}\text{Tr}((\mathbf{X}\mathbf{w})^T\mathbf{L}\mathbf{X}\mathbf{w}), \end{aligned} \tag{10}$$

$$\begin{aligned} \mathbf{v}_{t+1} \ &= \ \text{argmin}_{\mathbf{v}} \quad ||\mathbf{v}||_1 + \frac{\rho}{2}||\mathbf{H}\mathbf{w}_{t+1} - \mathbf{v} + \mathbf{u}_t||_2^2 \\ &= \ S_{1/\rho}(\mathbf{H}\mathbf{w}_{t+1} + \mathbf{u}_t), \end{aligned} \tag{11}$$

where S is soft-thresholding operator.

$$\mathbf{u}_{t+1} \ = \ \mathbf{u}_t + \rho * (\mathbf{H}\mathbf{w}_{t+1} - \mathbf{v}_{t+1}). \tag{12}$$

To minimize (10), we set the gradient with $\mathbf{w}$ to zero, as $\mathcal{L}(\mathcal{X}, \mathbf{w}, \mathcal{Y})$ in this paper is the least squares, then we can update $\mathbf{w}$ by:

$$\mathbf{w}_{t+1} = (\mathbf{X}^T\mathbf{X} + \rho\mathbf{H}^T\mathbf{H} + \alpha\mathbf{X}^T\mathbf{L}\mathbf{X})^{-1}(\mathbf{X}^T\mathbf{y} + \rho\mathbf{H}^T(\mathbf{v}_t - \mathbf{u}_t)). \tag{13}$$

The detail of our proposed optimization method is shown in Algorithm 1.

V. EXPERIMENTS

Two real public datasets (OMD [36] and HCR [37]) are used to conduct experiments in this paper. Friend information is from the complete follower graph built by [38]. We randomly select 80% microblogs as the training set, the left 20% microblogs are used as the testing set. Results of different methods are evaluated by classification accuracy and the weighted average F_1-score. The hyper-parameters are chosen by cross validation.

Algorithm 1: The proposed optimization algorithm for microblog sentiment analysis

Input: $\mathbf{X}$, $\mathbf{y}$, $\mathbf{A}$, α, β, λ, ρ.
Output: $\mathbf{w}$

Initialize Initialize $\mathbf{w}_0 = \mathbf{w}_1 = \mathbf{0}$, $\mathbf{u}_0 = 0$, $\mathbf{v}_0 = 0$, $t = 0$;
while *not convergent* **do**
  $t = t + 1$;
  compute $\mathbf{H}$;
  compute $\mathbf{L}$;
  update $\mathbf{w}_t$ using (13);
  $\mathbf{v}_t = S_{1/\rho}(\mathbf{H}\mathbf{w}_t + \mathbf{u}_{t-1})$;
  $\mathbf{u}_t = \mathbf{u}_{t-1} + \rho * (\mathbf{H}\mathbf{w}_t - \mathbf{v}_t)$;
end
$\mathbf{w} = \mathbf{w}_t$.

TABLE I
THE EFFECTIVENESS OF DIFFERENT PARTS

Method	F1(%)	Accu(%)
LS baseline	73.468	75.000
LS+L1	76.401	76.695
LS+L1+graph laplacian	77.413	78.390
LS+L1+graphical lasso	78.833	79.237
GRALA(LS+L1+graphical lasso+ graph laplacian)	**79.067**	**79.661**

A. The effectiveness of different regularization

The effectiveness of different parts in the loss function is evaluated. The OMD dataset is used as an example. The results are shown in Table I. "LS+L1" represents the content-based method with the L_1 norm regularization. "LS+L1+graph laplacian" represents the content-based method with graph Laplacian and the L_1 norm regularization. "LS+L1+graphical lasso" represents the content-based method with the graphical lasso and the L_1 norm regularization. "GRALA" represents our proposed method. From this figure, we can see that compared with the baseline content-based method, adding L_1 norm regularization can improve the sentiment analysis results. This indicates that not all features are useful for sentiment classification. Integrating social knowledge information hasa positive influence on microblog sentiment analysis as both gralap and gralas outperform Lasso. The method GRALA achievesthe best performance because it combines theL_1 normregularization, graph Laplacian regularization, and graphicallasso regularization. GRALA can automatically choosehelpfulmicroblogs among all neighbors and make the sentiment ofconnected microblogs as close as possible at the same time.

B. Performance Comparisions

Our proposed method GRALA is compared with other state-of-the-art sentiment analysis models. These methods include the least squares (LS), logistic regression (LR), support vector machine (SVM), Naive Bayes classifier (NB), Convolutional Neural Network (CNN) [39], Long short-term memory neural network (LSTM) [40], SANT [15], SASS [18], GCN [20]. All microblogs in the training set are used to train all the classifiers. Results are shown in Table II. The LS, LR, SVM, NB, CNN, and LSTM are content-based methods. SANT, SASS and GCN are methods integrated with social knowledge information. From the experimental results, we can see that SANT, SASS, GCN and GRALA achieve better performance than other methods, which suggests that leveraging social network knowledge can improve microblog sentiment analysis results. Among all methods, our method performs best on both datasets, which indicates the effectiveness of graph structured sparse regularization.

VI. CONCLUSION

In this paper, we formulate microblog sentiment analysis by integrating social knowledge information and content information. More importantly, we investigate how sparse modeling of social contexts can influence microblog sentiment analysis. Particularly, we extract latent sentiment clues between microblogs based on the sentiment consistency and emotional contagion theory and assume that the sentiment of connected microblogs is similar. Then we propose a framework to balance the sparsity and smoothness of social contexts. Graph Laplacian regularization is utilized to represent the smoothness of the built graph, and graph structured sparse regularization is presented to model the sparsity of social information. As a result, microblogs with clear sentiment words are selected among neighbors automatically. The results of experiments conducted on two real-world public datasets show that our method performs better than other baseline methods and indicate the effectiveness of graph structured sparse regularization on microblog sentiment analysis. This work can suggest some interesting directions for future work. For example, it would be promising to integrate sparse modeling into graph neural networks to overcome the over-smoothing problem.

Adopting Neural Translation Model in Data Generation for Inverse Text Normalization

Yufei Jiang, Thi-Nga Ho, and Eng-Siong Chng
Nanyang Technological University, Singapore
E-mail: jian0133@e.ntu.edu.sg

***Abstract*—This research proposes a novel data generation pipeline for the Inverse Text Normalization task with a focus on improving the data alignment technique. The pipeline adopts Automatic Speech Recognition (ASR) and Neural Word Alignment techniques to facilitate the needs. The pipeline is a three-stage process from data crawling and spoken transcript generation to data alignment. Firstly, audio recordings and their corresponding written-form transcripts were collected in a semi-automatic manner. Subsequently, the audio recordings are sent to an ASR system to obtain spoken transcripts. Lastly, a cutting-edge word alignment technique is utilized to pair words between written and spoken transcripts to produce a word-level alignment ITN dataset. The proposed data alignment technique achieves at least 3.3% improvement in decimal word transformation compared to the representative baselines.**

I. Introduction

The objective of the research is to develop high-quality datasets for ITN research. A typical ITN dataset comprises two distinct sequences of sentences or words, i.e. the spoken and the corresponding written sequences. The spoken form is a verbatim representation of the audio in text, while the written form preserves the audio information but is organized in written format for better readability. For instance, a spoken transcript can be "nineteen eighty five", while its written form will be "1985". A few examples of spoken-written transcripts are illustrated in Table I.

TABLE I
Examples of spoken from written form pairs

Spoken Form	Written Form
Doctor is in room two zero three	Doctor is in room 203
It's twelve thrity now	It's 12:30 now
Please give me five apple	Please give me 5 apple
The car costs me three thousand dollors	The car costs me 3000$
He paid one hundred percent effort	He paid 100% effort
In twenty twenty one	In 2021

Despite advancements in recent ITN research, the scarcity of ITN training corpora remains an issue. The Google Text Normalization Dataset is the only sizeable public dataset for English, Russian, and Polish[1]. The dataset is structured at word-level with classification labels assigned to each word pair. Figure 1 shows a screenshot of labeled text data from Google Text Normalization Corpus with three columns. The first column represents the ITN class of a word, e.g. *PLAIN* means there is no corresponding ITN class to the word or sequence in the middle column. The second and the last column is the written and spoken form respectively. If there is no difference between written form and spoken form, the last column will be marked as *<self>*. The Google Text Normalization Dataset is generated by a Weighted Finite-State Transducer (WFST), however, it has been treated as a gold standard corpus Inverse Text Normalization task due to the lack of human-labeled corpus for the task.

Fig. 1. Data in Google text normalization dataset

There are multiple attempts in augmenting data for the ITN task in recent years, for example, [1] and [2]. [1] utilizes existing datasets and applies data augmentation strategies for more diversity. However, this method may introduce errors and is constrained by a set of limited augmentation rules. Another method is to use Text-to-Speech (TTS) and Text Normalization (TN) systems[2] to generate spoken form sentences from written forms. This approach is frequently employed in conjunction with existing datasets, such as the supplementary dataset created from publicly available sources as outlined in previous works [3], [4], [5], [6]. The drawback is the performance of TTS and TN systems greatly influences the quality of the generated dataset. Furthermore, the generated dataset is structured at the sentence level, which restricts its utility for advancing further research.

Our study designs and implements an ITN dataset generation pipeline including semi-automatic data source selection and crawling, data pre-processing, and a novel approach for data

[1]available at https://www.kaggle.com/datasets/richardwilliamsproat/text-normalization-for-english-russian-and-polish

alignment as a post-process to achieve the desired ITN dataset. Specifically, we propose to employ a neural network-based word alignment method for the data alignment module. The neural models offer advantages such as the ability to improve performance with data training and eliminate the need for manual rule designing. Our experimental results show that the neural network-based pipeline outperforms the reference rule-based method.

The rest of the paper is organized as follows. Section II explains the proposed pipeline. Section III describes the proposed data alignment approach, and Section IV narrates the experiment setup and training details for the proposed data alignment approach. Section V presents an analysis of the experimental results. Finally, Section VI concludes the work and points out future improvements.

II. Data Preparation Pipeline

Figure 2 depicts the architecture of the pipeline, which consists of three primary stages, i.e. data crawling, data processing, and data alignment. The data crawling stage involves collecting audio and their corresponding written form transcripts. Subsequently, in the data processing stage, an ASR system is utilized to transcribe the audio into spoken form transcripts. Ultimately, in the data alignment stage, the two transcripts are inputted into the word alignment model and aligned to create the written-spoken parallel corpus for ITN. An example of written-spoken forms in the output corpus is shown in Figure 3. The first column presents words in their written form, while the second column is the corresponding spoken form of the words. Words that have no difference between their written and spoken forms are represented as *<self>* in the second column.

In the next subsections, we describe the first two stages in more detail, while the last stage, i.e. Data Alignment with the novel word alignment approach will be presented in Section III.

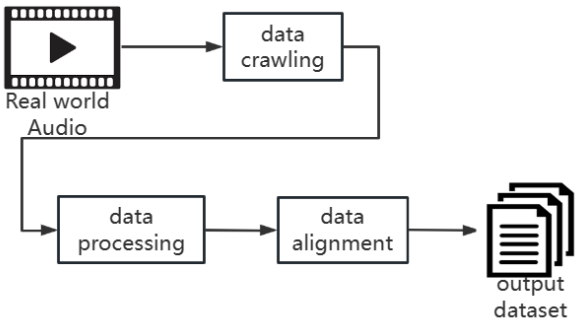

Fig. 2. Overall architecture of the pipeline

A. Data Crawling

A crawler is built to fetch audio and transcripts from web-based sources. The transcripts are equipped with time alignments to the audio and are already converted into their written forms. The transcripts may come in various formats, but predominantly in Web Video Text Tracks (VTT) format

shown in Figure 5. These transcripts are then reformatted into sequences of sentences to simplify future operations.

B. Data Processing

The second stage of the pipeline consists of two primary tasks, re-segmentation and transcript generation, that is to properly segment and transcribe the corresponding audio form of each written transcript obtained in the first stage. Firstly, the written-form transcripts are re-segmented to achieve more appropriate divisions. Subsequently, an ASR system is employed to generate transcripts in the spoken form.

Fig. 7. Example of ASR transcripts

1) Transcript Re-segmentation: The written-form transcripts obtained from the data crawling stage usually lack suitable segmentation as they are primarily intended for on-screen display. Additionally, punctuations are absent from the transcripts. To address this, we attempt to re-segmentation the transcripts using a deep learning toolkit namely Deepsegment[2]. Deepsegment is a segmentation tool that uses neural networks to produce efficient, high-quality segmentation. Importantly, the output from this segmentation process includes starting and ending points of each segment in the audio form, which are beneficial for the second task, i.e. speech recognition.

2) Speech Recognition: To obtain spoken-form transcripts, we employed a fine-tuned WeNet ASR system[7], [8] to transcribe audios. Conventionally, if we send an audio to the system, if it is too long, the ASR system will automatically divide it into segments without considering if a spoken word has been completed. This can be a problem as it may inadvertently split words into two segments. Thus, instead of sending the entire crawled audio to the system, we use the output from the first task to segment the audio correctly. The segmented audio is then inputted into the system to produce the spoken form transcripts. An example of an ASR transcript produced by the Wenet ASR system is displayed in Figure 7.

III. Data Alignment

With the pairs of written and spoken form transcripts that were crawled and generated in the first and second stages respectively, it is now essential to accurately match words at the word level between the pairs to form an ITN corpus. Especially the part where there are differences between the written and spoken forms. This can be done by employing a word alignment approach. Word alignment, also known as bi-text word alignment, which is commonly used in machine translation, seeks to identify potential translations between two texts [9]. It computes the possibility of connections between words and assigns matches if the word pairs translate to each other. Statistical models like Fast Align [10] and GIZA++ [11] were commonly employed in early works and were able to offer satisfaction at certain levels. In recent years, neural-based word alignment models have outperformed their statistical counterparts in numerous bilingual situations. For example, Luong et al. [12] proposed to use force-decoding in a global attention model and achieved competitive results at 34.0 of Alignment Error Rate (AER) for English-German alignment compared with Berkeley Aligner[13]. Kobayashi et al. [14] introduced simple adjustments based on the purposes of attention utilization, Sabet et al. [15] developed Sim Align, Awesome Align that was expanded from Sim Align by Dou et al. [16], and recently, Cross-Align developed by Lai et al. [17].

A. Cross-Align

This work assumes that aligning a written form sequence to its corresponding spoken form is a translation task from one language to another. We adopt Cross-Align [17] for the data alignment stage. Cross-Align is an attention-based method that distinguishes itself from earlier alignment approaches by simultaneously considering source and target language sentences, with a focus on the relationship between two languages. Essentially, Cross-Align accounts for cross-lingual information and leads to performance improvement.

Figure 8 demonstrated the adopted Cross-Align model which consists of three stages. The initial stage independently trains the paired inputs and results in self-attentions that encompass monolingual information for both languages. In the second stage, the monolingual information is exchanged between the languages and leads to the acquisition of cross-attention that carries cross-lingual information. During the final stage, the output embeddings of the two languages are mapped and compared by employing an extraction algorithm. The extraction algorithm works as follows. The similarity between the source and target languages is calculated by taking the dot product of the corresponding cross-attention embedding sequence, yielding similarity matrices. A softmax function is then applied to convert these similarity matrices into probability matrices. Next, a threshold filtration method is used to assign a value of 1 to entries above the threshold and a value of 0 to those below it, generating the final decision metrics. Whenever there is a 1 in the matrix, the two corresponding words should be connected in alignment. The alignment is carried out at the byte pair encoding (BPE) level, as explored in previous studies [18], [19], [20]. Therefore, alignment between source and target words is generated based on these prior works. The output follows the *"Pharaoh format"*, where "i-j" signifies that the i-th word in the source is aligned with the j-th word in the target sentence [21].

[2]Available at https://github.com/notAI-tech/deepsegment/tree/v2

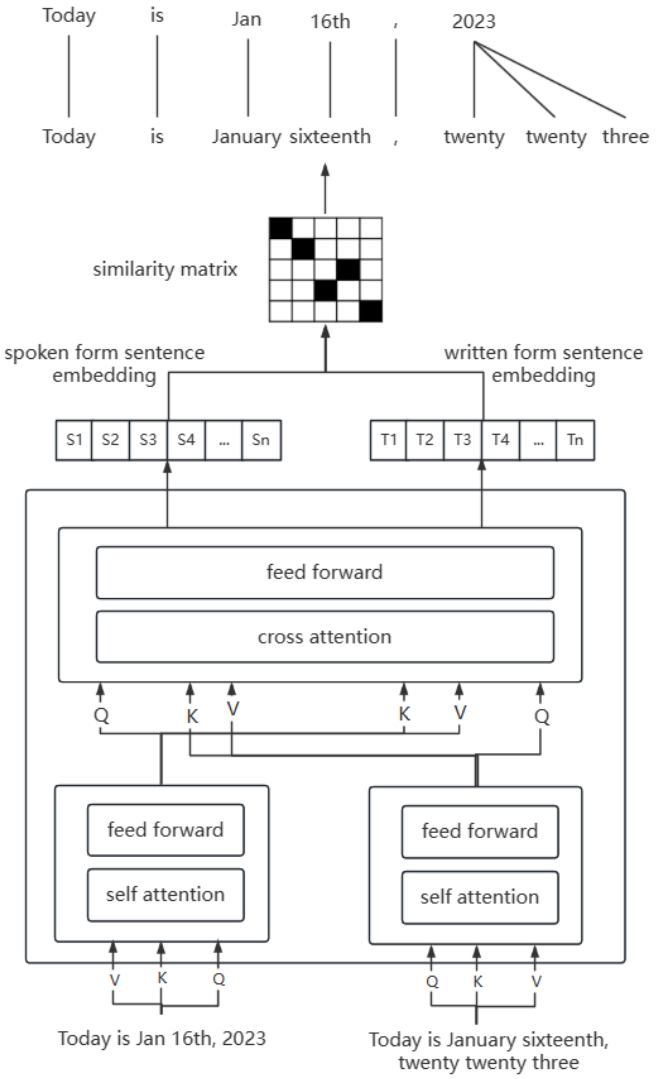

Fig. 8. The proposed Cross-Align model

B. Training Strategy

The training process is divided into two stages to enhance performance. The first stage employs Translation Language Modeling (TLM), a technique designed to learn both monolingual and cross-lingual information. The second stage involves self-supervised alignment, a strategy that fine-tunes the model to better achieve the intended alignment goal.

1) Translation Language Modeling: TLM is a prevalent method utilized in the extraction of monolingual information. Recent research, though, has identified that this approach can also positively impact the learning of cross-lingual information [22]. As a result, the Cross-Align model employs TLM to bridge the gap and enhance understanding between spoken and written forms[17].

The approach involves masking 15% of the input words for the training process, a technique that aligns with previous research[23]. To elaborate, during training, 15% of the words in both spoken and written sentences are selected randomly. Among these chosen words, 80% is substituted with a mask token, 15% is replaced by a random token, and the remaining 5% are left unchanged. The training goal is to predict the words obscured by the mask based on the context provided by the adjacent text. The objective is formally structured in the following way:

$$argmin\lambda_{TLM} = argmin(-logP(x|\hat{x}, \hat{y}, \theta_s, \theta_c) \\ -logP(x|\hat{x}, \hat{y}, \theta_s, \theta_c))$$

In the formula, $\hat{x}$ and $\hat{y}$ represent the masked version of x and y. θ_s and θ_c represent all the parameters in the self-attention module and cross-attention module [17].

2) Self-supervised Alignment: The objective of this stage is to train the model for sentence alignment, as the previous stage focused on predicting masked words rather than the main goal. Consequently, we shift the model's focus to alignment inference. In this training phase, the output from the prior stage serves as the golden dataset, and the model is trained for the word alignment task.

The preceding section made use of the masking technique to acquire both monolingual and cross-lingual information. In contrast, this section reorients the training goal back to alignment production. The model learnt from the preceding section is employed as a pre-trained model. Given that alignment for training isn't always accessible, the training process is designed to be self-supervised. Following the work by Garg et al.[24], the objective is structured as follows:

$$\lambda_{SS} = -\frac{1}{S}\Sigma_{s=1}^{S}\Sigma_{t=1}^{T}G_{st}log(P_{st}^{S}) - \frac{1}{T}\Sigma_{t=1}^{T}\Sigma_{s=1}^{S}G_{st}log(P_{st}^{T})$$

In the equation, S and T are spoken and written form inputs, G indicates alignment label metrics and P stands for connection possibility metrics.

Studies have discovered that the output embeddings from intermediate layers outperform those from the final layer in alignment tasks [16]. As a result, the output from the middle layer of the cross-attention module is leveraged as the word embeddings to enhance the overall performance of the model. To maintain the parameters learnt during TLM, the self-attention and cross-attention layers are frozen in alignment training. Knowledge for alignment is stored and updated within the alignment layers.

IV. Experiment

A. Datasets

We evaluate the proposed alignment approach on two datasets. The first dataset is derived from the Google Text Normalization Dataset. The parallel words within this dataset are organized into parallel sentences to align with the model's input requirements. This dataset is employed for both training and testing the Cross-Align model. Alignments for the testing corpus are generated to assess the model's performance. The format of the data is depicted in Table II.

The second dataset consisting of real-world audio is built by our team to test the performance of the function of the

TABLE II

whole pipeline. The audios are fetched from different public audio and video sharing websites. Considering the difficulty of generating word-level alignment for the parallel sentence, the dataset is only used for testing pipeline performance.

B. Implementation Details

Our implementation primarily follows the Cross-Align paper's guidelines [17]. The model's code is based on Awesome Align developed by Zi-Yi Dou and Graham Neubig [16]. Parameters for the cross-attention module are randomly initialized, while the self-attention module and alignment layer parameters are initialized using the pre-trained mBERT-base model [23]. We employ AdamW as the optimizer, with learning rates $lr_{self} = 5e^{-4}$ and $lr_{cross} = 1e^{-5}$. To expedite training and adapt the model for local environments, we set the batch size to 32. Training occurs on both RTX 3070ti (locally) and NVIDIA Tesla V100 (remotely) GPUs. The self-attention layers are set to 10, and the cross-attention module is set to 2. We train for 3 epochs in the first stage and 2 epochs in the second stage, with thresholds τ set to 0.001 and 0.15, respectively.

The performance of our model is benchmarked against the following approaches:

1) Fast Align [10]. A renowned statistical alignment tool developed by IBM, based on the IBM Model 2 but re-parameterized.
2) GIZA++ [25]. Another notable statistical aligner from IBM. GIZA++ is an extension of GIZA, incorporating various models such as IBM Models 1, 3, 4, and the HMM model.
3) MASK-ALIGN [26]. A self-supervised NMT-based aligner. Unlike other NMT models, MASK-ALIGN considers the target side's context bidirectionally, resulting in improved alignment quality.
4) Awesome Align [16]. A fine-tuned, multilingual, pre-trained language model that enhances its performance by training on parallel data.
5) Rule-based baseline. A WFST-based rule system is proposed as a baseline, with performance improvements achieved through the use of word-level timestamps.

C. Evaluation Metrics

We employed Alignment Error Rate (AER) and Spoken Form Accuracy (SFA) as evaluation metrics to evaluate the proposed alignment approach.

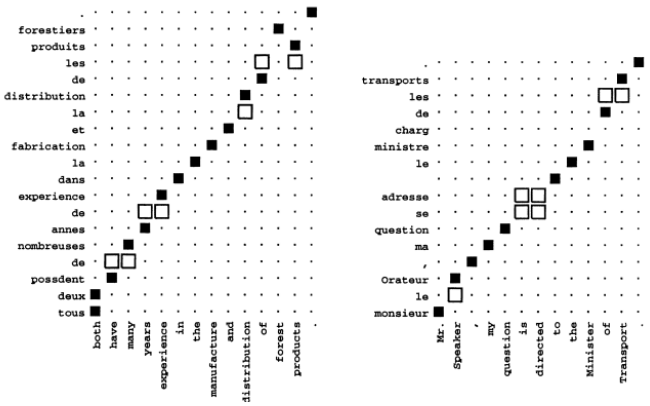

Fig. 9. Example sentence alignment explaining the S(filled squares) and P (unfilled squares)

1) Alignment Error Rate: AER [11] is a widely used evaluating method for word alignment. AER requires standard alignments to compare with and divide the standard alignment into S (sure, robust) alignment and P (possible, ambiguous) alignment. Examples of S and P alignment are illustrated in Figure 9.

Taking in the model output alignment A, the precision and recall are defined as follows:

$$recall = \frac{|A \cap S|}{|S|}$$

$$precision = \frac{|A \cap P|}{|A|}$$

AER is then defined in reference to the F-measure:

$$AER(S, P; A) = 1 - \frac{|A \cap S| + |A \cap P|}{|A| + |S|}$$

AER has a maximum value of 1.0, indicating that when the model's output alignment matches the standard alignment perfectly, it reaches this maximum value. As the disparity between the model's output and the standard alignment increases, the AER value decreases.

2) Spoken Form Accuracy: SFA is designed as an alternative assessment method. Upon the model's generation of alignments for the test set, word pairs involving transformations between spoken and written forms are extracted and sampled. These sampled words are then compared with standard pairs to determine the overall accuracy, denoted as SFA.

$$T_{align} = gen(A, T_{para})$$

$$SFA(T_{align}, P_{gold}) = \frac{extract(T_{align})}{P_{gold}}$$

SFA is does not address sentence structure. instead, it exclusively concentrates on form transformation pairs. A transformation pair is considered correct solely if the transformation is coherent. Incorrectly transformed pairs, including plain word conversions, will contribute to a reduction in SFA value.

V. Result and Analysis

A. Result on Google Text Normalization Dataset

TABLE III
AER result for the different alignment methods on the test set. Better performance is indicated for lower AER.

Method	AER
Fast Align	18.0
GIZA++	12.0
Mask Align	12.8
Awesome Align	12.7
ours	11.8

The results showed on Table III indicates that on spoken-written form text alignment task, our Cross-Align based model performs the best. The Google Text Normalization Dataset is a well-structured and high-quality dataset that possesses significant characteristics. The majority of word pairs in the dataset are identical, as it is primarily composed of plain words. The only distinct pairs are those that involve transformations between spoken and written forms. This straightforward structure carries potent features that statistical models can easily latch onto. For example, the widely used GIZA++ can achieve an AER of 12.0, demonstrating competitive performance when compared to neural methods. While neural methods can also identify these features, they may be more susceptible to noise interference and potentially overlook the primary characteristics. This problem becomes more pronounced when the neural network model is not fully trained. More information can be found in Section V-B.

The AER evaluation method might not precisely represent the performance of models in the experiment. The standard alignment for the test set is derived from the original word-level pairs in the Google dataset. This alignment merely indicates the starting point of the spoken and written forms, and ignores potential associations within the spoken and written form phrases. As a consequence, when the model creates an alignment that partitions these phrases, the AER escalates. Table IV illustrates examples of such intricate connections identified by the model. The model assimilates more detailed features and generates a more accurate alignment. These could be regarded as correctable errors and lead to the possibility that the model's performance might surpass what the AER score suggests.

B. Result on The Real Audio Dataset

The Google dataset is well-organized, allowing inner features to be more prominent. However, this may render it unsuitable for assessment purposes. To test the model with noisier data and realistic situations, the real-world audio dataset is utilized for additional evaluation.

TABLE V
SFA results for the different alignment methods on the real audio dataset. Better performance is indicated for higher numeric word accuracy.

Method	SFA
Fast Align	77.0
GIZA++	83.6
Mask Align	85.2
Awesome Align	85.2
ours (rule based model)	80.3
ours (neural model)	88.5

SFA is selected as the evaluation metric to eliminate the influence of words that are supposed to remain the same. Thus, the transformation between spoken and written forms is the only consideration. The real-world audio test set holds significantly more noise compared to the Google dataset, as illustrated by instances of such inconsistency in Table VI. This issue arises due to the frequently observed discrepancies between parallel transcripts. Although the WeNet ASR is fine-tuned, its performance is not assured under complex scenarios such as the source audios are noisy, and the speakers may have unique accents. The volume of the speaker also significantly impacts the ASR performance. In practice, only the transformation between spoken and written forms is documented in the output dataset, making SFA a suitable evaluation.

Table V presents the SFA results and demonstrates that the

proposed Cross-Align based method exceeds all benchmark baselines in performance. The proposed approach surpasses Awesome Align and proves that the enhancements and alterations made to Cross-Align, built upon Awesome Align, do contribute to the boost in performance. As the test set becomes noisier, GIZA++'s performance fails to remain competitive with neural models. This validates the hypothesis posited in the previous section that a simpler dataset, with its strong features, is amenable to statistical models. This further bolsters our confidence in deploying neural network-based models in the data generation pipeline.

TABLE VII

we we	we we

The proposed method is not without limitations. Text missing can be observed in some instances, as illustrated in Table VII. This issue arises from the incomplete separation of the text. Ideally, for each word in the source text, there should be at least one corresponding link from the target text. However, there are scenarios where the output alignment is not fully segmented into words, indicating that the alignment label for the spoken and written form is imperfect. This could be due to the model being under-trained and affect roughly 4% of the text. The model's inability to generate fine-grained alignment results in the output dataset simply disregarding the unpaired words. While data loss happens during the process, it does not significantly affect the generated dataset as it only leads to minor corpus loss.

VI. CONCLUSIONS

The research concentrates on ITN data generation and aims to create a clean and well-formatted dataset to support ITN research. This area is underdeveloped, as previous studies do not pay much on data quality. The scarcity of publicly available well-constructed datasets for ITN model training and testing is a critical problem. This paper proposed a new approach using ASR systems and word alignment techniques to generate high-quality ITN datasets.

The proposed approach establishes a pipeline to convert audio and transcripts into a word-level written-spoken parallel corpus. The corpus retains a similar format to the Google Text Normalization Dataset. The pipeline involves stages of data crawling, data processing, and data alignment. It employs the WeNet ASR system for audio transcription and the Cross-Align[17] technique for word-level text pairing to enhance the overall performance of the pipeline.

Assessments are carried out using both AER and SFA. On the Google dataset, the proposed method yields an AER of 11.8 and surpasses other benchmarks. On a more complex real-world audio dataset, the method attains an SFA of 88.5, and also outperforms the referenced baselines by at least 3.3%. Despite these results, there is still room for improvement in the pipeline. ITN can be considered data-sensitive and requires high data quality. Consequently, the pipeline needs enhancements to ensure superior data quality. Therefore, further refinements remain crucial.

ACKNOWLEDGMENT

***Abstract*—Effective learning from a small amount of labeled data and a large amount of unlabeled data remains a prominent issue in machine learning. Current semi-supervised learning methods often neglect mismatched problems within class distribution, and do not fully use feature-level encoding for unlabeled data. In this article, we introduce a novel semi-supervised learning method called FSimC, which effectively uses information from unlabeled data at both the semantic- and feature-levels and is successfully applied to mismatched distribution scenarios. At the semantic-level, FSimC consists of two classifiers predicting pseudo and complementary labels for unlabeled data. The mutual alignment of the predictive distributions of the two classifiers results in more accurate pseudo and complementary labels. Then, the two classifiers undergo separate consistency regularization. At the feature-level, we create a cache to store the feature encodings of labeled data. Next, we compute the feature similarity vectors between feature encodings of the weakly and strongly augmented unlabeled data with feature encodings in the cache. Finally, we perform feature similarity consistency on the feature similarity vectors. Extensive experiments are conducted on various benchmark datasets, and the results demonstrate that FSimC achieves outstanding performance in matched and mismatched distribution scenarios. The code is publicly available at *https://github.com/GZHU-DVL/FSimC*.**

I. Introduction

Deep neural networks have achieved impressive performance in various computer vision tasks by leveraging large-scale labeled datasets. However, data annotation is an arduous task that requires substantial manpower, material, and financial investments. Semi-supervised learning (SSL) is a powerful approach that can leverage a small amount of labeled data and a large amount of unlabeled data to train deep neural networks, showing promising research direction.

Recently, some SSL algorithms [1], [2], [3], [4], [5], [6], [7] have greatly improved the performance of the trained models by introducing pseudo labels and distribution alignment. [1] uses consistency regularization, forcing the model to produce the same result for different augmentations of the same unlabeled data. FixMatch [3] introduces a high fixed threshold to filter out unlabeled data with low confidence. To minimize the entropy and push the model predictions away from the decision boundary [8], FixMatch converts the pseudo labels into one-hot vectors. However, during the training, the model showed significant differences in prediction performance for different classes. To address this issue, the dynamic threshold is introduced in [4]. However, these methods focus only on semantic-level information, while [16] successfully uses the information at both semantic-level and feature-level.

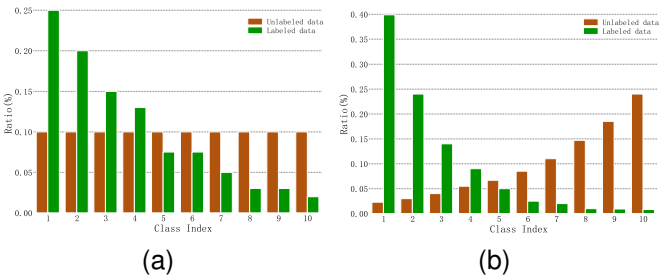

Fig. 1. Illustration of the CIFAR-10 dataset. (a) The distribution of labeled and unlabeled data when the number of labeled data is 40 and $N_{x0} = 40$. (b) The distribution of labeled and unlabeled data when the number of labeled data is 40, $N_{x0} = 40$ and $\gamma_u = 10$.

All the abovementioned methods use the distribution alignment technique. If the distributions of labeled and unlabeled data do not match (i.e., mismatched distribution), as shown in Figure 1, the distribution alignment technique will not work well [2]. RDA [2] proposes a new distribution alignment algorithm that can be applied to mismatched distribution scenarios. However, when using unlabeled data, the information at the feature-level plays a crucial role. Consequently, this vital aspect has not been considered in RDA.

Motivated by the above limitations, this paper develops a novel SSL algorithm called FSimC. At the semantic-level, we introduce the primary classifier ($\mathcal{M}$) and the complementary classifier ($\mathcal{C}$) to predict the pseudo labels and the complementary labels (i.e., not belonging to this class) of unlabeled data respectively, then interact the information of the pseudo labels and complementary labels. At the feature-level, we first establish a cache to store the feature vectors of the labeled data. Then, we calculate the similarity between the feature vectors

979-8-3503-0067-3/23/$31.00 ©2023 IEEE

of weakly and strongly augmented unlabeled data and those stored in the cache, to obtain the weakly and strongly augmented feature similarity vectors. Finally, we perform feature similarity consistency on the weakly and strongly augmented feature similarity vectors to update the convolutional layer. This feature similarity consistency forces the convolutional layer to produce similar feature vectors for the same unlabeled data under different augmentations. Our contributions can be summarized in the following three aspects:

- We propose FSimC, a novel SSL algorithm that successfully leverages semantic and feature information from unlabeled data.
- FSimC achieves similar consistency on the same unlabeled data under different augmentation methods, improving model robustness and forecast prediction accuracy.
- Extensive experiments demonstrate that FSimC can be applied to matched and mismatched distribution scenarios with excellent performance and robustness against disruption.

II. PROPOSED METHOD

In this section, we will introduce FSimC and provide detailed description of our algorithm.

A. Semantic-Level

Denote a batch of B labeled data as $\mathcal{X} = \{(x_b, y_b)\}_{b=1}^{B}$, where $y \in \mathcal{Y} = \{1, \cdots, n\}$ is the ground truth label of x, and n represents the number of categories in the dataset which x belongs to. For the complementary label $\bar{y}$ of x, it is randomly chosen from $\mathcal{Y}/\{y\}$. We perform weak augmentation on labeled data denoted as $w(x)$, then extract feature vector $z = \mathcal{N}(w(x))$ using the convolutional layer. Finally, we feed the feature vector into two different fully connected layers. One called the main classifier ($\mathcal{M}$) to predict the pseudo label ($P_{\mathcal{M}}(z)$), and the other called the complementary classifier ($\mathcal{C}$) to predict the complementary label ($P_{\mathcal{C}}(z)$). Next, we compute the cross-entropy loss $H(\cdot,\cdot)$ between $P_{\mathcal{M}}(z)$ and y, and between $P_{\mathcal{C}}(z)$ and $\bar{y}$, which yields the main supervised loss and the complementary supervised loss, respectively. The main supervised loss is used for the classifier $\mathcal{M}$, while the complementary supervised loss is used for the classifier $\mathcal{C}$:

$$\mathcal{L}_{S\mathcal{M}} = \frac{1}{B}\sum_{n=1}^{B} H\left(y, P_{\mathcal{M}}(z)\right), \mathcal{L}_{S\mathcal{C}} = \frac{1}{B}\sum_{n=1}^{B} H\left(\bar{y}, P_{\mathcal{C}}(z)\right). \tag{1}$$

We employ the unlabeled data to perform consistency regularization on $\mathcal{M}$ and $\mathcal{C}$. Besides, we also take advantage of the interaction between the two classifiers to make the pseudo labels predicted by $\mathcal{M}$ less dependent on the distribution of labeled data, thus alleviating the impact of distribution mismatch. For a batch of unlabeled data $\mathcal{U} = \{(u_b)\}_{b=1}^{B}$ containing B samples, we first apply weak augmentation $w(\cdot)$ and strong augmentation $s(\cdot)$ to them. Then, we use the convolutional layer to extract the feature vectors $z_w = \mathcal{N}(w(u_b))$ and $z_s = \mathcal{N}(s(u_b))$. Finally, we input these feature vectors to $\mathcal{M}$ and $\mathcal{C}$ respectively, to obtain pseudo labels $p_w = P_{\mathcal{M}}(z_w)$, $p_s = P_{\mathcal{M}}(z_s)$, and complementary labels $q_w = P_{\mathcal{C}}(z_w)$ and $q_s = P_{\mathcal{C}}(z_s)$. Next, we perform transpose operation on the pseudo label p_w and the complementary label q_w to obtain their corresponding complementary label $\bar{p}_w$ and pseudo label $\bar{q}_w$:

$$\bar{p}_w = Norm\left(\mathbb{1} - p_w\right), \bar{q}_w = Norm\left(\mathbb{1} - q_w\right), \tag{2}$$

where $\mathbb{1}$ denotes a vector of all-one, and $Norm(\cdot)$ represents the normalization operation which can be expressed as $Norm(x_i) = x_i / \sum_{j=1}^{n} x_j$, $i \in (1, \cdots, n)$. Although we perform transposition operations on p_w and q_w, the relative relationships between classes remain unchanged. Therefore, we can still extract valuable information from $\bar{p}_w$ and $\bar{q}_w$.

Next, we use $\bar{p}_w$ and $\bar{q}_w$ as a guide to scale the predicted vectors of $\mathcal{M}$ and $\mathcal{C}$ (i.e., p_w and q_w):

$$\tilde{p}_w = Norm\left(p_w \times \frac{\mathcal{E}(\bar{q}_w)}{\mathcal{E}(p_w)}\right), \tag{3}$$

$$\tilde{q}_w = Norm\left(q_w \times \frac{\mathcal{E}(\bar{p}_w)}{\mathcal{E}(q_w)}\right), \tag{4}$$

where $\mathcal{E}(\cdot)$ calculates the moving average of the last 128 batches to make the obtained vectors smoother and avoid significant fluctuations caused by outliers, thus enhancing the robustness of the model. Subsequently, to obtain low entropy prediction results, we first calculate $arg\max(\tilde{p}_w)$ to get the one-hot vector $\hat{\tilde{p}}_w$. Then, we use $\hat{\tilde{p}}_w$ as a pseudo label to perform consistency regularization on the main classifier $\mathcal{M}$:

$$\mathcal{L}_{\mathcal{UM}} = \frac{1}{\mu B}\sum_{i=1}^{\mu B} H\left(\hat{\tilde{p}}_{wi}, p_{si}\right). \tag{5}$$

Unlike $\mathcal{M}$, when applying regularization to $\mathcal{C}$, we use the soft label $\tilde{q}_w$ as the complementary label to calculate the cross-entropy loss with q_s:

$$\mathcal{L}_{\mathcal{UC}} = \frac{1}{\mu B}\sum_{i=1}^{\mu B} H\left(\tilde{q}_{wi}, q_{si}\right). \tag{6}$$

In the process of extracting semantic-level information, FSimC does not set any threshold or hyperparameter to filter unlabeled data. Thus, FSimC can exploit all unlabeled data.

B. Feature-Level

In order to extract more valuable information from the data, in addition to using the semantic-level information, we also integrate feature-level information by performing feature similarity consistency in the process of model training. To begin with, we establish a K size cache to store the features of weakly augmented labeled data during the training process as $z_k = \{(z_1, \cdots, z_K)\}$. It should be noted that the feature vectors stored in the cache are continuously updated and follow the first-in-first-out principle.

For a batch of unlabeled data $\mathcal{U}$, the corresponding feature vectors of weakly augmented and strongly augmented versions are denoted as $\left\{\left(z_w^b\right)\right\}_{b=1}^{B}$ and $\left\{\left(z_s^b\right)\right\}_{b=1}^{B}$, respectively. For

the feature vector z_w^b of weakly augmented unlabeled data, we calculate its similarity with each feature vector in the cache to generate its corresponding feature similarity vector, followed by a $soft\max$ operation:

$$Q_w = soft\max\left(sim\left(z_w^b, z_k\right)/t\right), \tag{7}$$

where $sim\left(\cdot,\cdot\right)$ is used to calculate the similarity between two vectors, which can be represented by $sim\left(u,v\right) = uv^T/\left\|u\right\|\left\|v\right\|$. The parameter t is used to control the sharpness of the distribution. Next, we calculate the feature similarity vector between the feature vector of strongly augmented unlabeled data z_s^b with z_k in the same way as above:

$$Q_s = soft\max\left(sim\left(z_s^b, z_k\right)/t\right). \tag{8}$$

Finally, we perform the feature similarity regularization by calculating the cross-entropy loss between Q_w and Q_s:

$$\mathcal{L}_{\mathcal{S}} = \frac{1}{uB}\sum_{b=1}^{uB} H\left(Q_w, Q_s\right). \tag{9}$$

Here, $\mathcal{L}_{\mathcal{S}}$ acts as the convolutional layer to reduce the differences in the feature distributions obtained by this model for the same unlabeled data under different augmentation methods.

C. Overall Loss

Based on the above designs, we can derive the overall loss function:

$$\mathcal{L} = \mathcal{L}_{\mathcal{SM}} + \mathcal{L}_{\mathcal{SC}} + \mathcal{L}_{\mathcal{UM}} + \mathcal{L}_{\mathcal{UC}} + \mathcal{L}_{\mathcal{S}}. \tag{10}$$

At the semantic-level, $\mathcal{L}_{\mathcal{SM}}$ and $\mathcal{L}_{\mathcal{SC}}$ use labeled data to train $\mathcal{M}$ and $\mathcal{C}$ respectively, while $\mathcal{L}_{\mathcal{UM}}$ and $\mathcal{L}_{\mathcal{UC}}$ use unlabeled data to perform regularization operation on $\mathcal{M}$ and $\mathcal{C}$ separately, to address the problem of mismatched distribution. At the feature-level, $\mathcal{L}_{\mathcal{S}}$ uses unlabeled data to perform feature similarity consistency on the convolutional layer.

III. EXPERIMENTS

A. Implementation Details

For all experiments, we use Wide ResNet 28-2 [9] and Wide ResNet 28-8 [9] as the backbone for CIFAR-10 [10] and CIFAR-100 [10], and Resnet-18 [11] as the backbone for STL-10 [12]. We apply RandAugment [13] to strongly augment the unlabeled data. We use SGD [14] as the optimizer, with the weight decay set to 0.0005, the learning rate set to 0.03, and use the decay strategy with cosine learning rate. The model was trained for 1,024 epochs. Unless otherwise specified, we set all loss coefficients to 1 and cache size to K = 1,024 and B = 64.

B. Datasets and Baselines

We evaluate our method on three widely used SSL datasets: 1) **CIFAR-10**, which includes 60,000 32×32 images with 10 classes, each containing 5,000 training samples and 1,000 testing samples. 2) **CIFAR-100**, which is a more complex dataset than CIFAR-10, with 100 classes, 500 training samples, and 100 test samples for each class. 3) **STL-10**, which consists of 113,000 96×96 samples with 10 classes, each having 500 labeled training samples and 800 labeled testing samples. Additionally, there are 100,000 unlabeled samples, including samples outside of these 10 classes, which better reflect the real-world data distribution and can help evaluate the performance of tested SSL methods.

TABLE I
PERFORMANCE COMPARISON ON CIFAR-10, CIFAR-100, AND STL-10 WITH BALANCED, MATCHED Dx AND Du.

	CIFAR-10		CIFAR-100	STL-10
Methods	80 labels	100 labels	1000 labels	1000 labels
MixMatch [7]	80.76%	84.17%	55.32%	63.21%

FSimC	**88.40%**	**32.12%**	**45.29%**	**44.81%**

We adopt six SSL methods as baselines for comparison, including Mixmatch [7], AlphaMatch [15], FixMatch [3], CoMatch [16], RDA [2], and DARP [5], which are representatives of state-of-the-arts.

C. Dx and Du

To demonstrate the effectiveness of FSimC in different data distribution scenarios, we conduct the experiments in the following four cases: 1) The labeled data (Dx) and unlabeled data (Du) are balanced in distributions, and Dx and Du are matched. 2) Dx is imbalanced while Du is balanced, as shown in Figure 1a. 3) Dx is balanced while Du is imbalanced. 4) Dx and Du are both imbalanced and mismatched, as shown in Figure 1b. It is worth noting that when both Dx and Du are imbalanced, Dx is a transposition of Du. This scenario is a more challenging experimental setting that can better evaluate the robustness and generalization ability of the compared methods.

To construct the imbalanced or mismatched Dx and Du scenarios, when the dataset has n classes, we determine the number of labeled data for each class in the following way: $N_{xi} = N_{x0} \times \gamma_x^{-\frac{i-1}{n-1}}, i \in (1, \cdots, n)$. N_{x0} can control the specific number of labeled data for each class. The value of γ_x ensures that $\sum_{i=1}^{n} N_{xi}$ is equal to the total number of labeled data. The number of unlabeled data in each category is: $N_{ui} = N_{u0} \times \gamma_u^{-\frac{i-1}{n-1}}$. In CIFAR-10 and CIFAR-100, N_{u0} is set to 5000 and 500, respectively. The value of γ_u ensures

that $\sum_{i=1}^{n} N_{ui}$ is equal to the total number of unlabeled data in the dataset.

D. Experimental Results

1) Dx and Du are balanced and matched: We test our approach on CIFAR-10, CIFAR-100 and STL-10 with different numbers of labeled data, and compare them with existing baseline methods. As shown in Table I, we can see that FSimC outperforms RDA by 2% on the complex CIFAR-100 dataset. In addition, on the more realistic STL-10 dataset, FSimC is 1.3% better than RDA. In CIFAR-10, we test our method with 10 and 20 labeled data. The result shows that our FSimC achieves higher classification accuracy than the baseline methods. The performance gain of FSimC is due to not only the improved pseudo labels through the interaction between complementary labels and pseudo labels, but also the effective use of the semantic and feature information from all unlabeled data.

2) Imbalanced Dx and balanced Du: Given a fixed total number of labeled data, we adjust the imbalance degree of Dx by varying N_{x0}, while keeping Du balance. We test CIFAR-10 and CIFAR-100 with different values of N_{x0}, and the results are reported in Table II. We can see from Table II that FSimC outperforms other baseline methods in case of mismatched distribution. Especially, when the number of labeled data is 100 and N_{x0} is 80, FSimC exceeds RDA by 9.4% on CIFAR-10. When the number of labeled data is 1,000 and N_{x0} = 80, FSimC respectively exceeds RDA and FixMatch by 3.5% and 4.6% on CIFAR-100.

It can be observed that all SSL methods show a significant decrease in classification accuracy in the mismatched distribution scenario. This is because the traditional consistency regularization requires the match between Dx and Du. While FSimC introduces a new distribution alignment approach at the semantic-level, and performs feature similarity consistency on unlabeled data under different augmentation methods at the feature-level. These strategies improve the accuracy of pseudo labels and the robustness of the model under mismatched Dx and Du, further boosting the performance of FSimC.

3) Dx and Du are imbalanced and mismatched: This is a more challenging test environment, where we conduct experiments on CIFAR-10 and CIFAR-100 under different imbalanced and mismatched distribution settings. The results are shown in Table III. In this more severe mismatched distribution condition, although the accuracy of all the compared methods decreases, FSimC still obtains satisfactory performance and outperforms all the baseline methods.

4) Balanced Dx and imbalanced Du: In this context, we conduct experiments on CIFAR-10, as shown in Table IV. These results show that despite the change in experimental settings, FSimC still achieves excellent performance, and its accuracy surpasses all the baseline methods. This demonstrates that FSimC has great robustness when handling different mismatched distribution scenarios.

5) Mismatched distribution scenario with the DRAP protocol: In different experimental scenarios that meet the DRAP protocol, we conduct experiments on CIFAR-10 and STL-10, and the results are shown in Table V. The experimental results show that FSimC performs excellently in all experimental scenarios, outperforming the DRAP and RDA methods.

E. Ablation Study

In this part, we conduct ablation experiments on the CIFAR-100 by using the Wide ResNet 28-2 as the backbone with a limited set of 1,000 labeled samples to assess the contribution of each component to the proposed FSimC. The experimental results are presented in Table VI. Specifically, we consider different experimental setups, include N_{x0} = 80 or N_{x0} = 40, $\gamma_u = 10$. Notably, we observe varying performance degradation when we remove either the feature similarity

consistency or the interaction between pseudo labels and complementary labels. This observation clearly demonstrates the importance and effectiveness of the individual components within FSimC, highlighting their essential contributions to the overall performance.

IV. Conclusion

In this article, we have presented a new SSL algorithm called FSimC, which efficiently exploits all unlabeled data's semantic- and feature-level information. First, we interact with the distribution information of pseudo and complementary labels at the semantic-level to handle the mismatched distribution scenarios. And at the feature-level, we perform feature similarity consistency on the same unlabeled data under different augmentation strategies, to improve the robustness of the model and further increase its performance in various scenarios. Finally, we conduct extensive experiments with different experimental parameters, and the results show that our FSimC surpasses existing methods in both the matched and mismatched distribution scenarios.

Collaborative Pseudo Labeling for Prompt-Based Learning

Jen-Tzung Chien and Chien-Ching Chen
Institute of Electrical and Computer Engineering, National Yang Ming Chiao Tung University, Hsinchu, Taiwan

***Abstract*—Prompt-based learning has been recently popular as an emerging data efficient approach to parameter fine-tuning for various few-shot classification tasks. The knowledge transfer from a large-scale pre-trained language model could be systematically performed. It is challenging to conduct transfer learning from unlabeled data. Pseudo labeling is feasible to enhance the model generalization by unsupervised learning where additional pseudo labeled data are augmented. However, this method likely suffers from the model bias problem due to the incorrect pseudo labels. This paper presents a new collaborative pseudo labeling for prompt learning which is implemented through a teacher-student model where teacher and student are learned collaboratively. Accordingly, the resulting pseudo labels do not mislead the model while the few-shot classification task can be improved. The experiments on few-shot sentiment classification and natural language inference show the merit of collaborative pseudo labeling and prompt tuning compared with the other methods.**

I. Introduction

In the past few years, the pre-trained language models (PLMs) [1], [2] have been popularly utilized and fine-tuned via supervised methods where the end performance has been significantly advanced for various downstream tasks. An efficient and effective knowledge transfer has been made for the tasks such as natural language inference and machine translation. Basically, the success of these works depend on sufficiency of training data [3]. However, collecting the training samples and their labels is usually time consuming and cost expensive. The real-world tasks likely suffers from the sparseness of labeled data which considerably degrades the performance of supervised learning. To handle these issues, the recent works on prompt tuning [4] based on PLMs have been emerging and receiving numerous attention. Such an approach is feasible to activate the self guided learning via natural language prompt so as to optimize the model capacity. For example, the input sentence "The kids are laughing." with manual prompt template "It is [MASK]" can be converted to the prompt sentence "The kids are laughing. It is [MASK]". Then, the masked language model (MLM) is learned to calculate the blank or mask token [MASK] with a meaningful word which is close to the predefined label word "great" or "good". Recently, a method called better few-shot fine-tuning of language models (LM-BEF) [5] was proposed to implement the prompt tuning for small language models based on BERT [1], [6] and RoBERTa [2] in a way to simulate the concept of in-context learning in the large-scaled model based on the generative pre-trained transformer (GPT-3) [4]. After the prompt tuning with a number of annotated samples, even small language models could achieve the performance comparable with large-scaled model using GPT-3. However, it was difficult to obtain clear improvement by using few-shot supervised data. Accordingly, the rich information from unlabeled data was incorporated to carry out semi-supervised learning in [7], [8]. The resulting implementation was run by using those unlabeled data combined with high-confidence pseudo labels. The generated pseudo labels therefore served as additional supervised data to mitigate the issue of limited data to train generative model [9], [10]. Previously, the pseudo labeling method had an severe problem called the confirmation bias where the incorrect pseudo labels would mislead the model training. In order to address the aforementioned issue, this paper combines the hard prompt tuning driven by the idea of meta pseudo labels (MPL) [11]. A teacher-student framework is introduced to learn the information from pseudo labels so as to improve the supervised performance by using labeled data. Prompt tuning and pseudo labeling are collaboratively performed. The experiments on natural language tasks illustrate the goodness of using this work to cope with the issue of sparse labeled data in text representation.

II. Background Survey

This study presents a new approach to semi-supervised learning where hard prompt tuning is merged with the scheme of pseudo labeling in presence of labeled and unlabeled data.

A. Semi-Supervised Leaning

An inevitable weakness of training a deep neural network is the scarcity of labeled data. The semi-supervised learning [12], [13], [14] has been developed as an emerging and challenging research direction. There have been various methods deployed in real-world applications where the labeled and unlabeled data were both used. A recent method based on the consistency training [15], [16], [17], [7] was proposed to utilize the unlabeled data to enforce the consistency of the model outputs given the similar inputs. The concept of consistency training aims to make prediction of a training sample which is consistent even when data augmentation or noise addition over training data has been done. In order to increase the amount of labeled data for model training, this study leverages the supervision signals offered by labeled data through generation of new pseudo labeled data from unlabeled data. Basically, pseudo labeling [18], [19] focuses on finding the pseudo labels of unlabeled data with high confidence scores which are then augmented in the training dataset for semi-supervised training. Recently, a hybrid model [20], [8] combining the consistency

979-8-3503-0067-3/23/$31.00 ©2023 IEEE

training and pseudo labeling was accordingly developed to improve the performance of semi-supervised learning [21].

B. Prompt-Based Learning

Prompt-based learning is known as an effective approach to enhance model capacity based on a pre-trained language model (PLM) through prompting and learning in a supervised setting. Different from the standard PLM fine-tuning, the prompt tuning is implemented by directly calculating the probability of text data by utilizing PLM. In order to exploit the prior knowledge from PLM, the input sentence $\mathbf{x} = \{\mathbf{x}_1, \cdots, \mathbf{x}_L\}$ is transformed to form a prompt sentence $\mathbf{x}_{\text{prompt}}$ with a hard prompt template $\mathcal{T}(\cdot)$ with the masked token [MASK] as

$$\mathbf{x}_{\text{prompt}} = \mathcal{T}(\mathbf{x}) = \{\mathbf{x}, \text{It is } [\text{MASK}]\}. \tag{1}$$

After obtaining the hidden representation $\mathbf{h}_{[\text{MASK}]}$ of prompt sentence $\mathbf{x}_{\text{prompt}}$ by using PLM, the masked language model has to predict the word distribution which should fill the masked token with the correct word v in vector $\mathbf{w}_v$ by using

$$p([\text{MASK}] = v|\mathbf{x}_{\text{prompt}}) = \frac{\exp(\mathbf{w}_v^T \cdot \mathbf{h}_{[\text{MASK}]})}{\sum_{v' \in \mathcal{V}} \exp(\mathbf{w}_{v'}^T \cdot \mathbf{h}_{[\text{MASK}]})}. \tag{2}$$

The verbalizer $\mathcal{M} : \mathcal{Y} \rightarrow \mathcal{V}$ is the mapping from the task label space $\mathcal{Y}$ to individual words in vocabulary space $\mathcal{V}$ which are masked [22], [23]. The distribution of predicting the word label $v \in \mathcal{M}(y)$ can be expressed by using the prompt-based language model with parameter θ in a form of

$$\begin{aligned} p_\theta(y|\mathbf{x}) &= p_\theta([\text{MASK}] = \mathcal{M}(y)|\mathbf{x}_{\text{prompt}}) \\ &= \sum_{v \in \mathcal{M}(y)} p_\theta([\text{MASK}] = v|\mathbf{x}_{\text{prompt}}). \end{aligned} \tag{3}$$

The objective for prompt-based learning is seen as a classification problem where language model parameter θ is fine-tuned by minimizing the cross-entropy loss

$$\mathcal{L}_{\text{prompt}}(\mathbf{x}, y, \theta) = -\sum_{y \in \mathcal{Y}} y \log p_\theta(y|\mathbf{x}). \tag{4}$$

III. Pseudo Labeling & Prompt Tuning

This study carries out a semi-supervised scheme based on pseudo labeling which is implemented for prompt tuning and learning in a number of natural language tasks. In general, prompt tuning is exploited to estimate the masked language model head so as to predict the words behind the masked tokens. Such a process is similar to the fine-tuning process in training a standard classifier. This paper would like to incorporate pseudo labeling in prompt tuning and language modeling where a teacher-student framework is built with two masked language model heads. The overall system architecture is illustrated in Figure 1 which is detailed in what follows.

A. Teacher-Student Framework for Pseudo Labeling

A teacher-student framework is built to carry out pseudo labeling for prompt-based learning where semi-supervised learning is performed by using the labeled and unlabeled data. A pre-trained language model (PLM) is utilized and

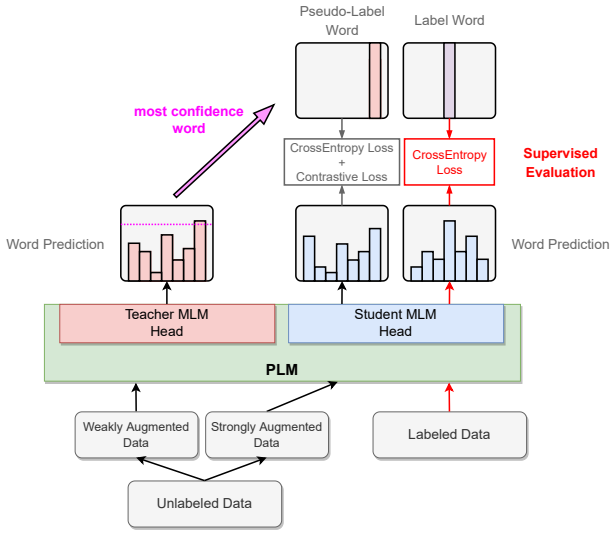

Fig. 1. Overview of semi-supervised learning via pseudo labeling where the teacher-student MLM heads in a pre-trained language model are estimated by prompt-based learning.

the masked language model (MLM) heads for a teacher and a student are configured on top of PLM. These two MLM heads are estimated through prompt-based learning. In the process, the weakly and strongly augmented data from unlabeled samples are first collected and then fed in PLM to find the predicted words of masked tokens in prompt-based representation from the teacher and student MLM head, respectively. On the other hand, the student MLM head is also utilized to predict the masked tokens by using the labeled sentences. The prompt-based cross-entropy loss from the head outputs is minimized to conduct a supervised evaluation from purely labeled data. In particular, another cross-entropy loss, which is calculated from the outputs using weakly and strongly augmented data, is minimized to perform an unsupervised evaluation from purely unlabeled data. The predicted words of the masked tokens from the weakly augmented sentences with the highest confidence scores are treated as the pseudo labels for a kind of collaborative learning [24], [25] under a teacher-student framework. The learning is performed to pursue the *label consistency* from the head outputs of teacher and student MLMs. Teacher MLM head is learned to provide the pseudo labels corresponding to the unlabeled sentences which are utilized to learn the student MLM head. In what follows, the optimization problem is formulated.

B. Objectives from Unlabeled and Labeled Data

In this study, the PLM $\mathcal{F}_\phi$ with the pre-trained parameters ϕ is acted as a feature extractor or encoder. The controllable parameters include the masked language model heads for teacher f_{θ_t} and student f_{θ_s} which are seen as the classifier layers for word prediction of masked tokens. Let the hidden representation ofthe weakly augmented data of the unlabeled prompt input $\mathbf{x}_{\text{prompt}} \sim \mathcal{D}_u$ be calculated by using the PLM-

based feature extractor as

$$\mathbf{h}_{[\text{MASK}]} = \mathcal{F}_\phi(\mathbf{x}_{\text{prompt}}). \tag{5}$$

This representation is then used to predict the pseudo label $\widehat{y}_{\theta_t}$ of a masked token based on MLM scheme via

$$\widehat{y}_{\theta_t} = \underset{i}{\text{argmax}} f_{\theta_t,i}(\mathbf{h}_{[\text{MASK}]}) \tag{6}$$

where $f_{\theta_t,i}$ denotes the output node of teacher MLM head corresponding to i^{th} vocabulary word. The strongly augmented data from unlabeled data $\mathbf{x}_u \sim \mathcal{D}_u$ are fed to PLM by using the student MLM head f_{θ_s} where the overall prompt-based cross-entropy loss is calculated by

$$\mathcal{L}_{\text{prompt}}(\mathcal{D}_u, \theta_s) = \sum_{n=1}^{|\mathcal{D}_u|} \mathcal{L}_{\text{prompt}}(\mathbf{x}_u^{(n)}, \widehat{y}_{\theta_t}^{(n)}, \theta_s) \tag{7}$$

where n is the sample index. Notably, the pseudo labels from teacher MLM head $\{\widehat{y}_{\theta_t}^{(n)}\}$ are used. Then, the student MLM head θ_s is estimated according to the stochastic gradient descent (SGD) algorithm with a learning rate α

$$\theta_s' = \theta_s - \alpha \nabla_{\theta_s} \mathcal{L}_{\text{prompt}}(\mathcal{D}_u, \theta_s). \tag{8}$$

The pseudo labels $\{\widehat{y}_{\theta_t}^{(n)}\}$ does affect the supervised evaluation of student MLM head by using the labeled data $\mathbf{x}_l \sim \mathcal{D}_l$. The updated student parameter θ_s' always depends on the teach parameter θ_t through its relation to pseudo labels $\{\widehat{y}_{\theta_t}^{(n)}\}$. The prompt-based cross-entropy loss from labeled data $\mathcal{D}_l = \{\mathbf{x}_l^{(n)}, y_l^{(n)}\}$ is therefore calculated by

$$\begin{aligned} &\mathcal{L}_{\text{prompt}}(\mathcal{D}_l, \theta_s') = \sum_{n=1}^{|\mathcal{D}_l|} \mathcal{L}_{\text{prompt}}(\mathbf{x}_l^{(n)}, y_l^{(n)}, \theta_s') \\ &\text{where} \quad \theta_s'(\theta_t) = \theta_s' \end{aligned} \tag{9}$$

C. Optimization and Implementation

This study aims to improve the supervised evaluation of using student MLM head through a scheme called collaborative pseudo labeling (CPL) where the teacher MLM head provides the pseudo supervision. A constrained optimization problem is then formulated and expressed by

$$\begin{aligned} &\min_{\theta_t} \ \mathcal{L}_{\text{prompt}}\left(\mathcal{D}_l, \theta_s(\theta_t)\right) \\ &\text{subject to} \ \ \theta_s'(\theta_t) = \underset{\theta_s}{\text{argmin}} \ \mathcal{L}_{\text{prompt}}(\mathcal{D}_u, \theta_s). \end{aligned} \tag{10}$$

To facilitate the teacher-student learning framework, the idea of meta learning for pseudo labels [11] is merged to rewrite the optimization problem as an unconstrained optimization.

$$\begin{aligned} &\min_{\theta_t} \ \mathcal{L}_{\text{prompt}}(\mathcal{D}_l, \theta_s'(\theta_t)) \\ &= \min_{\theta_t} \ \mathcal{L}_{\text{prompt}}(\mathcal{D}_l, \theta_s - \alpha \nabla_{\theta_s} \mathcal{L}_{\text{prompt}}(\mathcal{D}_u, \theta_s)). \end{aligned} \tag{11}$$

In the implementation, the gradient of the prompt-based loss with respect to the teacher MLM head θ_t can be derived as

$$\begin{aligned} &\nabla_{\theta_t} \mathcal{L}_{\text{prompt}}(\mathcal{D}_l, \theta_s - \alpha \nabla_{\theta_s} \mathcal{L}_{\text{prompt}}(\mathcal{D}_u, \theta_s)) \\ &= -\alpha \nabla_{\theta_s} \mathcal{L}_{\text{prompt}}(\mathcal{D}_l, \theta_s') \nabla_{\theta_t} [\nabla_{\theta_s} \mathcal{L}_{\text{prompt}}(\mathcal{D}_u, \theta_s)] \\ &= -\alpha \nabla_{\theta_s} \mathcal{L}_{\text{prompt}}(\mathcal{D}_l, \theta_s') \nabla_{\theta_s} \mathcal{L}_{\text{prompt}}(\mathcal{D}_u, \theta_s) \\ &\quad \times \nabla_{\theta_t} \mathcal{L}_{\text{prompt}}(\mathcal{D}_u, \theta_t) \triangleq g_t(\mathcal{D}_l, \mathcal{D}_u). \end{aligned} \tag{12}$$

The double gradient term in Eq. (12) with the defined function $g_s(\widehat{y}_{\theta_t}) = \nabla_{\theta_s} \mathcal{L}_{\text{prompt}}(\mathbf{x}_u, \widehat{y}_{\theta_t}, \theta_s)$ can be derived as

$$\begin{aligned} &\nabla_{\theta_t} \mathbb{E}_{\mathbf{x}_u \sim \mathcal{D}_u, \widehat{y}_{\theta_t} \sim f_{\theta_t}(\mathbf{x}_u)} [\nabla_{\theta_s} \mathcal{L}_{\text{prompt}}(\mathbf{x}_u, \widehat{y}_{\theta_t}, \theta_s)] \\ &= \mathbb{E}_{\mathbf{x}_u \sim \mathcal{D}_u, \widehat{y}_{\theta_t} \sim f_{\theta_t}(\mathbf{x}_u)} [\nabla_{\theta_t} g_s(\widehat{y}_{\theta_t})] \\ &= \mathbb{E}_{\mathbf{x}_u \sim \mathcal{D}_u, \widehat{y}_{\theta_t} \sim f_{\theta_t}(\mathbf{x}_u)} [g_s(\widehat{y}_{\theta_t}) \nabla_{\theta_t} \widehat{y}_{\theta_t}] \\ &= \mathbb{E}_{\mathbf{x}_u \sim \mathcal{D}_u, \widehat{y}_{\theta_t} \sim f_{\theta_t}(\mathbf{x}_u)} [g_s(\widehat{y}_{\theta_t}) \nabla_{\theta_t} \log p(\widehat{y}_{\theta_t} | \mathbf{x}_u, \theta_t)] \\ &= \mathbb{E}_{\mathbf{x}_u \sim \mathcal{D}_u, \widehat{y}_{\theta_t} \sim f_{\theta_t}(\mathbf{x}_u)} [g_s(\widehat{y}_{\theta_t}) \nabla_{\theta_t} \mathcal{L}_{\text{prompt}}(\mathbf{x}_u, \widehat{y}_{\theta_t}, \theta_t)] \end{aligned} \tag{13}$$

which is obtained by considering the prompt-based loss using cross-entropy loss. The gradient over teacher MLM head θ_t is finally derived as a product of three gradients. Therefore, CPL is implemented by a learning procedure as shown in Algorithm 1. The feedback from teacher MLM head via the pseudo labels $\widehat{y}_{\theta_t}$, is received to jointly update the student and teacher heads $\{\theta_s, \theta_t\}$.

Algorithm 1: Collaborative pseudo labeling for prompt-based language models.

Require: $\{\mathcal{D}_l, \mathcal{D}_u\}$: labeled and unlabeled training dataset. B: batch size. I: no. of iterations. ϕ: PLM parameters. $\{\theta_t, \theta_s\}$: teacher and student MLM head parameters. $\{\alpha, \beta\}$: learning rates of student and teacher heads.

for $i = 0, \ldots, I-1$ **do**

- sample labeled batch $\{\mathbf{x}_l^{(n)}, y_l^{(n)}\}_{n=1}^B \sim \mathcal{D}_l$
- sample unlabeled batch $\{\mathbf{x}_u^{(n)}\}_{n=1}^B \sim \mathcal{D}_u$
- sample pseudo labels $\widehat{y}_{\theta_T}^{(n)} \sim p(\widehat{y}_{\theta_T}^{(n)} | \mathbf{x}_u^{(n)}, \theta_t)$
- compute student loss with pseudo labels $\mathcal{L}_{\text{prompt}}(\mathcal{D}_u, \theta_s) = \sum_{n=1}^B \mathcal{L}_{\text{prompt}}(\mathbf{x}_u^{(n)}, \widehat{y}_{\theta_t}^{(n)}, \theta_s)$
- update student $\theta_s' \leftarrow \theta_s - \alpha \nabla_{\theta_s} [\mathcal{L}_{\text{prompt}}(\mathcal{D}_u, \theta_s)]$
- compute teacher loss $\mathcal{L}_{\text{prompt}}(\mathcal{D}_l, \theta_s - \alpha \nabla_{\theta_s} \mathcal{L}_{\text{prompt}}(\mathcal{D}_u, \theta_s))$
- compute teacher gradient $g_t(\mathcal{D}_l, \mathcal{D}_u)$ in Eq. (12)
- update teacher $\theta_t' \leftarrow \theta_t - \beta g_t(\mathcal{D}_l, \mathcal{D}_u)$

end

IV. Experiments

A. Experimental Settings

In the experiments, the proposed collaborative pseudo labeling (CPL) was evaluated for a number of public-domain down-stream tasks including sentiment classification using the Stanford sentiment treebank (SST-2 for two classes and SST-5 for five classes) [26], the customer review (CR) [27], the movie review (MR), the subjectivity (Subj) and natural language inference using the multi-genre NLI (MNLI), the Stanford NLI (SNLI), and the question answering NLI (QNLI). The standard settings in various public-domain datasets were adopted. For comparative study, the related methods including the standard fine-tuning (FT), the LM-BEF [5] and the state-of-the-art prompt-based few-shot learner (SFLM) [28] were carried out. The accuracy was reported in the comparison. The semi-supervised learning was evaluated by examining the

performance by tuning the ratio between unlabeled and labeled data, denoted by μ. Here, k denotes the number of labeled instances per class. Batch size B is 10. AdamW optimizer [29] was used. The learning rates α and β were both set as 10^{-5}. In the experiments, the PLM using BERT with 100M number of parameters is also fine-tuned in the learning process. The computation overhead of calculating teacher-student MLM heads relative to fine-tuning the whole BERT model [1] was only 3.5%. The ablation studies on the effects of supervision, data efficiency, latent visualization and attention score were assessed in various sets of comparison.

CPL	**62.9**	**69.2**	**61.5**

B. Experimental Results

First of all, the classification accuracies of using FT, LM-BEF, SFLM and the proposed CPL in the tasks of SST-2, SST-5, CR, MR and Subj are shown in Table I. The results of MNLI, SNLI and QNLI are reported in Table II. The absolute and consistent improvements over state-of-the-art method SFLM [28] 0.4%, 0.4%, 1.9%, 0.3% 0.1%, 0.3%, 1.8% and 0.5% in the tasks of SST-2, SST-5, CR, MR, Subj, MNLI, SNLI and QNLI are obtained, respectively. In what follows, a set of ablation studies are conducted to evaluate various effects in the learning procedure based on the proposed CPL.

C. Ablations and Analysis

1) Effect of supervision: In this ablation study, the effect on the number of labeled data N in the performance of semi-supervised learning is examined. Table III shows the results of few-shot learning with N to be 20, 100, 1000 on SST-2 and MNLI. For SST-2, the total number of training examples is 6920. The case of using N=20 for fine-tuning PLM and estimating teacher-student MLM heads is relatively few. In this set of experiments, the number of unlabeled examples was fixed as 800. It is obvious that increasing number of labeled examples significantly raises the classification accuracy in different tasks. However, the ratio between unlabeled and labeled data also affects the end performance. The results shown in Tables I and II were the case of using 100 labeled and 800 unlabeled samples.

TABLE III
ACCURACY (%) ON SST-2 AND MNLI TASKS. N DENOTES THE NUMBER OF LABELED DATA FOR MODEL TRAINING.

Model	N	SST-2	MNLI
CPL	20	90.9	61.2
CPL	100	91.4	62.9
CPL	1000	93.7	83.0

2) Effect of data efficiency: This work uses labeled data and unlabeled data to learn for few-shot natural language classification tasks. However, the amounts of labeled and unlabeled data are required in the joint training is an issue. There are four sentiment classification tasks (SST-2, SST-5, CR and MR) analyzed in this evaluation. Figure 2 illustrates the performance of CPL with different combinations of k and μ. It is found that the error rate reduces as μ increases. This implies that the proposed CPL can work better with the increasing number of unlabeled samples. But, the performance improvement in SST-5 task is not significant. The benefit of increasing the amount of supervision is obvious. With the increase of labeled data, the error rate of all four tasks reduces significantly. The model is truly sensitive to the number of labeled data. The hyperparameters k=16 and μ=4 are fixed hereafter.

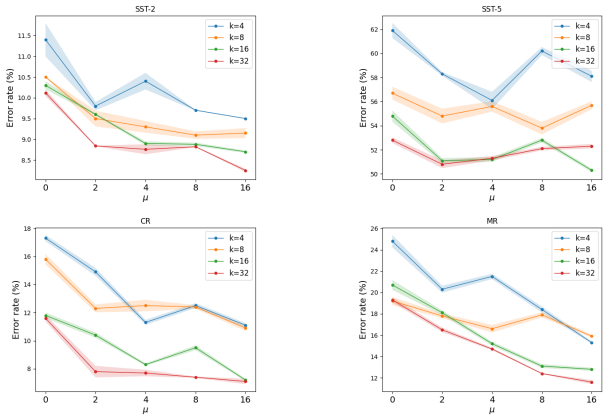

Fig. 2. Classification error rate (%) of using CPL under different numbers of instances per class k and ratios between unlabeled and labeled data μ where four tasks are evaluated.

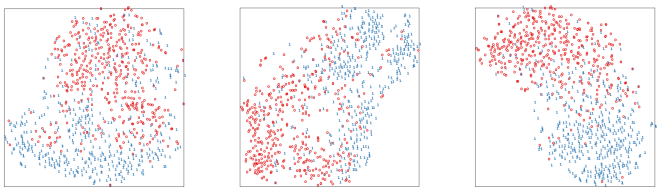

Fig. 3. Comparison of visualization of latent representations via t-SNE by using different models in presence of two classes.

3) Latent representation: In addition, Figure 3 shows the latent visualizations by using t-distributed stochastic neighbor embedding (t-SNE) among three methods where SST-2 task is evaluated. This comparison shows the visualization of latent embeddings or a kind of latent semantics for two classes as shown by red and blue. Here, the samples of special token [CLS] as a kind of class information for original input sentences are used. This token took from the final layer of PLM. For the prompt sentences, the embeddings of masked token [MASK] from the masked language model are used to predict the masked words in prompt-based fine-tuning. It can be seen that CPL and SFLM obtain better separation of two classes compared with FT. Latent representation using CPL look more separate than that using SFLM.

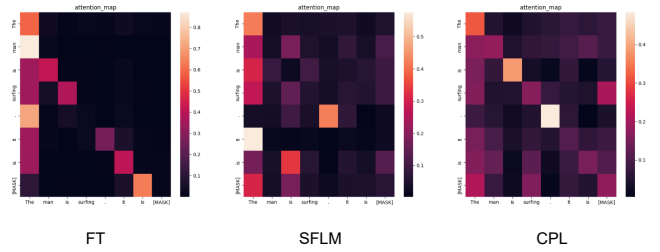

Fig. 4. Comparison of attention scores on SST-2 task.

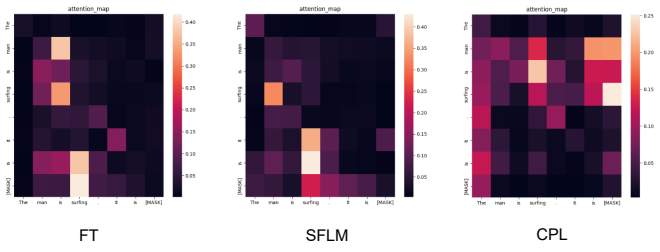

Fig. 5. Comparison of attention scores on SST-5 task.

4) Attention Analysis: The comparison of FT, SFLM and the proposed CPL is further extended to that for attention analysis. Figures 4 and 5 draw the attention maps of three methods for an example of sentence "The main is surfing. It is [MASK]" where SST-2 and SST-5 tasks are evaluated, respectively. These results show that CPL are more attentive to the masked token [MASK] (the right most token or column in the map) than FT and CPL.

V. Conclusions

This paper has presented the collaborative pseudo labeling for prompt-based learning, which was feasible to jointly learn the pseudo label words from the unlabeled data and improve the supervised evaluation of labeled data simultaneously. The experiments on a number of sentiment classification and natural language inference tasks showed that the potential improvement compared with fine-tuning method and state-of-the-art method could be achieved. Such an approach based on the teacher-student framework is able to be employed together with other methods to learn the pseudo label words from the unlabeled data so as to improve the supervised evaluation of labeled data simultaneously.

***Abstract*—Prompt-based learning is powerful to utilize the large-scaled pre-trained language model (PLM) for language understanding where the input sentences are augmented by either adding the hard prompt using word tokens or the soft prompt in a form of trainable tokens. However, the learned soft prompt in training domain may not really help a frozen PLM to handle domain shift in test domain. This paper presents an approach to incorporate meta learning into domain adaptation to train new soft prompt which sufficiently generalizes the frozen PLM to a number of domains. The meta soft prompt is then developed for few-shot unsupervised domain adaptation where a frozen PLM can be quickly adapted to a target domain. This soft prompt is optimized according to meta learning where the domain adaptation loss and the prompt-based classification loss are jointly minimized. The experiments on multi-domain natural language understanding show the benefits of the proposed meta soft prompt in pre-trained language model by using BERT under the few-shot setting.**

***Index Terms*—Meta learning, few-shot learning, prompt tuning, domain adaptation, language model**

I. Introduction

Traditionally, deep neural networks were trained by supervised learning and have achieved desirable performance in a variety of speech and language tasks [1]. Recently, self-supervised or unsupervised schemes have been successfully developed to improve the end performance even without additional training data. A famous example is the bidirectional encoder representations from transformers (BERT) [2] which is a pre-trained language model [3], [4] based on transformer [5] learned from a large corpus based on the unsupervised tricks consisting of the masked language modeling and the next sentence prediction. PLMs have been further extended to boost the performance of challenging tasks by enhancing the model capacity with very limited controlled parameters through utilizing the adapter learning [6] or model reprogramming [7]. With the emerging of the powerful generative pre-trained transformer like GPT-3 [8] or ChatGPT, it becomes crucial to conduct the cutting-edge research on how to utilize the pre-trained model for various downstream tasks via prompt-based learning or tuning. In general, the previous PLMs did not handle the issue that specific domain of input sentences is unseen and far from those in training sentences. The performance of PLMs will drop drastically. This phenomenon known as the domain shift is common in practice [9], [10]. The larger the domain shift, the higher the influence on the end performance. In addition, collecting a large amount of labeled data over a variety of domains is difficult and time-consuming. The unknown domain is hard to predict.

To activate fast learning in multi-domain language modeling, this study focuses on zero-shot or few-shot domain adaptation for prompt-based learning where there is few data or even no training data provided in target domain. This paper further copes with the issue of sub-optimal performance in domain adaptation which is caused by inconsistent objectives in both pre-training and fine-tuning stages [11], [12]. In order to address the aforementioned issues, this work proposes the so-called meta soft prompt to enhance the adaptability of PLM to an incoming target domain. In addition to domain adaptation [13], this method is designed by considering two learning paradigms. The first one is the soft prompt learning which converts the actual word tokens in hard prompt into some real-valued vectors as the continuous tokens in augmented input sentence. Prompt optimization is based on gradient updates by using the labeled data [14], [15]. Compared to the hard prompt, soft prompt looks more attractive since both specific domain expertise and trial-and-error process can be avoided [16], [17], [18]. The second one is the model-agnostic meta learning (MAML) [19], [20] which is performed to address the adaptability of soft prompt across multiple domains. A gradient-based meta learning algorithm [21], [22] is implemented to estimate the parameters of meta learner through a set of task-specific learners for individual learning over various meta-training tasks. In this paper, each individual meta-training task is treated as an unsupervised domain adaptation problem which is tackled by learning the soft prompt from source-domain labeled data as well as target-domain unlabeled data. After completing the meta training across diverse meta-training tasks, the trained meta soft prompt is feasible to smoothly adapt to any incoming target domain with a few unlabeled data. In the experiments, the competitive result is obtained by using the proposed prompt-based language model for multi-domain sentiment classification.

II. Soft Prompt & Domain Adaptation

A. Prompt-based language model

Pre-trained language models (PLMs) have shown convincing results in recent years. To leverage the benefit of PLM, the task-specific layer or head was added on top of PLM to adjust the PLM parameters to a specific downstream task. More recently, prompt-based learning is recognized as a powerful method to improve the fine-tuning of PLM after GPT-3 [8]

979-8-3503-0067-3/23/$31.00 ©2023 IEEE

has been publicly released. This method allows training a model with a cloze-style input sentence which adds a textual string prompt to original sentence that has some unfilled slots. The resulting language model needs to predict the word for unfilled slots instead of predicting the class label. Due to the success of GPT-3, such a learning scheme was further introduced to employ smaller PLMs [16], [17], [18] by fine-tuning the pre-trained model. Using this approach, hard prompt is formed by a string of "discrete" word tokens from the vocabulary. But, determining a suitable prompt for a specific domain or task requires the domain expertise and needs many trial-and-errors. Although hard prompt template is fixed, the PLM and the masked language model (MLM) head should be fine-tuned for a downstream task. Alternatively, the soft prompt was constructed in the continuous space with good adaptability. Since the soft prompt $(v_1 v_2 \ldots)$ can be easily updated by gradient descent, the optimal prompt is obtained in a handcraft-free way. Using soft prompt, the parameters of PLM and MLM head are frozen. Only the soft prompt tokens are estimated. Relative to fine-tuning and hard prompt, the number of controlled parameters in soft prompt is greatly reduced. Figure 1 compares the hard (left) and soft (right) prompt-based language models.

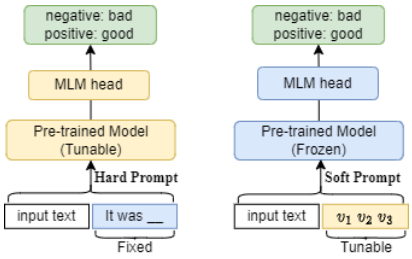

Fig. 1. Hard and soft prompts using pre-trained models.

B. Domain adaptation

In general, fine-tuning, hard prompt or soft prompt using PLM only works well for a specific test domain, and could not easily handle the diverse input sentences which may come from a variety of domains in practical scenarios. As a result, the researches on unsupervised domain adaptation (UDA) [23], [24] have become crucial for handling multi-domain tasks. UDA aims to mitigate the issue of domain shift caused by different distributions from source and target data where the class labels of adaptation data in target domain are missing. Previously, UDA was employed in BioBERT [25] where the pre-training phase was continued by adaptation using domain-specific data. In [26], UDA was performed by simultaneously running the domain-specific pre-training as well as task-specific pre-training by using task-specific unlabeled data [27]. The learned representation was closer to task distribution. In [28], UDA through language model was recently proposed and implemented by combining MLM task and downstream task where the model robustness and the sample efficiency were improved during the adaptation to target domain. Nevertheless, there is existing a difference between the pre-training objective for PLM task and the fine-tuning objective for downstream task, which may constrain the utilization of knowledge based on PLM [11]. This study introduces UDA to adapt the soft prompt across different domains via meta learning in accordance with a consistent hybrid objective for domain adaptation and prompt learning.

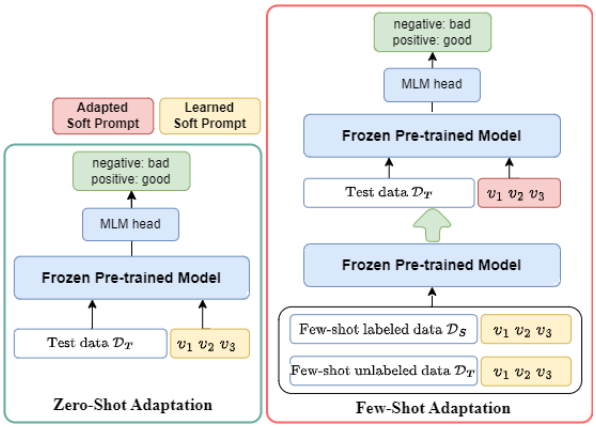

Fig. 2. Soft prompt language models with zero-shot and few-shot domain adaptation where the frozen PLM is used.

C. Joint soft prompt and few-shot domain adaptation

In this paper, soft prompt learning is collaborated with unsupervised domain adaptation where zero-shot and few-shot settings are considered as illustrated in Figure 2 where the frozen PLM is utilized and the labeled data in target domain $\mathcal{D}_T$ are missing. The left-hand-side subfigure shows the zero-shot adaptation where there is no additional adaptation data. Only the test sentence in target domain is provided. Soft prompt is updated by using test data. On the other hand, the right-hand-side subfigure displays the scenario of joint soft prompt estimation and few-shot domain adaptation. In this scenario, there are two stages where the frozen PLM is both applied. The first stage is to learn soft prompt where the labeled data in source domain $\mathcal{D}_S$ and the few-shot unlabeled data in target domain $\mathcal{D}_T$ are provided for prompt-based learning. Then, the second stage is to further adapt the soft prompt by using the test sentence in target domain. To cope with multi-domain tasks, such an adaptive soft prompt is hereafter estimated through meta learning.

III. Few-Shot Learning & Meta Soft Prompt

In practical situation, the input query is usually originated from various domains. It becomes crucial to develop a general solution to soft prompt across different domains and present a fast adaptation scheme to a new domain where multi-domain tasks are handled. The underlying idea of this paper is to enhance the adaptability of soft prompt language model to a new target domain where meta learning or learning to learn is performed to acquire multi-domain knowledge from a number of tasks which are designed to solve the problem on hands.

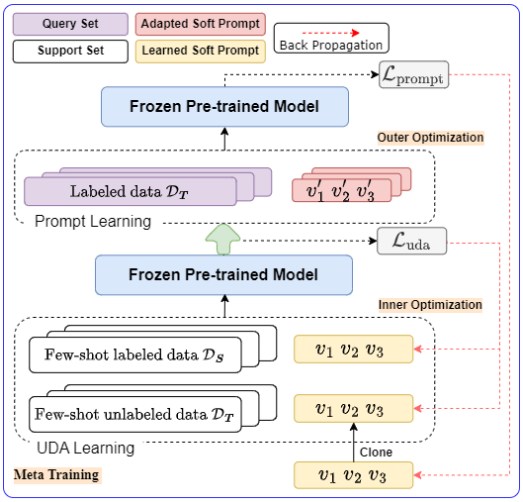

Fig. 3. Multi-domain learning for meta soft prompt language model via few-shot unsupervised domain adaptation (UDA).

A. System overview and meta learning

This study presents the model agnostic soft prompt for few-shot domain adaptation. An overview of the proposed method is shown in Figure 3. There are three parts in the learning process including input data, soft prompt and PLM using BERT. Input data contain *support set* and *query set*. In meta training, *support set* is used to update the prompt parameters of learner (v_1, v_2, v_3). *Query set* is then used to calculate the gradients for updating the parameters of learner (v_1, v_2, v_3) followed by updating the parameters of meta learner (v_1', v_2', v_3'). Soft prompt is treated as the trainable parameters, and is appended to an input sequence and a mask token denoted by [MASK]. PLM is responsible to encode the input sentence and extract the features of mask token. These features are used to calculate MLM head outputs which are employed to measure the probability distribution over vocabulary words to implement the meta soft prompt language model. Unlike traditional meta learning approaches [19], which train the whole model from a large number of few-shot classification problems to allow the model to quickly adapt to the unseen few-shot classification tasks, the proposed meta learning framework aims to tackle domain shift issue by introducing soft prompt learning conditioned on a frozen PLM. All of the meta-training tasks are designed to simulate the scenarios which will be encountered during test stage. Therefore, the frozen PLM is feasible to generalize multiple source domains to a target domain by only tuning the parameters of soft prompt.

B. Soft prompt language model

Soft prompt language model adopts a soft prompt template consisting of a set of trainable vectors that are added to the input sentence as the description of target task. The label words are defined as the highest probability words that PLM will predict. In a binary sentiment classification task, the input sentence is formed by L words as $\mathbf{x} = \{x_1, \cdots, x_L\}$ and the corresponding label is $y \in \mathcal{Y} = \{\text{positive}, \text{negative}\}$. Given the template function $T(\cdot)$, the input sentence $\mathbf{x}$ can be converted to a MLM input to BERT-based PLM, $\mathbf{x}_{\text{prompt}} = T(\mathbf{x} = \{e(\mathbf{x}), v_1, \cdots, v_k, e([\text{MASK}])\})$, where the $e(\cdot)$ is the embedding function of PLM $\mathcal{F}$. For the label words, a verbalizer $\mathcal{M} : \mathcal{Y} \mapsto \mathcal{V}^*$ is given to map the label space to a set of label words $\mathcal{V}^* \subset \mathcal{V}$, where $\mathcal{V}$ is the vocabulary of $\mathcal{F}$. Then, we can treat $\mathcal{F}$ as a function of mapping $\mathbf{x}_{\text{prompt}}$ to a vocabulary distribution of mask token as $p(\mathcal{V}_y(\mathbf{x}_{\text{prompt}})) = \mathcal{F}(\mathbf{x}_{\text{prompt}}) \triangleq \mathbf{v}_{\text{mask}}$. The conditional likelihood of the predicted label word $y^* \in \mathcal{V}_y^*$ with respect to mask token given $\mathbf{x}_{\text{prompt}}$, $p(\mathcal{V}_y^* \leftarrow [\text{MASK}]|\mathbf{x}_{\text{prompt}}, \theta)$, is yielded by

$$p(y^*|\mathbf{x}_{\text{prompt}}, \theta) = \frac{\exp(\mathbf{v}_{\text{mask}}(\mathcal{V}_y^*))}{\sum_{y' \in \mathcal{Y}} \exp(\mathbf{v}_{\text{mask}}(\mathcal{V}_{y'}^*))} \tag{1}$$

where $\mathbf{v}_{\text{mask}}(\mathcal{V}_y^*)$ denotes the probability of label word $\mathcal{V}_y^*$ in the vocabulary distribution $\mathbf{v}_{\text{mask}}$. The overall training objective for soft prompt learning is expressed by a cross-entropy loss as

$$\mathcal{L}_{\text{prompt}}(\mathbf{x}, y, \theta) = -\sum_{y' \in \mathcal{Y}} y' \log p(y^*|\mathbf{x}_{\text{prompt}}, \theta) \tag{2}$$

where θ denotes the trainable parameters for soft prompt.

C. Unsupervised domain adaptation

Unsupervised domain adaptation as shown in Figure 3 implements the inner optimization that adapts the soft prompt language model to a target domain. This study presents an approach to UDA by combining soft prompt learning and masked language modeling using labeled data from source domain $\mathcal{D}_S$ and unlabeled data from target domain $\mathcal{D}_T$. The soft prompt (v_1, v_2, v_3) in UDA is updated by using the objectives for masked language model $\mathcal{L}_{\text{mlm}}$ (via cross-entropy loss for predicting mask tokens) and soft prompt $\mathcal{L}_{\text{prompt}}$ where the unlabeled data $\mathcal{D}_T$ and labeled data $\mathcal{D}_S$ are adopted, respectively. The adapted soft prompt is able to simultaneously capture the target domain information from MLM objective and the task language knowledge from prompt objective. UDA objective is built as $\mathcal{L}_{\text{uda}} = \mathcal{L}_{\text{prompt}} + \lambda \mathcal{L}_{\text{mlm}}$ with a hyperparameter λ. α is implemented via the popular optimizer using AdamW.

D. Nested optimization procedure

The overall learning and adaptation for meta soft prompt are performed via a nested loop. In the inner loop, the learners start with the parameters of meta learner and update the parameters based on $\mathcal{L}_{\text{uda}}$ by using *support set* in each meta-training task. In the outer loop, the meta learner is optimized according to the performance of those learners evaluated on *query set* in each meta-training task. The whole process is repeated until reaching convergence. Parameter updating for learners is expressed as

$$\theta_i' = \theta - \alpha \nabla_\theta \mathcal{L}_{\text{uda}}(\mathcal{D}_i^{\text{sup}}, \theta), \quad 1 \le i \le m. \tag{3}$$

$\mathcal{D}_i^{\text{sup}}$ represents the *support set* of meta-training task $\mathcal{T}_i$. Meta learner $\widehat{\theta}$ is estimated by minimizing the prompt loss over

Algorithm 1: Meta soft prompt learning & adaptation

individual learners θ_i'. Meta learning is performed across various meta-training tasks $\mathcal{T}_i$ sampled from $p(\mathcal{T})$

$$\widehat{\theta} = \arg\min_{\theta} \sum_{\mathcal{T}_i} \mathcal{L}_{\text{prompt}}(\mathcal{D}_i^{\text{qry}}, \theta - \alpha \nabla_\theta \mathcal{L}_{\text{uda}}(\mathcal{D}_i^{\text{sup}}, \theta)). \quad (4)$$

$\mathcal{D}_i^{\text{qry}}$ represents the *query set* of $\mathcal{T}_i$. The overall learning and adaptation of meta soft prompt is shown in Algorithm 1. This procedure is a kind multi-task learning over various domains.

IV. Experiments

The proposed meta soft prompt language model was evaluated for multi-domain text classification by using the FDU-MTL dataset [29] which is known as a challenging dataset consisting of 16 domains, as shown in Table III, which were broadly categorized into Amazon product reviews and movie reviews. In the evaluation, one domain was chosen as target domain, and the remaining domains were seen as source domains. A binary sentiment classification with the classes of positive and negative for reviews was performed. Classification accuracy was reported in different sets of evaluation.

A. Evaluation for latent visualization

First, the goodness of meta soft prompt language model for unseen domain data is evaluated. Figure 4 compares 2-D visualization using t-SNE [30] for latent representation of the mask tokens by using the prompted data in 'books' reviews. Basically, the mask tokens using the proposed language model are separate in the classes of positive and negative reviews, and are domain-matching in source and target domains. In the experimental setting, the soft prompt length 5 was used and λ=0.8 was fixed.

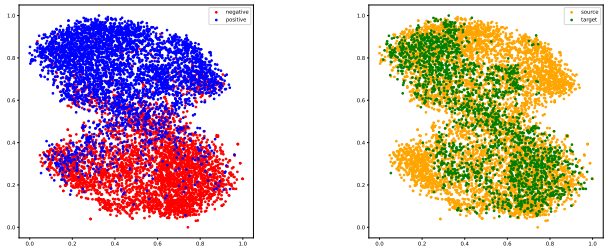

Fig. 4. Visualization on reviews of 'books' target domain using the proposed meta soft prompt. (left) Positive and negative reviews are in blue and red, and (right) source and target domain reviews are in orange and green, respectively.

TABLE I
Accuracy (%) on 4 domains of FDU-MTL dataset. Number in brackets shows the soft prompt length (S).

Domain	**FT**	**SP** (2)	**MSP** (2)	**SP** (5)	**MSP** (5)
books	80.8	**85.2**	83.6	86.8	**88.0**
DVD	79.3	83.2	**83.4**	84.4	**85.6**
electronics	79.4	82.1	**82.6**	84.8	**85.1**
kitchen	79.5	84.5	**86.2**	86.1	**87.6**

B. Evaluation for document classification

The proposed meta soft prompt (MSP) is further compared with traditional fine-tuning (FT) method and the previous soft prompt (SP) [14]. The experiments on review or document classification were conducted on four domains: books, DVD, electronics and kitchen. For a fair comparison, the number of learned parameters were set identically in all methods. For the conventional fine-tuning, the number of trainable parameters in the task-specific layer 768×2 was chosen. As a consequence, the length of soft prompt (S) was set to 2 as each prompt was encoded as a 768-dimensional word embedding. The case S=5 is also evaluated. The accuracy is shown in Table I which indicates that the proposed MSP outperforms FT and SP in various domains especially when the soft prompt length S is increased to 5.

TABLE II
Accuracy (%) and number of trainable parameters (N) for the methods with/without UDA using S=10 with 4 or 8 shots. MoE-Tr [10] requires a large-scaled trainable model.

Domain	MoE-Tr	SP	MSP	SP-4	MSP-4	MSP-8
books	90.0	87.5	**88.6**	87.9	88.7	**89.0**
DVD	89.3	86.2	**86.9**	87.0	**88.5**	88.1
electronics	90.6	87.4	**88.4**	87.9	89.2	**90.3**
kitchen	90.8	88.5	**89.8**	89.2	90.5	**90.7**
UDA	yes	no	no	yes	yes	yes
N	264M	7.68K	7.68K	7.68K	7.68K	7.68K

In Table II, the comparison is extended to a recent work called the transformer-based multi-source domain adaptation (MoE-Tr) [10], which introduced a mixture of experts by using multiple trainable PLMs in adaptation where the number of trainable parameters is N=264M. MoE-Tr performed the domain adversarial learning [31] where many shots were used. Instead, MSP has N=7.68K and only adopts one single frozen

PLM. Unsupervised domain adaptation works for SP and MSP. The improvements by increasing shot number and soft prompt length are obtained.

TABLE III
ACCURACY (%) ON 16 DOMAINS OF FDU-MTL DATASET.

Domain	MT-DNN	ASP-MTL	MAN-L2	MAN-NLL	BERT	MSP
books	82.2	84.0	87.6	86.8	87.0	**89.0**
DVD	84.2	85.5	88.1	**88.6**	85.6	88.1
electronics	81.7	86.8	87.4	88.8	88.3	**90.3**
kitchen	80.7	86.2	89.8	89.9	91.0	**90.7**
apparel	85.0	87.0	87.6	87.6	90.0	**92.0**
camera	86.2	89.2	**91.4**	90.7	90.0	90.8

AVG	84.3	86.1	88.2	88.4	88.1	**89.5**

Next, the proposed MSP language model is compared with the previous multi-task learning methods over various domains of FDU-MTL dataset. The experiments were setup by choosing one domain as the target for testing and the remaining domains as the sources for training. After the meta training on different source domains is done, the learned meta soft prompt is adapted to a target domain by using 8 shots of unlabeled reviews. The adapted meta soft prompt is collaborated with the frozen PLM to conduct evaluation on the target domain. The results are shown in Table III. These results are consistently compared with strong baselines including the multi-task deep neural network (MT-DNN) [32], the adversarial multi-task learning (ASP-MTL) [29], the multinomial adversarial network with the least square loss (MAN-L2), the negative log-likelihood loss (MAN-NLL) [33], and the BERT model [2] which is fine-tuned on each domain. ASP-MTL [29] used abundant unlabeled samples from the target domain. Instead, MSP only adopted 8 unlabeled samples for domain adaptation. The results reveal that MSP obtains the highest averaged accuracy in most of domains.

V. CONCLUSIONS

This paper has presented the meta soft prompt language model with few-shot domain adaptation. The learned meta soft prompt was appended to input data and adapted to different domains by using the frozen pre-trained model with few-shot unlabeled samples in target domain. The results have shown that the meta soft prompt could successfully boost a frozen pre-trained model to capture domain-specific information and achieved desirable results by only training a few parameters. For future work, the proposed method could be integrated with other unsupervised domain adaptation in the inner optimization for meta learning. Furthermore, the proposed method is feasible to collaborate with not only masked language model but also sequence-to-sequence model or autoregressive model.

***Abstract*—Advancements in satellite imaging catalysed exploratory leaps in Earth observation activities. The high spatial and temporal resolution of remotely sensed imagery aid land use land cover identification , cropland monitoring, change detection and disaster management. However, keeping the quality of these observations is still a challenge. The presence of obstacles, such as clouds and aerosols, usually impairs observations from space, and this is not desirable for computer-based applications as they rely hugely on the available data. The cloud removal problem has been studied for decades, but the randomness in the presence and type of cloud made reconstruction tasks challenging. Fusing Synthetic Aperture Radar (SAR) auxiliary information with optical imagery guided the cloud reconstruction problem. The proposed work introduces a Multi-Scale Deep Fusion Network (MSDF-Net) that learns the spatial and temporal dependency from seen samples and removes clouds from multispectral Sentinel-2 observations. The network extracts physical properties from the SAR auxiliary data and aids the cloud-free reconstruction. The proposed method shows its capability to remove both thin and thick clouds. The network is trained, tested, and validated on the SEN12MS-CR dataset, a global real cloud-removal dataset consisting of triplets of Sentinel-2 cloudy, Sentinel-2 cloud-free and Sentinel-1 SAR data. The network is compared against state-of-the-art techniques and found to exhibit superior performance.**

I. Introduction

The spatial-spectral data gathered from remote sensing satellites play a significant role in earth observation applications such as natural resource management, land use land cover classification, weather forecasting etc. The main challenge faced by space-borne optical frequency imaging is the presence of abundant and random clouds in the earth's atmosphere. Thick clouds block the ground observation entirely, whereas thin clouds allow partial visibility. In any case, these anomalies in reflectance products affect the quality and quantity of temporal observations. There is no guarantee that the subsequent observations can provide cloud-free data because of the uncertainty of cloud presence in the earth's atmosphere. Statistical studies on 12 years of Moderate Resolution Imaging Spectroradiometer (MODIS) observations reveal that the global cloud distortion is 67%, whereas landmass cloud distortion is 55% [1]. The spatial data analysis of the Brazilian Amazonian Landsat archive from 1984 to 1997 also uncovered that cloud cover degrades the accuracy of land observations and complicates biogeophysical understandings. The increasing need for quality temporal land observations accelerated the efforts to design an optimal cloud removal technique.

Spatial filtering was introduced as the preliminary technique for removing clouds from optical data. [2] studied the atmospheric cloud's spatial-frequency properties, resulting in the design of various Homomorphic Filtering (HF) schemes for removing clouds from Landsat data. A modified moving averaging method that replaces cloud pixels with the average value of cloud-free ensemble points was proposed [3]. The Harmonic ANalysis of Time Series (HANTS) algorithm perform Fourier analysis to generate the cloud mask and performs temporal interpolations with the aid of remaining observations to generate a cloud-free composite [4].Another advancement in the research's approach was the idea of image enhancement for quality improvement [5]. The filtering techniques are based on the assumption that the land cover change is negligible for subsequent satellite revisits.

Cloud removal methods based on classical machine learning approaches, such as Regression Trees, Expectation Maximization (EM), Support Vector Machines (SVM), Support Vector Regression (SVR), and Multioutput Support Vector Regression (MSVR), Independent Component Analysis (ICA), came into the picture [6][7][8]. However, these techniques failed to accommodate spectral characteristics. The spatially weighted linear regression on spatiotemporally selected similar pixels succeeded in integrating complementary information from spectral bands [9]. The shortcomings of Haze-Optimized Transformation (HOT) to discriminate haze over bright land surfaces were resolved by the Iterative HOT (IHOT) based on multivariate regression [10]. A Noise-Adjusted Principal Component Transform (CR-NAPCT) outperformed all the existing

979-8-3503-0067-3/23/$31.00 ©2023 IEEE

PCA and ICA techniques [11].

Inpainting approaches consider global and local neighbourhood relationships to restore the deteriorated portions of a given image. Early inpainting techniques based on Bandelet transform [12] and Dictionary-based learning [13] only study spatial relationships. Later the inpainting technique incorporating the spatial, spectral and temporal dependencies evolved [14]. The selection of the most suitable pixels for gap filling is the main challenge of inpainting methods and can be tackled with the help of auxiliary data [15].

The emergence of deep learning enabled the analysis of massive volumes of remotely sensed data, and several automated cloud detection and removal methods have been successively introduced. The Deep residual symmetrical concatenation network (RSC-Net) with an encoder-decoder architecture successfully removed haze from Landsat-8 OLI observations [16]. Multi-spectral Generative Adversarial Networks (GANs) and Attention-based GANs surpass conventional GANs in encoding spatial dependencies and channel relationships [17] [18].However, robust deep learning on spectral data is challenged by the issues of limited samples and higher dimensionality [19][20][21].

The longer wavelength characteristics of microwave sensors make SAR imagery resistant to clouds, dust and adverse climatic scenarios such as heavy rainfall and cyclones . Advancements in multi-sensor data fusion techniques enabled scientists to extract complementary spatial-spectral information from SAR and optical data [22]. [23] came up with a unified Spatial-Temporal-Spectral Convolutional Neural Network (STSCNN). They fused multisource information but failed to extract SAR-guided physical properties. An extension of existing conditional GANs (cGANs) performed cloud removal by learning the corresponding SAR data and temporal cloud-free optical data [24]. The first encoder-decoder architecture fusing Sentinel-1 SAR and Sentinel-2 multispectral optical data has an architecture of U-Net with three encoders and one decoder [25]. Pixel-Level merging of temporal optical sequence and SAR observations performed using a hybrid ConvLSTM+cGAN network [26]. They secured a better pixel-wise restoration of cloudy data.

The state-of-the-art deep learning based data fusion assisted cloud removal techniques include c-GAN [27], Simulation-Fusion GAN [28], DSen2-CR [29], and GLF-CR [30]. The deep learning methods in literature use different variations of convolutional neural networks (CNN) but fail to extract information from all available spectral dimensions at multiple scales. These techniques are trained and validated on simulated or limited datasets, which questions the model's generalizability in addressing real-world scenarios. GANs based models in the literature are complex to train and have the identical drawback of generalizability. This research paper addresses existing techniques' shortcomings and proposes a fusion based multi-scale deep convolutional neural network for multispectral cloud removal. The significant contributions of this work are:

1) Introduces a multi-scale SAR-optical fusion-based deep CNN that extracts non-linear features for automated cloud removal.
2) The dilated convolutions in the proposed model increase the receptive field without any added overhead on computational complexity and extract intrinsic features
3) The proposed cloud-constrained loss function derived from novel cloud map evaluates loss by giving weightage to cloudy pixels and improving model fitness

The remainder of the paper is organised as follows. The proposed multi-scale SAR-optical fusion-based deep convolutional neural network is explained in Section II, and the experimental setup and results are covered in Section III. Finally, the article is summarised in Section IV with insightful remarks.

II. Proposed Methodology

A. Dilated Convolution

One major drawback of CNNs is the failure to perform global processing and extract contextual information from the scene. The solution is to use larger filters or stack up more hidden layers. Both these techniques increase the total number of trainable parameters and impose overheads in computational complexity and generalization capability. The dilated convolution inflates the kernel, expands the receptive field according to the dilation rate, and helps capture more contextual information. The output y_{mn} of a 2D dilated convolution with a dilation rate of d on input x and kernel k is given in (1).

$$y_{mn} = f\left(\sum_{r}\sum_{i=0}^{h-1}\sum_{j=0}^{w-1} k_{ij}x_{(m-d*i)(n-d*j)} + b_{mn}\right) \quad (1)$$

The dilation operation causes exponential growth in the receptive field in each network level by a power of 2 ($d = 2^l$, where l is the level of network). For example, if $d = 4$, the dilations will be performed on two levels. The receptive field of dilated convolution at different levels is derived by (2), where $l_0 = 1$ by default.

$$l_i = l_{i-1} + (k-1)d \quad (2)$$

B. Cloud-Shadow Map Generation

Segregating the cloud and shadow regions of an image is critical for the proposed cloud reconstruction methodology. The generated Cloud-Shadow Map(CM) guides the cloud removal method to reconstruct only the cloud-shadow-affected regions actively. The cloud and shadow map are found separately and later merged to produce a combined cloud-shadow map . The physical and reflectance properties of cloud and shadow are exploited to generate a cloud-shadow map.

Cloud map generation: Cloud map is generally constructed considering High-Reflectance, Normalized Difference Moisture Index (NDMI), and Normalized Difference Snow Index (NDSI) characteristics [31]. Initially, all pixels of the image are considered cloudy and cloud map is initialized to 1 ($\Psi = 1$). Subsequently, the update procedure verifies whether each pixel is covered by clouds or not. The cloud map construction is based on the min-max normalized Sentinel-2 TOA data. Cloud

has high reflectance, and hence cloudy pixels usually appear bright. These high reflectance characteristics are extracted from Coastal aerosol, Blue, Green, Red and Cirrus bands of Sentinel-2 data. The high reflectance-based update Ψ_{HR} is computed for each pixel by sequentially replacing the previous cloud map with the values derived from (3).

$$\begin{aligned} \Psi &= min(R_{\downarrow}(B2)_{[0.1:0.5]}, Cloud\ Map) \\ \Psi &= min(R_{\downarrow}(B1)_{[0.1:0.3]}, \Psi) \\ \Psi &= min(R_{\downarrow}(B10)_{[0.5:0.7]}, \Psi) \\ \Psi_{HR} &= min(R_{\downarrow}(B2+B3+B4)_{[0.2:0.8]}, \Psi) \end{aligned} \tag{3}$$

The existing cloud map generation methods consider only NDMI as an index to approximate water contents and produce reliable cloud identification over a complete vegetation area. However, this approximation fails for diverse regions of vegetation and water bodies. This research work incorporates NDWI as an alternative index, which uses the GREEN-NIR combination to effectively identify cloudy pixels in such mixed regions [32][33]. The proposed NDWI-based cloud map update is given in (4).

$$\Psi_{NDWI} = min\left(R_{\downarrow}\left(\frac{B3-B8}{B3+B8}\right)_{[-1:1]}, \Psi_{HR}\right) \tag{4}$$

The NDMI index is considered for cloud detection for moist pixel approximation. NDMI-based cloud pixel evaluation is carried out as follows.

$$\Psi_{NDMI} = min\left(R_{\downarrow}\left(\frac{B8-B11}{B8+B11}\right)_{[-0.1:0.1]}, \Psi_{NDWI}\right) \tag{5}$$

Snow-based assumptions are also crucial for discriminating cloudy pixels. The effect of condensed water particles in the cloud reflected in NDSI, and NDSI-based cloud map update is done as follows.

$$\Psi_{NDSI} = min\left(R_{\downarrow}\left(\frac{B3-B11}{B3+B11}\right)_{[0.8:0.6]}, \Psi_{NDMI}\right) \tag{6}$$

The rescaling operation $R_{\downarrow}$ performs a pixel remapping and is defined by the rescaling in the range [l, u]. Equation (7) remaps the pixel value Ψ in the [l, u] range.

$$\Psi_{R_{\downarrow}} = \frac{\Psi - l}{u - l} \tag{7}$$

The updated cloud map undergoes opening and closing morphological operations with a 3×3 structuring element for accurate cloud filling. The opening operation removes any isolated high reflectance responses from highly bright surfaces such as building rooftops, whereas the closing operation fills the random gaps and cracks within high bright cloud map regions. The resulting cloud map undergoes rescaling to the range [0,1] and a binary thresholding with a threshold of $T_a = 0.2$ to produce the final cloud map. The final cloud map update is given as

$$\Psi = \begin{cases} 1, & if \quad \Psi > T_a \\ 0, & otherwise \end{cases} \tag{8}$$

Shadow map generation: The procedure takes the same min-max normalized Sentinel-2 TOA image as the input. The low reflectance characteristics and low NDVI characteristics are considered to generate a shadow map. The proposed shadow map generation algorithm distinguishes the cloud shadow from other materials by utilizing Coastal aerosol, NIR, SWIR-1 and SWIR-2 bands [31][34]. The algorithm identifies low reflectance pixels by thresholding ($T_b = 0.75$) the average value of bands B1, B8, B11 and B12 . These low-reflectance pixels are further discarded from the shadow map if they exhibit lower NDVI values ($T_c = 0.8$), assuming those are dark pixels generated due to water presence. The thresholds T_a, T_b and T_c are selected from the empirical cloud detection studies conducted for Sentinel-2 multispectral data [34]. A closing morphological operation is performed to close gaps in shadows and generate a final shadow map. The NDVI computation and shadow map update Φ are derived from (9) and (10).

$$NDVI = \frac{B8-B4}{B8+B4} \tag{9}$$

$$\Phi = \begin{cases} 1, & \left(\frac{B1+B8+B11+B12}{4}\right) < T_b\ AND \\ & NDVI < T_c \\ 0, & otherwise \end{cases} \tag{10}$$

The cloud map and shadow map undergo pixel-wise OR operation to produce a combined cloud-shadow map . Fig. 1 portray the flowchart for the complete cloud-shadow map generating process.

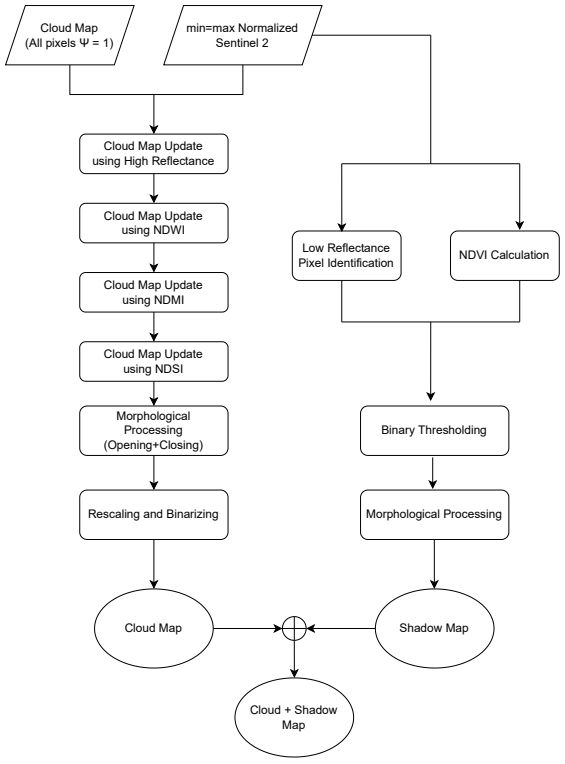

Fig. 1: Combined Cloud-Shadow Map Generation Process

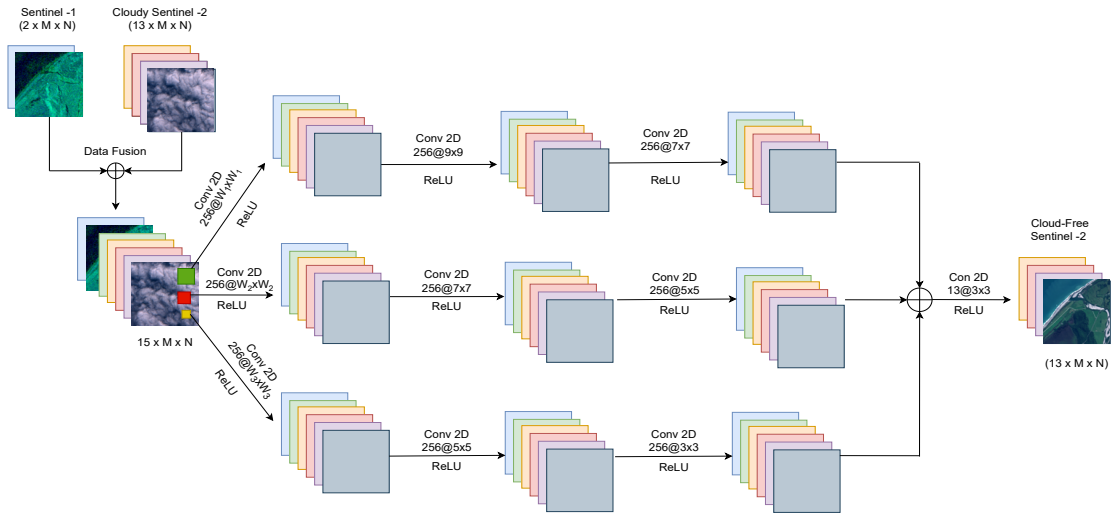

Fig. 2: Proposed MSDF-Net Cloud Removal Architecture

C. Cloud Constrained Loss Function

L_1 loss is a robust loss function commonly used for regression and reconstruction problems [35]. The learning algorithms try to minimize the L_1 loss, which is the total of all absolute differences between the actual and reconstructed pixel values. The L_1 loss function is given in (11), where X, Y stand for the reference and reconstructed images, whereas N denotes the total number of observations.

$$L_1 = \frac{\sum_{i=1}^{n} |X_i - Y_i|}{N} \tag{11}$$

However, the L_1 loss alone cannot guarantee a reliable reconstruction because the L_1 loss is computed for the total image without giving any weightage for the cloud and shadow-affected regions. The uncloudy reference observations are usually captured in temporal revisits of the satellite, and there is no guarantee that the landscape will remain the same during the revisit. Therefore, retaining all available cloud-unaffected information of the optical input data is critical. Since the reconstruction happens only for the cloud-shadow-affected region, an explicit regularized novel loss function comprising the previously generated cloud-shadow map is proposed. The proposed cloud-constrained loss function L_{ccl} is defined as

$$L_{ccl} = \frac{\sum_{i=1}^{n} CM \cdot |X_i - Y_i|}{N} + \frac{\sum_{i=1}^{n} |X_i - Y_i|}{N} \tag{12}$$

The first part of L_{ccl} selectively evaluates loss by giving weightage to cloudy pixels and improve model fitness . The second part of the equation is the actual L_1 loss, that act as a regularization term that deal with overfitting.

D. Proposed Model

The auxiliary information in the form of SAR guides the cloud reconstruction process by providing useful texture and geophysical information. The proposed MSDF-Net cloud removal utilizes the Sentinel-1 SAR information as the complimentary data for missing region reconstruction. Both Sentinel-1 and Sentinel-2 data are 3D cubes of sizes $B \times M \times N$, where B represents the number of bands and M, N denotes the spatial dimensions. A channel-wise concatenation of the Sentinel-1 VV, VH bands with all the available 13 bands of Sentinel-2 is performed to produce a fused input of size $15 \times M \times N$ and given as input to the model. Multi-scale feature extraction is the core concept of the proposed model, where each convolution branches extract feature maps using variable window sizes. The model is designed to have three convolution branches with varying window sizes, W_1, W_2, and W_3, respectively. Each convolution branch performs two additional sequential 2D convolutions. Branch-1 perform the 2D sequential convolutions with kernels of sizes 9×9 and 7×7. Branch-2 engage convolution kernels of sizes 7×7 and 5×5, whereas 5×5 and 3×3 convolutions are carried out in Branch-3. The model is designed to extract 256 feature maps at each convolution and employs Rectified Linear Unit (ReLU) as an activation function. The same padding technique at each convolution layer ensures consistent spatial resolution through out the reconstruction. The feature maps obtained from the individual multi-scale branch of the model are concatenated to generate a final 756 (3×256) feature map. A cloud-free 13 band Sentinel-2 image is reconstructed from this final feature map using a 3×3 2D convolution with 13 filters. The model is trained to minimize the cloud-constrained loss function L_{ccl}. Fig. 2 depict the detailed architecture of the proposed model.

III. Results and Discussions

A. Experimental Setup and Evaluation parameters

All experiments and model training are carried out in NVIDIA DGX A100 GPU SERVER consisting of eight A100 GPUs with a total of 320GB memory. The proposed model is tested on a large-scale all-season all-region multi-model uni-temporal dataset SEN12MS-CR [36]. The saturated values may happen due to clouds as well as highly elective objects. In the experiment they are treated as equals and the Sentinel-2 data is restricted to a range [0,10000] that avoids saturated values,

whereas the Sentinel-1 undergo a value clipping in the range [-25.0, -32.5] to avoid invariant pixels and noise anomalies. . The dataset is split in the ratio of 70:15:15 to generate the train test validation sets. The training triplets undergo data normalisation to the range of [0,1] before passing to the proposed deep fusion model and thereby reducing computational complexity. Data augmentation and shuffling were performed to mitigate any bias prospect and improve generalizability. The spatial resolution of the input patches is set to 256×256, that is, $M = N = 256$. The multi-scale model operates at different branch window sizes and is set to $W_1 = 11 \times 11$, $W_2 = 9 \times 9$, and $W_3 = 7 \times 7$. The model performs dilated convolutions with dilation rate d chosen from the set $1, 2, 4, 8, 16$, where $d = 1$ indicates regular convolution. The hyperparameters, such as batch size and learning rate, are fixed to 16 and $7e-6$.The quantitative evaluation of predicted cloud-free images uses various Pixel-wise and spectral-structural closeness metrics [37].

B. Result Analysis

The proposed MSDF framework is compared against four different state-of-the-art data fusion-based cloud removal techniques, including c-GAN, Simulation-Fusion GAN, DSen2-CR, and GLF-CR. Fig.3 visualizes the cloud-constrained loss obtained during the training and validation phase of the proposed model. The validation loss shows how well the model fits new data, whereas the training loss shows how well it fits training data. It is evident that there is little variation between the validation and training curves, and as a result, the model is reliable and generalizable.The loss curve The validation accuracy spiked over the training accuracy during the initial stages of training. However, as the training progressed, it was observed that the validation loss reduced and settled in a steady state with training accuracy. At epoch 198, the model exhibited a validation loss lower than the training loss. The training is stopped at this point resulting in an optimal model. The model comparison of various evaluation parameters such as MAE (Mean Absolute Error), RMSE (Root Mean Squared Error), PSNR (Peak Signal-to-Noise Ratio), SAM (Spectral Angle Mapper) and SSIM (Structural Similarity Index) for state-of-the-art techniques against the proposed method are tabulated in Table I.

TABLE I: Comparison of evaluation parameters of proposed MSDF-Net against state-of-the-art

Methods	MAE	MSE	PSNR	RMSE	SAM(°)	SSIM
c-GAN	**0.0441**	0.1074	25.29	0.3278	14.43	0.7594
Simulation Fusion GAN	0.0455	0.0886	24.55	0.2978	15.59	0.6947
DSen2-CR	0.0841	0.0182	28.70	0.1352	8.04	0.8750
GLF-CR	0.0821	0.0219	29.07	0.1481	7.64	0.8855
MSDF-Net (d=4)	0.0778	**0.0163**	**32.15**	**0.1280**	**4.42**	**0.9205**

The proposed model with a dilation rate of 4 surpassed all the state-of-the-art techniques under comparison. As per the results, c-GAN scored a minimal value for MAE but

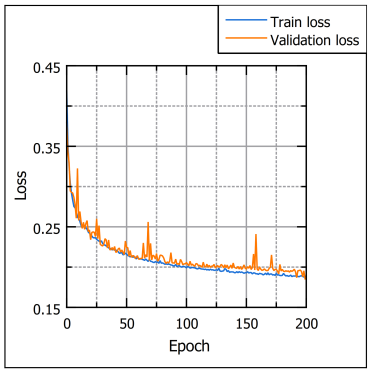

Fig. 3: Characteristic training and validation loss curve for the proposed MSDF-Net

failed to achieve credible scores for other evaluation metrics. Compared with c-GAN, all other state-of-the-art techniques exhibit superior performance except for MAE. GAN models demonstrated their capacity to reconstruct with simulated data, while real-world observations with unpredictable clouds and noise presented difficulties for GAN-based reconstruction. The proposed cloud removal framework demonstrate a lower MAE score than the recently released DSEN2-CR and GLF-CR models. The DSen2-CR model employed residual connection to achieve a better reconstruction in terms of PSNR, SAM, and SSIM. However, the residual connections increased the number of learnable parameters and failed to extract multi-scale features. The GLF-CR model employed separate global and local feature extraction networks, outperforming DSen2-CR in terms of PSNR, SAM and SSIM but scoring higher MSE value. Implementing dilated convolution in the proposed model extracts more global features without a notable increase in the number of learnable parameters. The multi-scale feature extraction procedure incorporates global and local features in a single network structure. Hence the proposed model outperformed all the state-of-the-art techniques by scoring higher PSNR, SSIM and lower SAM. Fig. 4 and 5 show the subjective evaluations of the proposed model against state-of-the-art techniques for different regions under different cloud conditions. The subjective evaluation of the results in Fig. 4 and Fig. 5 indicates that the model works for thin and thick cloud scenarios and maintains the scene's physical, texture, and colour details.

1) Effect of SAR Auxiliary Information in Reconstruction: The proposed model is trained in two settings, one fusing actual cloudy with SAR auxiliary information and the other without auxiliary information. This ablation study shed light on understanding the need and effect of SAR in cloud-free reconstruction. Fig. 6 illustrates the effect of SAR data in reconstructing cloudy images taken over diverse land regions . The penetration power of SAR through clouds aids in extracting physical information, including boundaries, textures and patterns and helps in better reconstruction. A quantitative comparison of various evaluation parameters with and without

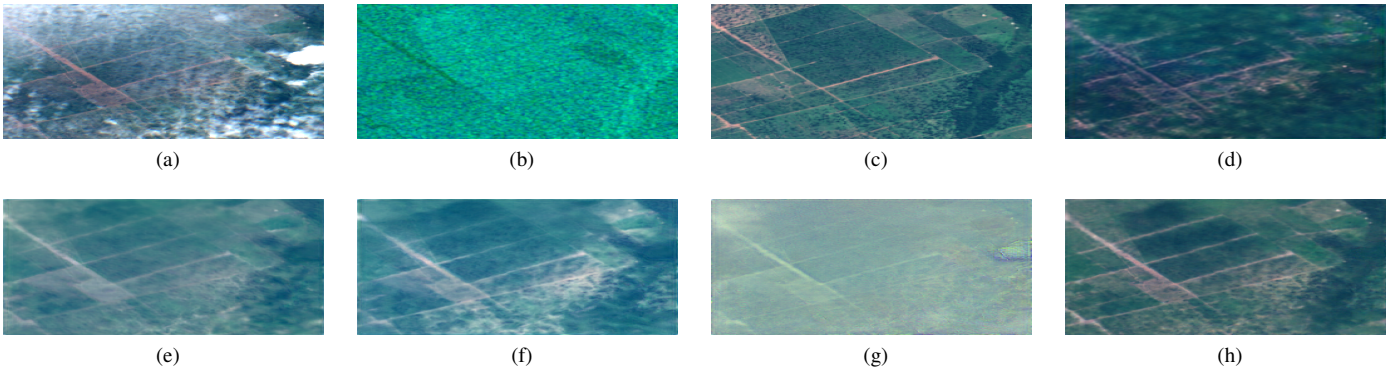

Fig. 4: Subjective comparison of proposed model with state-of-the-art techniques for an agricultural area under thin cloud, (a) cloudy input, (b) SAR auxiliary data, (c) cloud free observation, (d-g) reconstructed output for c-GAN, Simulation Fusion-GAN, DSen2-CR, GLF-CR, (h) cloud free reconstruction from proposed MSDF-Net

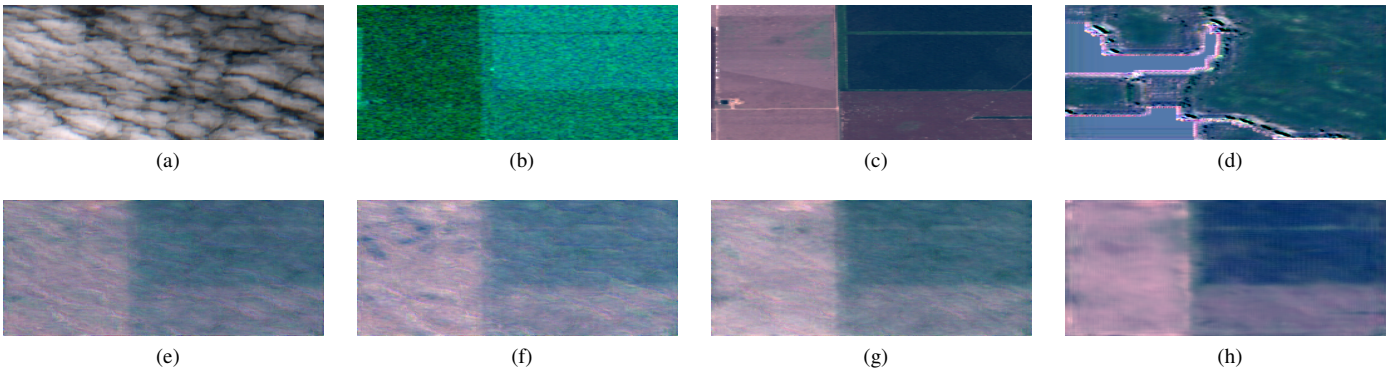

Fig. 5: Subjective comparison of proposed model with state-of-the-art techniques for for an area under thick cloud (a) cloudy input, (b) SAR auxiliary data, (c) cloud free observation, (d-g) reconstructed output for c-GAN, Simulation Fusion-GAN, DSen2-CR, GLF-CR, (h) cloud free reconstruction from proposed MSDF-Net

TABLE II: Comparison of evaluation parameters for proposed MSDF-Net with and without auxiliary data

Model Setting	MAE	MSE	PSNR	RMSE	SAM (°)	SSIM
Without SAR	0.1011	0.0269	30.03	0.1643	7.65	0.8864
With SAR	**0.0778**	**0.0163**	**32.15**	**0.1280**	**4.42**	0.9205

SAR supplementary information is given in Table II. While comparing the values in table, it is clear that reconstruction using proposed deep fusion network without SAR is poor and exhibits high MAE. The higher value of SAM and lower SSIM indicate the minimal spectral similarity compared to the model with auxiliary data. The subjective evaluation of Fig. 6 for various cloud conditions also supports the same.

2) Selection of Dilation Factor: Selecting a proper dilation factor is essential, and there is no guarantee that higher dilation rates can achieve better reconstruction. A higher dilation rate may fail to collect local characteristics by giving more importance to global features. A lower dilation rate, however, succeeds in extracting local neighbourhood characteristics but fails to do so for global features. Hence an empirical evaluation and selection of the correct dilation factor is mandatory. The proposed model is tested under various dilation rates ($d = 1, 2, 4, 8, 16$) and chosen $d = 4$ by analysing evaluation parameters. As the dilation rate further increased from 4, the performance started degrading. Table III tabulates the effect of different dilation rates on evaluation parameters.

TABLE III: Comparison of evaluation parameters for various dilation rate in proposed MSDF-Net

Dilation Setting	MAE	MSE	PSNR	RMSE	SAM(°)	SSIM
d=1	0.0779	0.0185	31.6	0.1362	4.57	0.9175
d=2	0.0823	0.0178	31.79	0.1337	4.54	0.9182
d=4	**0.0778**	**0.0163**	**32.15**	**0.1280**	**4.42**	**0.9205**
d=8	0.0804	0.0171	31.96	0.1309	4.52	0.9172
d=16	0.091	0.0213	31.02	0.1460	5.04	0.9083

IV. Conclusions

The presence of clouds in the atmosphere shrinks satellite observation quality and impacts numerous ground applications. This research article introduced a reliable multi-scale fusion framework with dilated convolution for cloud removal from

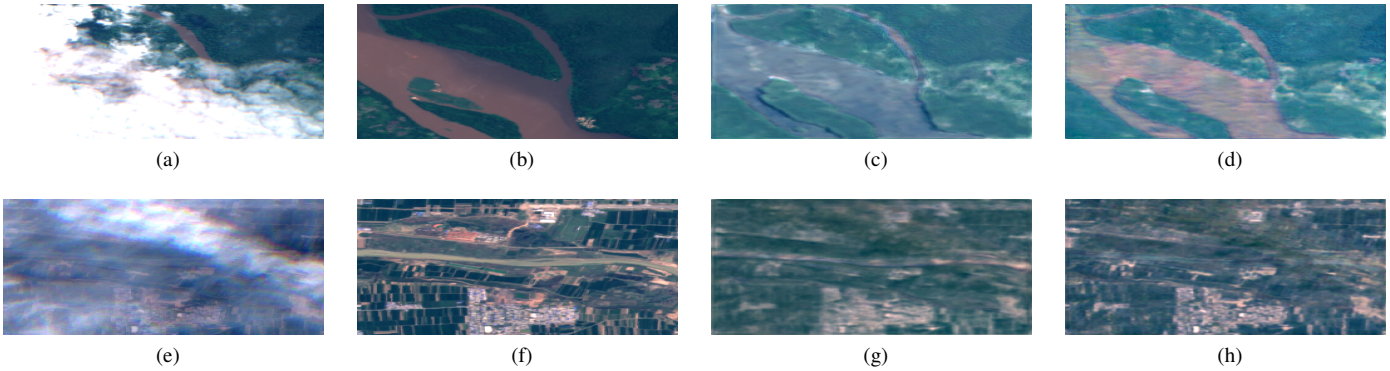

Fig. 6: Subjective comparison of proposed model with and without SAR auxiliary data for different cloud conditions (a,e) cloudy input, (b,f) cloud free observation, (c,g) reconstruction without SAR, (d,h) reconstruction with SAR

Sentinel-2 data. The model fused SAR auxiliary data with optical observations to extract underlying geophysical features. The multi-scale dilated convolutions and the cloud-constrained loss function derived from the novel cloud mask enabled global feature extraction. The quantitative study against various state-of-the-art techniques reveals superior model performance. The subjective analysis revealed the model's potential in reconstructing cloud-free data retaining colour, texture and geometrical fidelity. Also, the model excelled in handling all kinds of thick and thin clouds. This research concretes the need and effect of multi-sensor fusion for cloud removal tasks.

***Abstract*—Human inspection of aerial-based scenarios is a time-consuming, labor-intensive, and error-prone task. However, current aerial-vision-based object detection techniques have not adequately improved the detection performance of persons with sparse and weak features. In this article, a novel approach is proposed to automatically detect persons in aerial images. Specifically, numerous and multiscale instances are first implanted on fresh background images with a copy-paste mechanism to collect rich training data. Then, cropping high-resolution images into irregular sizes with density maps in the training stage. Lastly, hyper-inferencing on the raw and sliced blocks of the image by merging these overlap results to find persons. Experiments were run on the original Heridal datasets against eight approaches of popular object detectors. The metrics of precision, AP^{test}@0.5, and AP^{test}@0.5:0.95 achieved 0.9277 (+2.77%), 0.8012, and 0.547, respectively. Meanwhile, our proposed method is being evaluated on the modified Heridal and a number of publicly available datasets to make a more robust person detector in aerial images.**

I. Introduction

Object detection is a critical research problem in the field of remote sensing and has become a research hotspot. With the remarkable advances in unmanned aerial vehicles (UAVs) and computer performance, UAVs acquire vast amounts of aerial images carrying detailed geographic and graphical information. Such information has significant practical applications in military operations, civilian search and rescue initiatives, monitoring, and inspection[1]. However, high-resolution images present numerous challenges, including difficulties in identifying persons from the background, large-scale backgrounds with various object categories, and limited memory available for training networks. While person detection in fixed indoor or confined monitoring locations has improved significantly and achieved relatively good results, aerial person detection[2], [3], [4] for tiny clues about the missing person's location remains a challenge, currently relying mainly on manual and error-prone human efforts.

Data augmentation is a promising approach to address a few unbalanced samples in single scenes. It generates more representations from the original data, which improves the quantity and quality of the original data without significantly increasing data volume. Copy-paste is a robust data augmentation method that has recently received increased attention[5]. It copies an object from its original location to a new location and uses random transformations to ensure that the pasted objects do not overlap with any existing objects. However, [6] argued that it only copies the pixels that correspond to an object, not all pixels within the object's bounding box. This method places the copied instance randomly without modeling the surrounding visual context. These methods are based on the MS-COCO dataset, and their effectiveness with aerial images remains uncertain.

Many researchers have proposed solutions to address the challenges of dense small objects with uneven distribution in drone-based scenarios. For instance, [7], [8] chunks the original image into overlapping slices for detection and fuses detection results using non-maximum suppression (NMS). However, this method inevitably reduces computational speed. [9] and [10] integrate clustering and density estimation into the image cropping module, which reduces the number of image partitions but hinders portability and deployment. [11] efficiently detects smaller objects without requiring retraining the model or a larger GPU memory allocation. It chunks the images for detection and combines all inferred images into a large graph by NMS, which is time-consuming and suffers from boundary errors in detection.

This article proposes an aerial person detection scheme based on YOLOv5[12] to address the limited training samples, low accuracy, and time-consuming inference. Extensive experiments demonstrate that our algorithm achieves high accuracy and robustness.

In summary, this work has the following contributions:

- The Copy-Paste Mechanism for Object Implantation involves implanting objects from a patches library and the Heridal dataset's background. This method calculates the IoU match in detected pseudo-labels of instances, manually generates object masks, and performs multiple copy-paste to increase the number of tiny persons accurately.
- Non-uniform image cropping involves finding highly concentrated blocks of the original image with instances. Guided by density maps, this method displays the location and density of targets in a given area to create better image blocks for the next stage of object detection.

This research is funded by the National Natural Science Foundation of China (No. 62271409, No.62171381, and No. 62262067), and Scientific Research Program Funded by Shaanxi Provincial Education Department (Program No.23JK0738); Crresponding author: Yan Feng.

979-8-3503-0067-3/23/$31.00 ©2023 IEEE

- The YOLOv5 C3 module has been improved to C3TR to account for tiny persons. The loss function of YOLOv5 has been altered, with different weights assigned to the real labels and pseudo-labels.
- Multiple experiments have been conducted on synthetic datasets created based on the optimized Heridal dataset. The proposed method's detection results have also been compared with state-of-the-art methods using publicly available datasets.

This article is organized as follows: Section 2 provides a review of related works and our improvement tips. Section 3 presents our methodology and the experiments conducted with the Heridal dataset in detail. Section 4 reports on the experimental results and analysis. The conclusion is presented in Section 5.

II. RELATE WORKS

A. Anchor-Based Detector

In this work, the proposed method was conducted based on the YOLOv5 framework and gradually was optimized by modular networks of YOLOv5 to improve detection accuracy. The YOLOv5 framework consists of four main components: data preprocessing at the input, feature extraction network for the Backbone, feature enhancement network at the Neck, and the detection head. The feature extraction network comprises CSPDarknet53, which includes Conv modules and C3 modules (our experimental tests show that the C3TR module performs better on the Heridal dataset). A feature enhancement network is added between the feature extraction network and detection head to mine the semantic information within the image better and make it more applicable for classification. The YOLOv5 framework utilizes SPP or SPPF network structure to convert feature maps of arbitrary sizes into fixed-size feature vectors and employs the PANet network structure, which has a top-down bidirectional feature fusion backbone. For predicting the bounding box, the detection head network adopts the YOLOv3 Head structure and assigns three anchors to points on each layer of the image.

B. Improved Loss Function

The YOLOv5 loss function includes three parts: Bounding Box regression loss, object confidence loss, and category loss. Every network separates the feature map into cells that output a vector of [t_x, t_y, t_w, t_h, p_o, c_1, c_2, ...]. t_x and t_y represent the centroid's offset between the prediction box and the corresponding anchor box, while t_w and t_h are employed in computing the box width and height. p_o expresses the chance that the cell (prediction box) contains the object, and c_1, c_2, ..., are the predictions' values for the corresponding categories. All three loss parts are calculated by linking to positive sample pairs, and each output feature map is summed up straight to obtain the final loss of each part. Each network's feature map cells are autonomous of each other.

$$\mathcal{L}_{v,5}\left(\mathbf{t}_p, \mathbf{t}_{gt}\right) = \sum_{k=0}^{K} \left[\begin{array}{l} \alpha_k^{balance} \alpha_{box} \sum_{i=0}^{S^2} \sum_{j=0}^{B} \mathbb{I}_{kij}^{obj} \mathcal{L}_{\text{CloU}} \\ +\alpha_{obj} \sum_{i=0}^{S^2} \sum_{j=0}^{B} \mathbb{I}_{kij}^{obj} \mathcal{L}_{\text{obj}} \\ +\alpha_{cls} \sum_{i=0}^{s^2} \sum_{j=0}^{B} \mathbb{I}_{kij}^{\text{obj}} \mathcal{L}_{cls} \end{array} \right] \quad (1)$$

Where K, S^2, and B in Eq. (1) are the output feature maps, cells, and a number of anchors on each cell, respectively. α_* (α_{box}, α_{obj}, α_{cls}) is the corresponding item's weight, and the default values in hyp.scratch-high.yaml is (α_{box} = 0.05, α_{obj} = 0.3, α_{cls} = 0.7), $\mathbb{I}_{kij}^{obj}$ indicating whether the k output feature map, i cell, and j anchor box are positive samples, with 1 indicating positive and 0 indicating negative. t_p, t_{gt} is the prediction and ground-truth vector; it is used to balance the weights of the output feature maps for each scale, and the default values are [4.0, 1.0, 0.4], which size of feature maps correspond to 80×80, 40×40, and 20×20, respectively.

$$\begin{aligned} \mathcal{L}_{v5}^{\text{total}}\left(\mathbf{t}_p, \mathbf{t}_{gt}\right) = & \beta_{\text{truth}} \mathcal{L}_{v5}^{\text{truth}}\left(\mathbf{t}_p, \mathbf{t}_{gt}\right) + \\ & \beta_{\text{pseudo}} \mathcal{L}_{v5}^{\text{pseudo}}\left(\mathbf{t}_p, \mathbf{t}_{gt}\right) \end{aligned} \quad (2)$$

The total loss is defined as Eq. (2), where weights β_{truth} and β_{pesudo} are used to adjust the number of unreliable pseudo-labels, $\mathcal{L}_{v5}^{\text{truth}}$ and $\mathcal{L}_{v5}^{\text{pseudo}}$ are the same as in Eq. (1).

III. OUR PROPOSED METHOD

Since the Heridal dataset includes only a few instances, direct training from scratch results in slow network convergence and inferior detection performance. Thus, the primary experimental strategy for the YOLOv5 pre-trained model involves fine-tuning the training model on the Heridal dataset.

A. General Framework

As shown in Fig. 1, our method employs different strategies to optimize the algorithms in the training and inference phases. It consists of five main parts: object implantation (green dashed box), image cropping (yellow dashed box), hyperparameter evolution (brown dashed box), slice-assisted detection (purple dashed box), and one-stage detector (blue dashed box). The object implantation module generates pseudo-labels between the Heridal background images and object libraries. The image cropping module is then used to crop blocks of images containing dense regions of persons and add them to the training subset using non-uniform slicing. The detector combines the detection results from cropped and original images using NMS. Moreover, optimizing the pre-trained hyperparameters using a genetic algorithm on the Heridal dataset in the preprocessing stage can significantly improve model training convergence speed and accuracy.

B. Object Implantation with Copy-Paste Augmentation

In Search and Rescue (SaR) scenarios, persons captured by drones often appear in non-urban and remote areas, leading to a scarcity of available real-world samples. The object implantation algorithm aims to increase the number of labeled training samples by generating pseudo-labels in unlabeled images to enhance the predictive performance of the detection

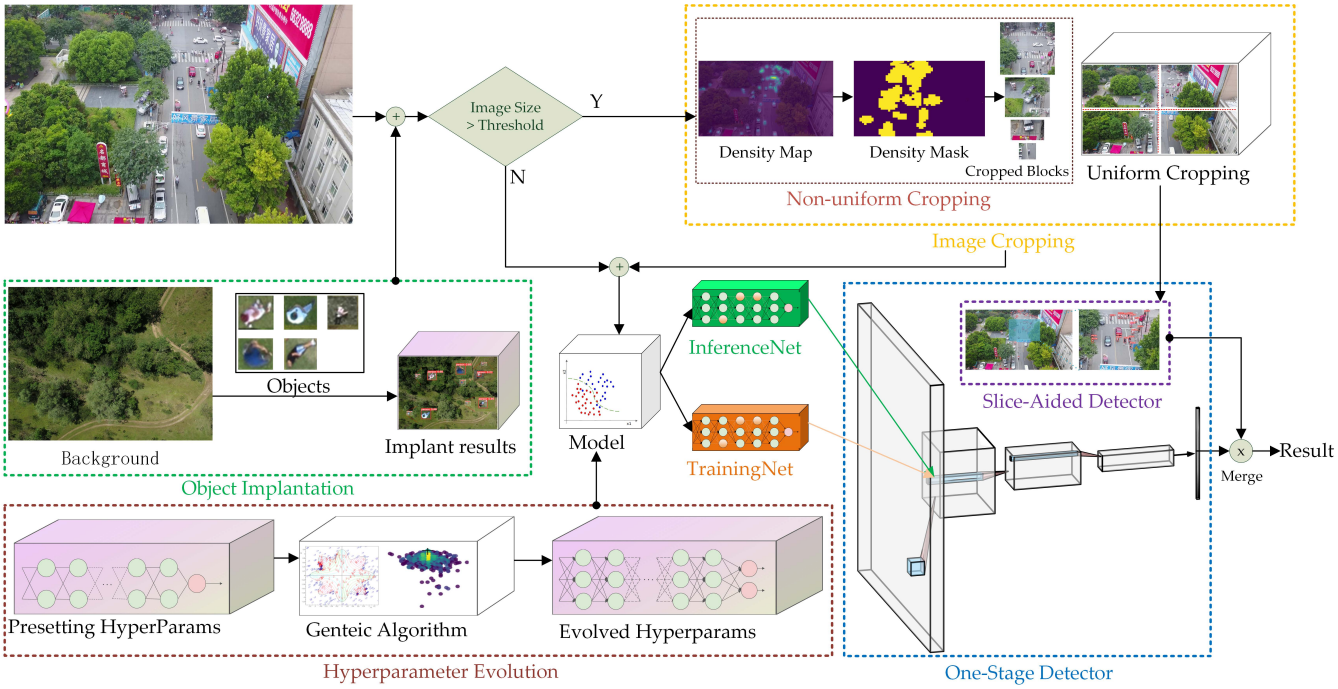

Fig. 1. General framework of our proposed scheme. The main modules have been drawn with different dashed boxes.

model[13]. In this study, a high-confidence detection model is employed to infer unlabeled images and derive pseudo-labels. The detector first infers under the pre-trained model to obtain predicted samples with high confidence, followed by an IoU matching calculation between predicted and real labels. The mask generator then extracts the mask of the pseudo-labels to create an object instance library. Lastly, pseudo-instances are formed by randomly combining objects and backgrounds. The trainer utilizes both real and fake samples to optimize the model's parameters and obtain the best performance.

C. Image Cropping Guided by Density Map

The cropping strategy can potentially increase the training samples; however, random or mosaic cropping cannot guarantee that the cropped region contains valid data, resulting in an imbalance between negative-to-positive sample ratios. As illustrated in Fig. 2, our experiments with high-resolution aerial images (obtained from the VisDrone2019[14] Val subset) used a density estimation network to crop images into non-overlapping blocks before mapping the training labels regression into the cropped blocks. A dense multi-cropping object detector network based on YOLOv5[12] was proposed, which utilizes Density Map Guided Object Detection network ((DMNet)[10] and the Twice Observed Network (YOLT) [7]) to enhance detection accuracy.

The non-uniform cropping strategy employs density maps that generate object-specific densities using MCNN[15] and class-wise-kernel masks. Initially, pixels with a density mask value of 1 are selected, and they are subsequently connected into a large candidate region using an eight-linked region. Finally, the candidate region's outer rectangle is used to crop the original image, but regions with lower resolution than the density value are removed. As illustrated in Fig.2, the DMNet processes the original image to create cropped boxes with numerous positive samples.

D. Slice-assisted Detection

Various factors such as altitude can impact the detection algorithm in UAV-captured images, leading to reduced efficiency in search and rescue operations. To address this, the following approach was proposed:

- Identify the shortest flight pathway to the object centroid by inferring it once on the original map.
- Lower flight altitude or adjust the lens to capture close-range images of the pathway for improved detection accuracy.
- Merge detection results for the region.

To create a dataset of sliced samples, images are sliced to a fixed size using sliding windows with overlap. The Heridal dataset contains few person samples and many background samples following the slicing process. To address this, samples with boundary values during the slicing process are removed. The trainer settings are kept consistent with the original image, but the input size is based on the size of the slices. As demonstrated in Fig. 3, the detection results are combined from both the original and zoomed-in cropped image using the NMS method to obtain the final results.

IV. EXPERIMENTAL RESULTS ANS ANALYSIS

All experimental results in this study were conducted on the NVIDIA Tesla V100 * 2 hardware platforms with 16G×2 memory. YOLOv5 version 6.0 was used, along with CUDA

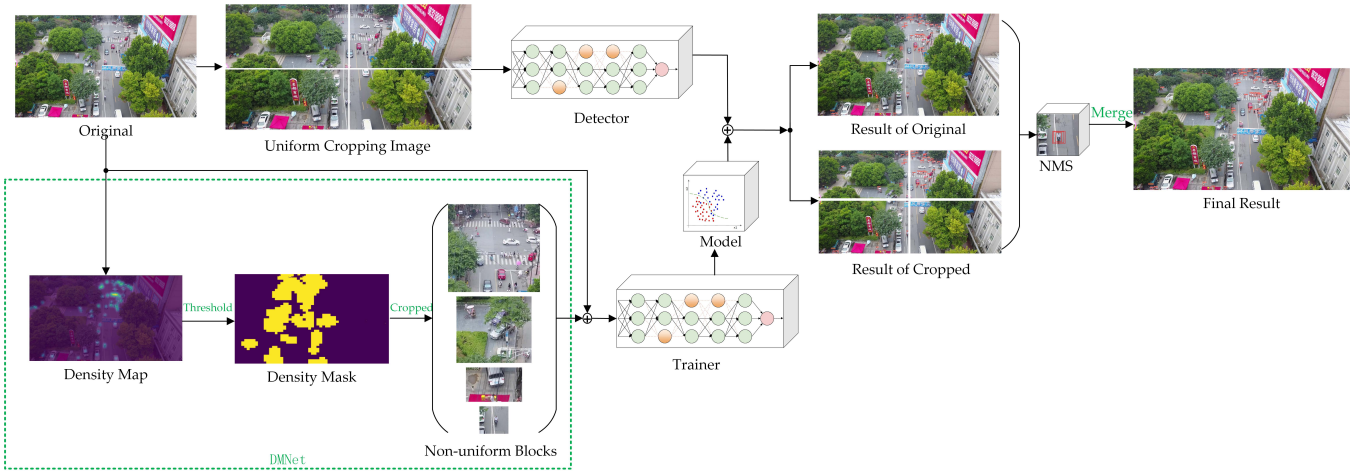

Fig. 2. Cropping of images is done in both the training and inference stages. Density map-guided non-uniform cropping is performed, while uniform cropping of slices without overlapping regions is used during inference. The detection results obtained from the original and cropped images are then combined using NMS to obtain the final detection results. The threshold is also utilized to create a density mask for the connectivity map.

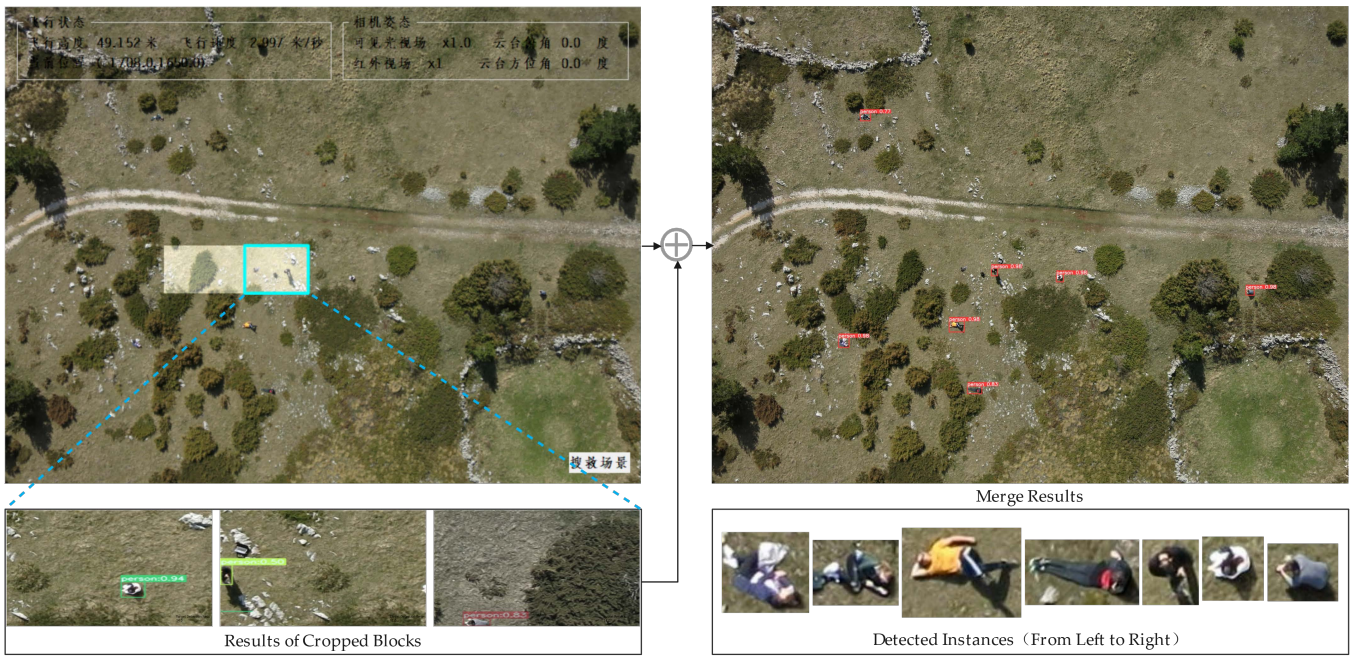

Fig. 3. Slice-assisted for fine-tuning detection results.

version 10.2, SGD as the gradient descent algorithm, and ResNet101 as the Backbone.

A. Dataset and Setting

1) Optimized Hyperparameters: The correct initialization of setting parameters is crucial for producing better final results. As the default parameters of the pre-trained model were evolved on the COCO dataset, they do not well fit SaR scenarios. YOLOv5 has 28 hyperparameters (hyps) for various training settings. To optimize these hyps, a base_hyp is selected to generate mutations based on the trained hyps, and then the previous hyps are weighted based on the results of each previous evolution. Therefore, optimizing hyperparameters is crucial for correctly preprocessing hyps before training.

2) Datasets: The Heridal dataset serves as the primary experimental data for this study. It comprises 1650 high-resolution images (4000×3000) containing instances of persons in various non-urban areas such as mountains, forests, oceans, deserts, and so on. The Department of Electronics and the Polytechnic Institute of the University of Split collected these images using unmanned helicopters. TABLE I provides an overview of the number of training subsets and test subsets. The original dataset was optimized for the experiments and primarily consisted of the following.

- Removing unlabeled background samples and error la-

bels.

- Adding samples from the Heridal Patches library randomly to the background, and the labels default to the aspect ratio of the images in the Patches.
- Cropping blocks that contain objects with uniform overlapping sliding windows of sizes 320×320, 400×400, 412×412, and 416×416.

B. Model Training and Analysis

1) Results of Cropped Heridal Dataset: The Heridal dataset initially contained numerous unlabeled background images. To address this, the object implantation method is employed to add samples from the patches' library, resulting in the Heridal_Impant_1536 dataset. All results were obtained using the YOLOv5s model with a batch_size of 32. TABLE II displays the training metrics for the Heridal, Heridal_Impant_1536, and cropped blocks size of samples: [320×320], [400×400], [412×412], and [416×416] datasets. The precision of Heridal_Impant_1536 increased from 0.8262 to 0.8876 (↑ 6.14%), while mAP@0.5 increased from 0.7452 to 0.7884 (↑ 4.32%). Among all the datasets, Heridal_Crop_416 achieved the best training metrics, with precision of 0.9724, recall of 0.9466, mAP@0.5 of 0.9799, and mAP@0.5:0.95 of 0.7729. Despite the decrease in the average inference speed on the test_set by 1.3ms, 2.9ms, and 1ms, respectively, it still meets the real-time detection requirements.

2) Results of Different Pretrained Model: In this experiment, different model depths with various batch sizes were utilized to enhance training speed, and the input size was set to 1536×1536. Fig. 4 displays the training precision, recall, mAP@0.5, and mAP@0.5:0.95 curves for the Heridal dataset on various YOLOv5 models, including s, s6, m, m6, l, l6, x, and x6. Methods 1-8 were performed on the Heridal_1536 dataset using a training strategy that adds non-uniformly cropped blocks and original images to the trainer. Methods 9-16 were performed on the Heridal_Implant_1536 dataset using object implantation. The training metrics were significantly improved on the Heridal_Implant_1536 dataset, with the best metrics being precision (0.9277), recall (0.73), mAP0.5 (0.802), and mAP0.5:0.95 (0.547). When compared to the deepest model YOLOv5x6 (method 16), the shallowest YOLOv5s model (method 8) showed a 4.01% decrease in precision, 1.68% increase in recall, 1.28% decrease in mAP0.5, and 2.65% decrease in mAP0.5:0.95, with the YOLOv5s model only having 15.8M parameters, making it more suitable for deployment on embedded devices.

C. Model Inference and Visualization

The trained model is compiled by TensorRT to create a serialization engine on embedded devices, which includes dynamic batch inference and model quantization. During training, data with different batch sizes can be iterated upon, and input tensor sizes (shapes) are uncertain during inference. Therefore, making full use of multiple batches can significantly improve the model's detection speed. Model quantization involves converting a signal's continuous values into a limited number of discrete values. In training CNNs, the data precision of FP32 is commonly used to represent weights, biases, activation values, and so on. However, previous experience has shown that low precision (FP16, INT8) sacrifices some training accuracy but reduces memory usage and shortens model training time. In this work, the quantization accuracy is set to FP16.

1) Comparative Tests: The results of the detection speed on Jetson Tx2 and Xavier NX are presented in Table III. These tests were conducted at the maximum frequency by default. With the same YOLOv5s model and batch size of 4, Xavier NX's inference speed is 19.1ms faster than the baseline, with nearly identical parameters. Although the quantized model loses about 2-3% accuracy, inference times are significantly

Table IV displays the results of our proposed and existing algorithms on the Heridal dataset. The baseline method was first proposed on the Heridal dataset, but its detection accuracy was only 34.8%, which could not meet the application requirements. In recent years, more complex networks such as Faster RCNN, RetinaNet, and SSD have significantly improved detection accuracy, but at the expense of slower detection speed. In this study, reliable training results are achieved based on YOLOv4, YOLOv5, and YOLOv6, taking into account detection accuracies and inference speeds on embedded devices. As shown in Table IV, the optimal precision was 92.77%, but the recall of the YOLO series was lower, primarily due to the IoU evaluation's unfavorable impact on small object detection, and a slight deviation of the bounding box could result in a marked deterioration of detection performance.

2) Detection Results: Fig.5(a) displays the YOLOv5s detection results on the Xavier NX, indicating that it can effectively detect persons in various jungle scenes. The detection results of the object implantation method on the Heridal_Implant_1536 val_set are shown in Fig.5(b), where synthetic samples of per-

Fig. 5. Detection results of different methods on the Heridal test_set. (a) Detection results of the No. 8 method from Table 4 or Table 5 on the Heridal test set. (b) Detection results of the object implantation method on the Heridal_Implant_1536 val_set. (c) Merge detection results of original images and cropped blocks on the Heridal test_set. To facilitate the target clarity, a small target of each different image sequence was marked and enlarged simultaneously by a red box.

sons generated using copy-paste techniques can be accurately detected. The detection results of merging the original image with sliding windows are shown in Fig.5(c). A detector with a model size of 416×416 on cropped images can compensate for the flaws found in the original images, particularly detecting persons, thereby improving the object detection accuracy.

D. Ablation Study

1) Numbers of Objects based Copy-Paste Mechanism: The positive and negative samples used in this study were obtained from the patch libraries in the Heridal dataset and patches implanted by the Copy-Paste Mechanism to the background. There were 29,050 positive and 39,700 negative instances, all of which were 81×81 pixels. Additionally, the size of synthesized positive and negative instances was set to be less than 32×32 pixels (i.e., small objects in MS-COCO). According to Table V, the number of implanted positive instances varied from 3 to 7, while the number of implanted negative instances was 0. Based on the results, the optimal combination was determined to be [positive = 5, negative = 0], with non-repeated samples and the following performance metrics: [precision = 0.8876, recall = 0.7023, APval@0.5=0.7884, APval@0.5:0.95=0.5205]. These experiments showed that increasing the number of positive instances significantly improved the accuracy of the model in high-resolution images, while adding negative samples repeatedly had little impact on model performance, possibly due to numerous negative instances or backgrounds contained in the Heridal dataset.

2) Sizes of Blocks with Non-uniformly Cropping: DMNet dynamically adjusts the number of objects to cover all regions

TABLE V
THE RELATIONSHIP BETWEEN THE NUMBER OF IMPLANTED POSITIVE OBJECTS AND THE PERFORMANCE OF DETECTION MODELS.

Num of Pos	Num of Neg	Repeat	Precision	Recall	AP^{test}@0.5	AP^{test}@0.5:0.95

TABLE VI
THE IMPACT OF NON-UNIFORM CROP BLOCK SIZES ON THE PERFORMANCE OF THE DETECTION MODEL

Threshold	Crop_Size	Train_Set	Val_Set	Precision	Recall	AP^{test}0.5
Baseline				0.8262	**0.6914**	0.7452
0.08	320x320	506	87	0.8037	0.6806	0.7356
1	320x320	472	69	0.8112	0.6842	0.7379
5	500x500	203	41	0.8496	0.6867	0.7428
10	500x500	146	29	0.8625	0.6888	0.7516
15	640x640	117	21	0.8709	0.6903	0.7598
20	640x640	97	16	**0.8721**	0.6884	**0.7603**

in the image. As the threshold is increased, the boundary becomes more irregular, and pixels on the boundary are more likely to be filtered out. Additionally, a sliding window is applied to the density map, and its size is set equal to the average size of objects in the training set, while the step size is set to the size of the sliding window (without overlap). The sample size in this study was primarily impacted by adjusting the density threshold and crop window size, as shown in Table VI, and the test results were obtained from the Heridal_Implant_1536 dataset. According to Table VI, the optimal training metrics were achieved when the density threshold was set to 20 and the cropping window size was [320×320]. A lower density threshold resulted in no connected domain and fewer usable samples to crop. Additionally, a crop block that is too small can cause severe deformation of instances when combined with the original images. Thus, selecting appropriate density thresholds and cropping window sizes can significantly impact the model's performance.

V. CONCLUSION

In this study, the Copy-Paste Mechanism for object implantation and a slice-assisted inference approach with multiscale feature fusion was proposed, which achieves better detection performance on the optimized Heridal dataset. Comparative experiments using YOLOv5 demonstrate that our algorithm achieves better average detection precision, with the best metrics being 92.77% for precision, 68.55% for recall, 80.12% for mAPtest@0.5, and 54.7% for mAPtest@0.5:0.95. Additionally, dynamic batch inference and parameter quantization were tested on the embedded devices Jetson Tx2 and Xavier NX, exhibiting promising lightweight results. In the future, our work will involve the design of better pseudo-label generators and more efficient person detectors.

***Abstract*—Infectious disease is a terrible pandemic around the world, the economy and even people's lifestyles are affected while implementing a lot of standard operating procedures (SOPs) to control the spread of the virus. One of the most effective ways is to control the physical distance between people. Therefore, a Social Distancing Monitoring (SDM) system can be used to track the safe distance between people. In this study, a comparison between algorithms will be made to identify the most efficient algorithm based on human detection results. As a result, the OpenPose algorithm has outstanding human detection results compared with YOLOv4 and YOLOv4-pedestrian. Furthermore, a distinctive bounding box method for human detection has been proposed, which is defined from the human skeleton using the OpenPose algorithm. Hence, SDM will be efficient after a perspective transformation to calculate the distance between people, since most of the people in the frames have been detected. Finally, this study will discuss how the power of AI enhances the SDM system in detecting humans and calculating the distance between people detected.**

***Index Terms*—infectious disease, human detection, social distancing monitoring, perspective transformation, calibration**

I. Introduction

Every epidemic can be controlled by two important measures: quarantine and physical distancing. Since 2003 the SARS virus began spreading worldwide, and these measures have always been part of the SOPs for ensuring public health. In 2019, the World Health Organization will promote a physical distance of at least one metre between people as infectious diseases such as COVID-19 will be transmitted through close contact and the air [1]. Thus, an SDM system can determine the distance between people to determine whether they are at a safe distance.

Technology is advancing rapidly, and Artificial Intelligence (AI) has become a part of everyone's daily lives. Hence, researchers have found that machine learning is effective in automating tasks such as automatically detecting the physical distance among people in real-time using a surveillance camera [2]. There are, however, many concerns associated with a real-time SDM system. To solve the perspective distortion, we performed a perspective transformation with cv2.getPerspectiveTransform and cv2.warpPerspective [3] from the OpenCV package, which implements homogenization [4]. For example, the perspective transformation for calculating the distance between people should proceed in real time by turning a frame into a bird's-eye view. Furthermore, a calibration process must be done to ensure the pixel measured in the frame can be converted to a centimetre measurement. From there, the distance measurement will always be converted to real distance to ensure the violation is detected correctly. Besides, the violated distance measurement, 180cm, will always be consistent, even if the videos are captured from different angles. Therefore, this study adopts YOLOv4-pedestrian, YOLOv4 and OpenPose models to find suitable and effective human detection algorithms.

This paper provided new insights into the studies about some algorithms used for human detection, which focus on rendering bounding boxes for each human detected. In addition, distance calculation using Euclidean Distance [5] after perspective transformation to avoid the distortion issue of the video captured, as well as the calibration process to ensure the distance measurement in the real world.

The paper first briefly overviews the recent history of SDM and introduces the algorithm used for human detection and distance measurement. After that, Section 2 discusses literature reviews on the algorithms proposed and the main contributions of the related SDM papers. Furthermore, Section 3 will discuss the process to execute the SDM system, and the results of the system will be proposed in Section 4. Last but not least, the summary of the experiment and future works will be presented in Section 5.

II. Literature Reviews

Many pieces of research discuss various deep learning algorithms to detect people and several methods of calculating the physical distance between people in real time. Some experiments achieved high accuracy while detecting people using the YOLO algorithm. For example, Ahmed et al. proposed a framework of the YOLOv3 algorithm to perform

979-8-3503-0067-3/23/$31.00 ©2023 IEEE

deep learning-based SDM without any occlusion, as they used overhead perspective video as input data [6]. With the transfer learning of an overhead human dataset with a pre-trained YOLOv3 algorithm, the accuracy of the detection model increased by 3%, which is 95%. Using the Euclidean distance method, the distance among people can be calculated by the centroid of the bounding boxes detected. On the other side, Ahmed et al. also proposed the pre-trained Faster Recurrent Convolutional Neural Network (RCNN) model with the same method and achieved an accuracy of 96% [7].

With a similar approach, Rezaei and Azarmi conducted people detection in indoor and outdoor environments by using large datasets, including MSCOCO and Google Open Image (GOI) datasets, to train and test the YOLOv4-based Deep Neural Network (DNN) model [8]. They used a bird's eye view to calculate the distance for calibration purposes so that the high-risk zone of infectious disease would be identified. Furthermore, Shao et al. trained YOLOv3 with the Merge-Head dataset, which was a larger dataset, and fine-tuned it with a smaller dataset called the UAV-Head dataset sourced from UAV-Head to save resources as it is a similar view of surveillance video [9]. Training results achieved an average precision of 92.22% and 88.5% for testing with the UAV-Head dataset. This experiment only detected the human head and applied a perspective transformation to ignore a complex background.

In another study conducted by Punn et al., they detected humans using the YOLOv3 algorithm while fine-tuning Deepsort techniques to assign ID for detecting people and achieved a balanced mean Average Precision (mAP) and training time with the highest score on FPS [10]. However, they had mentioned their distance measured using the L2 norm but did not illustrate clearly the distance measurement process. In addition, Qin and Xu also used Euclidean distance to calculate the distance between people. They trained the SSD 300 model using the VOC2007 dataset to identify the human object [11]. To measure the distance between two humans, the top-left point of the bounding boxes would be used.

From the experiment of Ansari and Singh [12], a CNN-based human detection has been proposed. Two CNN models have been compared: one of the models, Model 1, consists of two convolutional layers with two pooling layers, while another model, Model 2, consists of three convolutional layers with three pooling layers. Ultimately, Model 2 performs better than Model 1. As one of the methods for detecting humans using the skeleton, Al-Sa'd et al. used OpenPose on the EPFL-MPV, EPFL-Wildtrack, and OxTown public datasets and achieved an accuracy of 94.9%, 99.7% and 95.6% respectively [13]. A perspective transformation was also been carried out to evaluate the crowd density map and social distancing monitoring, which is useful for avoiding occlusion and dealing with missing values.

III. Proposed Method

According to most experiments, the YOLO model had a good result in detecting humans, as it achieved an average accuracy. Therefore, we proposed to utilise the YOLOv4-pedestrian model [14] to compare with other algorithms such as YOLOv4 and OpenPose [15] for human detection. After comparison, we used the OpenPose algorithm to test distance calculation using different points. Fig. 1 showed the entire process flow of our proposed method. At first, the OpenPose algorithm will perform the human feature extraction to an input video, and each human detected was covered by bounding boxes. To calculate the distance precisely, the video frames' perspective was transformed into a bird's eye view to avoid distortion. After calculating the distance between people, the people were classified into three different risk levels in different colours, as shown in Eq. (1).

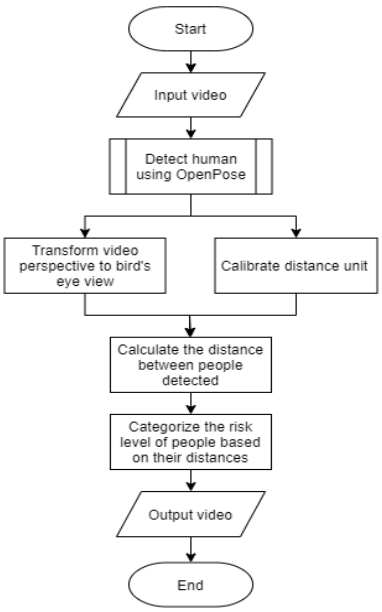

Fig. 1: Our proposed process flow

$$\alpha = \begin{cases} \text{safe}, & \text{if } \delta > 230. \\ \text{careful}, & \text{if } 180 < \delta \leq 230. \\ \text{danger}, & \text{otherwise.} \end{cases} \quad (1)$$

where α is represented as the risk level of certain people and δ refers to distance between people.

A. Human Detection

OpenPose algorithm detected the skeleton of 25 human parts from head to foot. Thus, we integrated the detection mechanism, bounding box, as utilised by the YOLOv4-pedestrian model and YOLOv4 model detections as shown in Fig. 2.

To render a bounding box, the x and y minimum values of the human skeleton detected by OpenPose have been assigned as the bounding box's top-left coordinates. The width and height of the bounding box are calculated by taking the maximum value minus the minimum value of the same detected human skeleton.

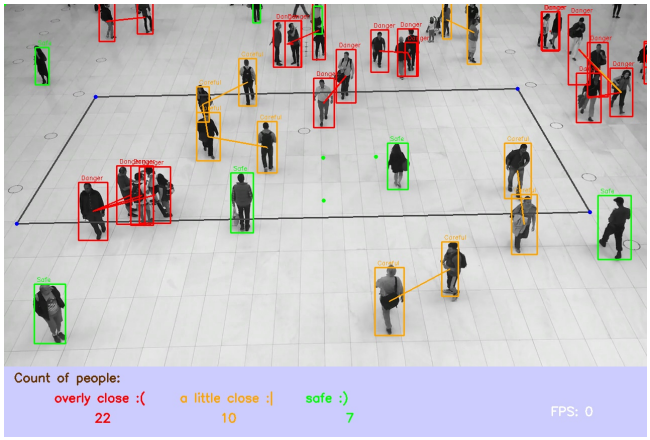

Fig. 2: Output of OpenPose detection.

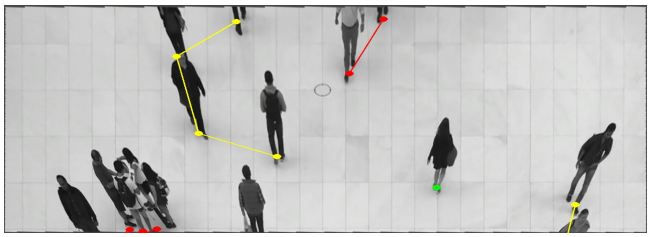

Fig. 3: Detection output in top view perspective.

B. Distance Monitoring

To improve the detection results of human detection in social distance measurement, we performed a perspective transformation process before distance measurement. There are seven points that require manual definition: the first four points (blue dots) will be used in perspective transformation, and the next three points (green dots) for calibration are shown in Fig. 2. These three dots formed two orthogonal lines, and each line represented a length of 180cm in the real world. By doing this, the distance between people can be accurately calculated when the frames have been turned to a top-down perspective, as shown in Fig. 3. Besides that, the distance calculated by pixel in frames is mapped and calibrated to the distance in centimetre measurements by using the two orthogonal lines.

There were three categories of risk level, which represented whether the person had a higher chance of getting infected by a disease with a relatively short social distance between each other. To ease the identification of one's risk level, each detected person was rendered with a bounding box in different colours. Based on Eq. (1), the bounding box in red represented the risk level, α equal to danger, and it turned to orange when the risk level was a careful status, while the green box indicated people in a safe distance from others. If the count of the red bounding box is high in a certain area, the chance of people around that area getting infected may possibly be higher.

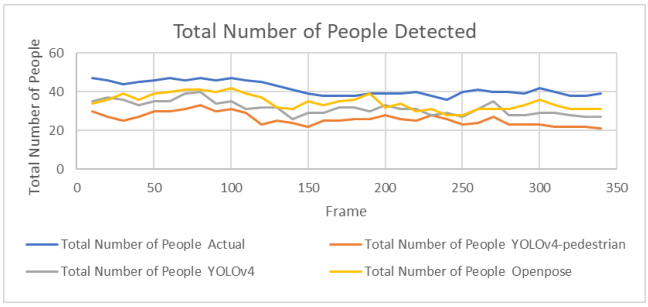

Fig. 4: Comparison among algorithms used in detecting total number of people.

IV. Results

We performed a quantitative metric based on the number of humans detected to evaluate the system's performance. A comparative approach was adopted to evaluate the accuracy of detecting humans. The advantage of using this approach is identifying the efficient algorithm used for the current video or situation.

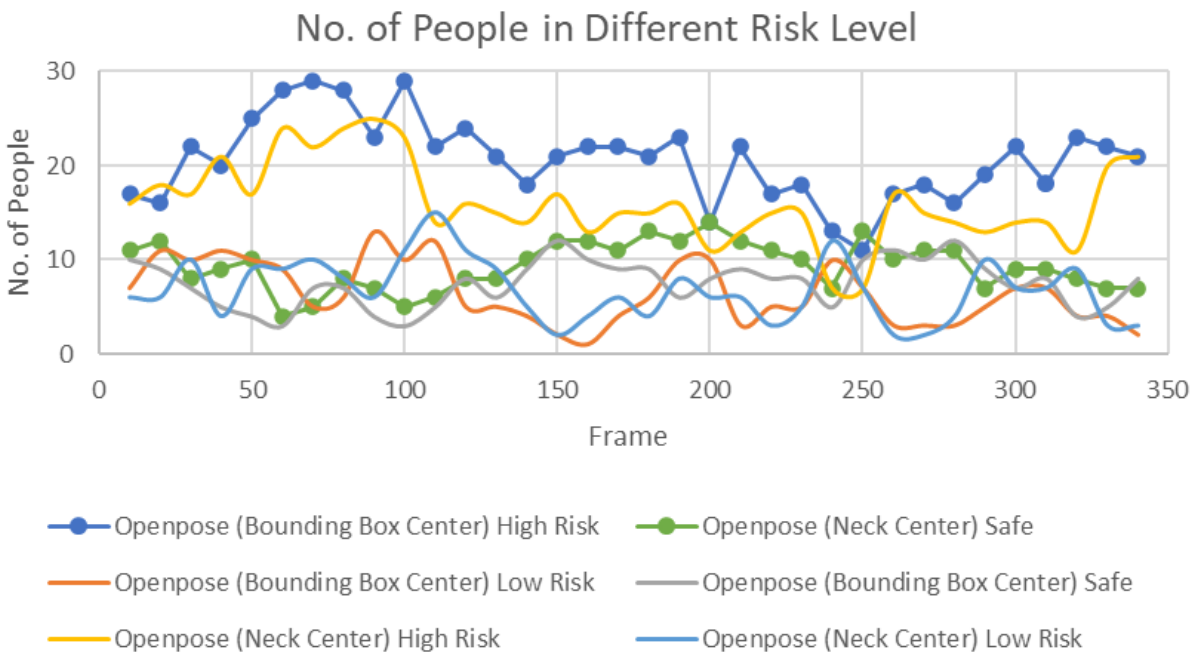
A. Total Number of People Detected

A comparison chart for the detection results among three detection algorithm categories is shown in Fig. 4. In the figure's legend, the Actual (blue line) referred to the number of people counted by using naked eyes (ground truth), and others were utilising different approaches to the human detection results. In this study, the input video did not contain any occlusions or obstacles, so most of the human activity has been clearly detected. By looking at the yellow line in the chart in Fig. 4, the OpenPose detection result was the most accurate, as most of the detection results were close to the actual count of people detected.

B. OpenPose Detection Results

To find a suitable centre point for distance calculation between people, this experiment used two types of centre points after human detection using OpenPose: the bounding box's bottom centre point and the neck part of the skeleton as centre point. Thus, Fig. 5 compared the number of people detected using OpenPose at the different centre points and categorised them by risk level. In the end, OpenPose detection using the bounding box's bottom centre point detected most people in the violated distance, while OpenPose using the neck part of the skeleton as the centre point detected many people in the safe distance.

Based on Fig. 6, the shape of the human detected was stretched after a perspective transformation. Thus, the neck centre as in Fig. 6(a) might not be an accurate centre point for calculating the distance between people. Furthermore, at the beginning of the system, the last three points selected by users indicated that a horizontal calibration of 180 cm was the equivalent of three boxes of floor tiles, while a vertical calibration of 180 cm was one and a half boxes of floor tiles. Hence, Fig. 6(b) which was the OpenPose detection using



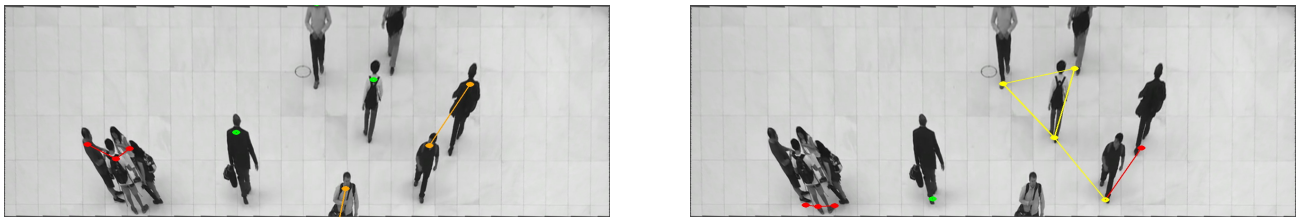


Fig. 5: OpenPose detection results in various risk levels.

(a) Neck centre point

(b) Bottom centre point

Fig. 6: Bird's eye view: OpenPose detection in different centre points.

the bounding box's bottom centre point, had a more accurate distance calculation between people based on the calibrations.

V. Conclusion

In this study, the SDM system was able to calculate the distance between people after a perspective transformation and then categorise people into three risk levels. For human detection, the state-of-the-art algorithm was YOLOv4-pedestrian, which is a pre-trained YOLOv4 model that only detects pedestrians. This study compared the detection results of YOLOv4-pedestrian with two pre-trained algorithms, YOLOv4 and OpenPose. Nonetheless, OpenPose can produce a good human detection result as the video did not contain any occlusion. Hence, this suggests that future research should be undertaken to improve the performance of the system to test the videos in different conditions. For example, videos which contain stairs, objects occluding or in dark conditions, may affect the results of human detection and also cause the distance measurement to be defective.

This system achieved the objectives mentioned in the introduction. At first, a perspective transformation was applied to the video to transform the video's perspective to a bird's eye view, as the distance between people can be calculated accurately. Moreover, the centimetre unit is used for distance measurement, as pixels are calibrated into centimetres by using the last three points selected at the beginning of the system. An improvement in future, the four points of perspective transformation can be selected automatically instead of pointed manually. Furthermore, this paper served as fundamental research on this topic, which does not own a dataset. In future, the system can be tested with a dataset which contains videos with different angles of depression to test the calibration process and the reliability of the system.

Acknowledgment

We would like to express our great appreciation to Tunku Abdul Rahman University of Management and Technology (TAR UMT), under internal grant project no. UC/I/G2021-00073, for the financial and resource support needed to carry out this project.

***Abstract*—Spotting macro and micro expressions proves more demanding than subsequent tasks such as recognizing or classifying expressions. This intricate process entails pinpointing the precise commencement, conclusion, and pinnacle frames of brief facial expressions within video footage. Our study delves into the susceptibility of expression spotting to biases ingrained in deep learning models, often stemming from a lack of diversity in the training data. These biases manifest diversely, such as an overemphasis on specific expression categories, genders, or racial backgrounds, leading to subpar performance on other samples. These spurious biases in deep learning models adversely affect classification accuracy. Our work aims to unearth common biases in micro and macro expression spotting and suggests methods to detect them. In addressing this challenge, we introduce a causal graph that elucidates the connections among a trained deep learning model, the feature space it acquires, and the resulting outcomes. This causal graph plays a pivotal role in pinpointing potential origins of bias during the training phase. We utilise counterfactual inputs to evaluate model biases, providing advantages in terms of computational efficiency and interpretability when contrasted with in-training debiasing approaches. This makes counterfactual debiasing a promising avenue for addressing biases in machine learning models. Experimental results underscore the effectiveness of this approach in successfully mitigating biases in several state-of-the-art macro and micro-expression spotting methods.**

I. Introduction

Facial emotion and micro-expression detection are fields of study that are very closely related. While they both genuinely uncover the emotions exhibited by the individuals, the actual difference lies in how the emotions are conveyed. Since micro-expressions are spontaneously generated in an unconscious state, it is difficult to conceal or disguise and are usually directly related to genuine emotions, so micro-expressions are more reliable in sentiment analysis and have broad application prospects. The success rate is not high, so a computer is required to recognize micro-expressions automatically. Some early works such as [1] note that microexpressions are essentially leaked facial expressions that are brief and sometimes considered more genuine. Specifically, the study notes that microexpressions are defined by their total duration being less than 500 ms or their relatively short onset duration of 260 ms.

Macro and Micro-expression spotting [2] refers to detecting whether a macro or micro-expression is included in a video stream and marking the start point (onset), peak value (apex) and endpoint (offset) of that specific expression. The onset frame refers to the time when that expression appears; the apex frame refers to the time when the magnitude of that expression is the largest; the offset frame refers to the time when the expression disappears. Identifying and interpreting expressions, especially micro-expressions, can provide insights into emotional states, deception detection, and assessing an individual's genuine reactions.

Bias in machine learning model [3] leads to unfairness and discriminative outcomes, amplifying the inequality towards specific groups of people. Label annotation for images or videos by experts or professionals who aim to assign an accurate label, but biases arise towards some groups will also present underlying labels that are biased [4]. Besides the label, racial bias needs to be mitigated to ensure the network results are objective [5]. Besides that, the medicine field [6], human-computer interaction [7] and software research topics [8] also take fairness under their consideration. All the potential biases above in deep learning models should be taken into account during the experimental and evaluation stages. It promotes transparency, as understanding the sources and types of bias helps explain the decision-making process in the black-box predictions of the machine learning models.

In this paper, our contributions can be summarized as follows:

1) We proposed a method to identify the potential or unseen biases in all variables involved in the experiments.
2) We proposed a novel technique for mitigating the bias in the macro and micro-expressions spotting machine learning model.
3) We verify the effectiveness of the presented method by comparing it with state-of-the-art methods.

II. Literature Review

A. Spotting task in Micro expression

Most present works propose their novelty in the feature extraction and classification model. Optical flow as input features is mainly used in existing works [9], [10], [11], [12], [13] to extract the motion features of each long video. Using optical flow, which estimates the apparent motion of pixels between consecutive frames, allows us to focus on the dynamic changes that occur. Using a convolutional model, Yap et al. [14] proposed a 3D-CNN-based approach that compares each frame with two temporally local reference frames. Another 3D-CNN-based model called SOFTNet is presented by Liong et al.

979-8-3503-0067-3/23/$31.00 ©2023 IEEE

[15], which estimates a score that represents the probability of a frame falling within an expression interval. The graph-based model is yet to be investigated. Only [9] presented an action units (AUs) aware model with the graph embedding function in their model. Yu et al. [16] employed a Temporal Multi-Receptive Field Feature Fusion Module (TMRF3M) and a Local Suppression and Global Enhancement Module (LSGEM) to enhance the precision of spotting short intervals and suppress irrelevant background information. Yang et al. [17] proposed an advanced Concat-CNN model which is capable of capturing the inherent correlations among distinct frames.

B. Casuality and Fairness in Facial Expression

Casual analysis [18] aims to comprehend the causal relationship between variables, focusing on how one variable directly affects another. Gender and racial bias [5], [19] are often examined in previous facial affect classification work. This is partly because of the imbalanced distribution of ethnicities and gender identity in the published datasets. Biased label identification and reduction of this bias are also studied by a few works [20], [4]. Action unit recognition in human faces is crucial in annotating and classifying individuals' genuine emotions. In [21], they utilized domain-incremental learning settings to enhance system fairness while effectively addressing biases arising from uneven data distributions. Cheong et al. [22] presented a framework that used the fast causal inference algorithm to construct a casual relation graph in facial expression recognition. A proposal utilizing Siamese Networks to minimize the disparities between predictions made on the original images and their corresponding counterfactual counterparts is presented in [23]. Chen et al. [24] mitigate the adverse impacts caused by dataset bias with their novel, the Interventional Emotion Recognition Network, which aims to perform backdoor adjustment. This adjustment technique is a fundamental de-confounding method in causal inference. Debiasing in expression spotting tasks is still a new research direction yet to be widely discovered.

III. Methodology

The primary aim of this unbiased decision-making framework is to identify and reduce the bias in spotting models effectively.

A. Macro and Macro expression Spotting

Formally, the problem of micro and macro-expression can be defined as: Given a video I_n we aim to learn a model $M_\theta(.)$ that can identify the onset L_{on}, apex L_{apex}, and the offset L_{off} frames of expression within I_n, θ being the parameters of the model and, n, the number of frames. The output results of the $M_\theta(.)$ given the I_n can be thus represented as as $M_\theta(I_n) = P(L_{on}, L_{apex}, L_{off}|I_n)$. From here on, we refer to the triplet $(L_{on}, L_{apex}, L_{off})$ containing the onset, apex and offset frame as L and it is obtained from the ground truth. The predictions of $M_\theta(.)$ can be falsely impacted by many unwanted factors known as confounders or otherwise, the bias variables.

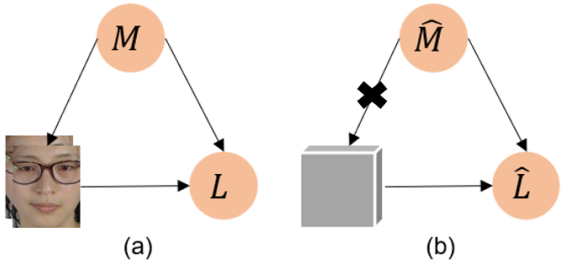

Fig. 1. A causal relation graph akin to Pearl's [25] is established among the key elements: the *trained model* M, the extracted features, and *the outcome* L. (a) It is important to observe that this causal graph illustrates how the trained model M can exert influence over both the learned features and the outcome L." Thus, it acts as a confounder in the relationship between the "feature space" and L. (b) To gain insights into the genuine causal connection of "feature space" $\rightarrow L$," we employ backdoor adjustment, an approach that intervenes using the counterfactual blank frames denoted by the shaded feature in this context.

B. Causal Formulation of Bias

The biased predictions of a model can be formulated as the following conditional probability shown in the equation below:

$$P(L|I_n) = \sum_{n=1}^{C} P(L|I_n, c)P(c|I_n) \tag{1}$$

The factorization described above is aware of the causal graph depicted in Figure 1, which illustrates the relationship between various components. It demonstrates that the expected outcome $P(L|I_n)$ is influenced by confounding factors c. Confounders are the factors that influence both the independent and dependent variables, i.e., the expected outcome. They are often factors that are not directly measured or controlled for in the study but can influence the outcome. The graph in Figure 1 represents the interconnections among the trained model $M_\theta(.)$, the learned features B, and the expected outcome L. It indicates that the trained model $M_\theta(.)$ is a confounder that impacts both the learned features B and the outcome L. Specifically, the relationship depicted as $B \leftarrow M \rightarrow L$ suggests the existence of a backdoor path or confounding path, where $M_\theta(.)$ indirectly affects the outcome L through B. This indirect path complicates understanding the complete or isolated effect of B on L. Moreover, when a biased model $M_\theta(.)$ is employed, the learned features B also tend to be biased.

To address this issue and isolate the effect of $M_\theta(.)$ from that of $L \rightarrow B$, we utilize Pearl's backdoor adjustment strategy [26]. This strategy allows us to disentangle the influence of $M_\theta(.) \rightarrow B$ by explicitly assigning a value to B. In causal theory, this intervention is known as the "do(.)" operation, where we do or, in other terms, set the variable of interest to a particular value. Below, we showcase the do operation-based debiasing technique. Please note that in practice, we need more complete knowledge of all the confounding factors contributing to bias. Thus, it is impossible

to determine the entire set of confounders, and we can only rely on a limited subset that is known or observed. In this work, we work on debiasing the **dataset-based biases**.

C. Mitigation of bias

This study examined how the model performs in classifying offset and onset frames. We discovered the presence of dataset biases within the models, where certain characteristics of the input training data are incorrectly associated with specific outcomes. To delve deeper into this matter, we investigated by manipulating the features B. Specifically, we set them to blank feature frames I_{0n} that do not contain any meaningful feature information. This manipulation is denoted as $M(L|do(I_n = I_{0n}))$. In this context, I_{0n} is referred to as a counterfactual input, which enables us to assess how the model performs when presented with no information at all [27].

Our expectation was that, given the absence of relevant information, the model $M_\theta(.)$ would not be able to predict L_{on}, L_{apex}, and L_{off}. However, our experimental results indicate that the model still predicts these labels for blank frames, suggesting that the model has learned the biases present in the dataset.

Following are the biases that we observe in the current models. During the prediction of the offset frame L_{off}, the model tends to select frames that are closer to the end of the total frame length. As a result, even if the expression in the video ends earlier, the model would still primarily predict the last frames as potential candidates for the offset frame. In addition, the models tend to classify the onset frame as taking place approximately 30-40 frames prior to the offset frame. Consequently, rather than identifying them as micro-expressions, the models are more inclined to categorize these I_{0n} frames as macro-expressions. The fact that there is a consistent pattern of assigning specific frames and types of expressions in the prediction results implies that the models rely on external factors that are unrelated to the inherent characteristics of the expressions for their classification. Both $M(L|I_n)$ and $M(L|do(I_n = I_{0n}))$ generate a probability distribution P for each frame, indicating the likelihood of it being classified into any of the frame types within L. The shape of P depends on the model outcomes. In this paper, we refer to these probabilities as:

$$P_I = \{pr_{s,n}, pr_{e,n}, pr_{a,n}, pr_{t,n}\} \tag{2}$$

I is the type of testing inputs which is I_{0n} or I_n. $pr_{s,n}, pr_{e,n}, pr_{a,n}, pr_{t,n}$ denotes the set of probabilities for onset, offset, apex and expression type. With the method above, after addressing a bias, we could use Pearl's backdoor criterion [25] to increase the fairness in the model. In order to remove the bias, we first record the original biased probabilities P_{I_n} for a given input video I_n and then debias the output probability distribution by subtracting $P_{I_{0n}}$ from it,

$$f(l|\mathbf{v}) = M(L|I_n) - \lambda M(\hat{L}|do(I_n = \hat{I_{0n}})) \tag{3}$$

here, λ_{param} is the hyperparameter that mitigates the plausible sources of biases. λ values differ for every set of P to maximize the pertinency of the debias method. This method is known as a counterfactual debiasing method and is performed during the inference time, which is less time-consuming and flexible. This is also a more interpretable method of debiasing.

IV. Experiments

A. Datasets Available

1) Real-World Data: The human facial expression is usually hard to capture in the wild because the unstable environment will influence one's emotions and increase inaccuracy when we label the captured samples. Therefore, the human emotion datasets will usually be recorded in an uninterrupted studio environment and specific videos will be used to trigger particular emotions. Collecting such datasets for micro-expressions (ME) is even more difficult as they are challenging to induce naturally. Therefore, the current samples from the real world are limited. There are a few macro and micro-expression spotting databases that are constantly being utilized which are CAS(ME)^2 [28], CAS(ME)^3 [29], SMIC-E-Long Video (SMIC-E)[30], SAMM-Long Video (SAMM-LV)[31] and 4D micro-expression dataset(4DME) [32].

2) Trainable Synthetic ME Dataset: Since the data from the real persons have an imbalanced number of samples in categories and the dataset size is too small for training purposes, Y Liu et al. [33] introduced the MiE-X dataset synthesized from a generative adversarial network model. This dataset is not suitable for training or testing in a spotting task. Each individual and each of the three emotion classes only consists of three micro-expression samples and three macro-expression samples for each combination.

This experiment used the CAS(ME)^2 and SAMM-LV dataset as training and testing inputs. CAS(ME)^2 includes long videos and cropped expression samples. It has 87 long videos capturing spontaneous macro-expressions and micro-expressions. SAMM-LV consists of 147 videos that contain a total of 343 macro-expressions and 159 micro-expressions. The emotion labels in the databases are based on a combination of action units (AUs) and the emotion types of the videos that evoke the emotions. Both datasets are collected in a controlled environment.

B. Baselines

We employ two state-of-the-art methods in our experimental setup: the ABPN framework and the AUW-GCN architecture. These methods are widely recognized for their effectiveness in the field.

- **Apex and Boundary Perception Network (ABPN) [10]**. Part of this work's important novelty is that calculating optical flow differences mitigates the influence of head movement and other facial areas on microexpression spotting. Additionally, they employ 1D convolutional layers to extract temporal features and introduce the probability evaluation module to estimate the auxiliary probability of each frame belonging to an apex or boundary frame.

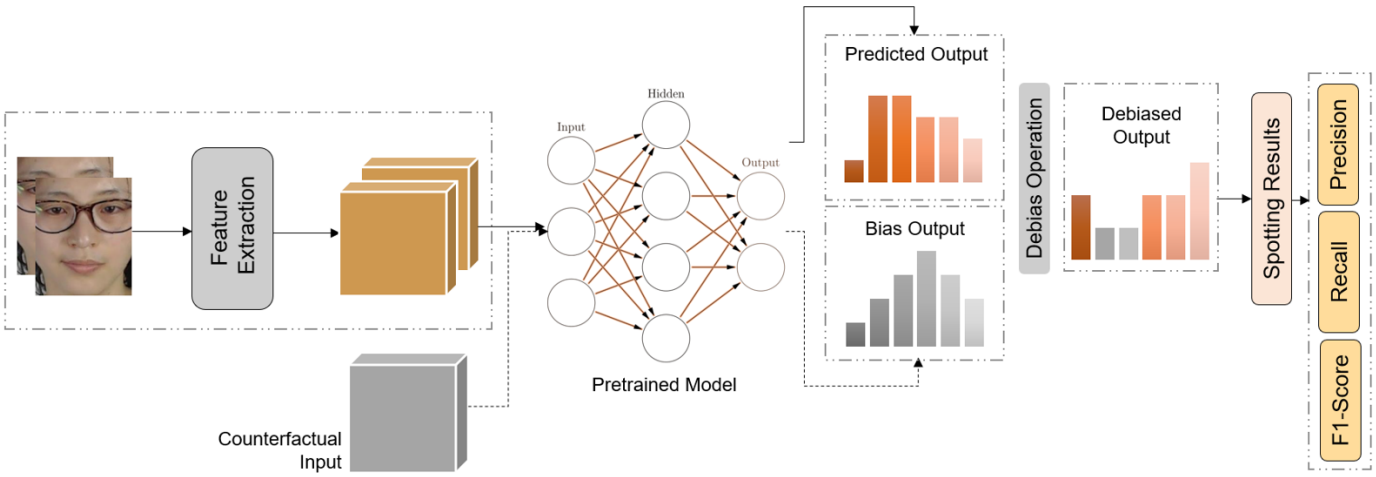

Fig. 2. The diagram illustrates the structure of our proposed debiasing technique. During inference, we gather the predicted output by passing a test sample through a trained model. Subsequently, we introduce the counterfactual input, as detailed in Section III, and capture its predicted output, which represents the biased output. To achieve a debiased outcome, we subject the predicted output distributions of the test sample and the counterfactual input to a debiasing operation.

- **Action-Unit-aWare Graph Convolutional Network (AUW-GCN) [9]**. This work proposed an action units aware model in which AU-related statistics are encoded into the GCN. AUs are used to build the adjacency matrix and multiply it with the features of the video frames to complete the spatial encoding phase. The spatial-temporal learning architecture in this paper minimized the loss in the learning process and increased the results significantly.

C. Data-Preprocessing

Video frames pre-processing methods and model parameters remain unchanged from the original works to ensure optimal performance without introducing unaccounted biases. The implementations of both models are based on the PyTorch library.

Before implementing Equation 3, we prepared blank frames I_{n0} as the counterfactual inputs and used them as test inputs for the pre-trained model. After passing I_{n0} to the model, the $P_{I_{n0}}$ of the counterfactual testing samples are recorded. Figure 2 concludes the steps to mitigate the identified bias and re-run the experiments with the pre-trained weights.

D. Metrics

In line with the baselines, Leave-One-Subject-Out (LOSO) validation is used in our experiments and the evaluation metric is the F1 score. It is commonly used for imbalanced sample datasets because it provides a balanced measure of a model's performance by considering both the ability to correctly identify positive instances (precision) and capture all positive instances (recall). This choice allows for a fair and reliable assessment of our model's performance.

Overall results in table I and II refer to the F1 score for both macro and micro-expressions. The overall F1 score is as shown in Equation 6:

$$F1_{ME} = \frac{TP_{ME}}{TP_{ME} + \frac{1}{2}(FP_{ME} + FN_{ME})} \tag{4}$$

$$F1_{MaE} = \frac{TP_{MaE}}{TP_{MaE} + \frac{1}{2}(FP_{MaE} + FN_{MaE})} \tag{5}$$

TP, FP and FN are the number of true positives (TP), false positives (FP), and false negatives (FN) produced by the model on the test data. MaE and ME denote the macro expression and micro-expression, respectively.

$$F1_{overall} = F1_{ME} + F1_{MaE} \tag{6}$$

E. Results and Dicussion

Table I and II shows the results in the F1 score before and after debiasing the ABPN and AUW-GCN model. After applying the proposed method and fine-tuning the hyperparameters, the F1 scores for both methods show improvement in CAS(ME)^2 and SAMM-LV datasets. CAS(ME)^2 reflects a better performance with the framework partly because it is an RGB dataset, unlike the SAMM-LV dataset. The contextual information in a video's environment can influence a model's learning process, potentially leading to biases in the dataset and preventing the model from fully capturing essential features in the frames. The surrounding environment, including lighting conditions, background elements, and spatial relationships, can impact the appearance and interpretation of facial expressions.

Our findings highlight the importance of addressing dataset biases in expression spotting tasks, particularly in micro expressions' video sequences where facial part motion intensity is minimal. The susceptibility of microexpressions to dataset biases calls for greater scrutiny when collecting training datasets, ensuring they are diverse and representative of real-world scenarios. Furthermore, fine-tuning hyperparameters can enhance performance by enabling models to overcome biases and improve their ability to spot accurate frames.

F. Limitations

Various spotting experiments have been conducted in previous works with real-world data. Nevertheless, the number of samples in each dataset is much smaller than the facial expression recognition benchmark size, as natural micro-expressions are challenging to trigger. Consequently, we need to synthesize more samples to achieve fairer experiment results. Moreover, the causal relation between all variables is denoted with prior knowledge or a hand-crafted method. A more robust model to prove the source of bias is needed to gain reliable outcomes.

V. CONCLUSION

This study introduces an innovative debiasing approach tailored for the task of facial expression spotting. We commence by addressing prevalent biases commonly observed in micro and macro-expression spotting, with a primary focus on mitigating dataset-induced bias. Subsequently, we outline methods designed to detect the presence of such bias. Employing a causal graphical model, we delve into potential sources of bias and utilize counterfactual inference to scrutinize the model for any inherent bias, as postulated in. Notably, we observe that a model trained on a biased dataset acquires bias within its feature space. To rectify this, we employ non-informative counterfactual blank frames to execute a back-door adjustment. Crucially, the counterfactual intervention is executed during inference, rendering our debiasing method efficient in terms of both time and space. The insights gained through counterfactual inference enable us to identify and subsequently correct biases present in the model's predicted outputs. Our experimental results vividly illustrate the efficacy of our approach in successfully alleviating biases across a range of state-of-the-art macro and micro-expression spotting methods.

***Abstract*— Estimating the interference-plus-noise covariance matrix (INCM) is critical for the robustness of the minimum variance distortionless response (MVDR) beamformer. Existing INCM reconstruction methods are computationally intensive and not suitable for real-time speech separation. We propose a singular value decomposition (SVD) based INCM reconstruction method for speech separation. The spatial covariance matrix (SCM) for each source is obtained by rank-1 approximation using the nominal steering vector (SV) or the pre-measured relative transfer function (RTF). The INCM used to separate each source is reconstructed as the sum of the covariance matrices of interference and spherical isotropic noise. The proposed method is evaluated using the mixed signal received by a circular array with six microphones placed in a simulated reverberation chamber. The results show that the proposed method has comparable sound quality performance to the reference method, but requires much less computation.**

I. INTRODUCTION

Speech separation refers to the problem of extracting one or more target utterances while eliminating interfering utterances and noise [1]. It is a key pre-processing step for noise-robust automatic speech and speaker recognition, and its applications include enabling intelligent robots to understand speech content and interaction intention when multiple people are speaking simultaneously.

In recent years, deep learning methods has been widely studied for speech separation by exploring single-channel features [2]-[4], multi-channel features [5][6], and multi-modal features [7][8]. Most devices today feature a microphone array consisting of two or more sensors, but not all of them have cameras. Adaptive beamforming as a linear spatial filter is still one of the most efficient and effective front-end processing techniques for robust speech separation in practical scenarios [9]-[11].

Various robust adaptive beamformers with different optimization criteria have been proposed, such as multi-channel Wiener filter (MWF), minimum variance distortionless response (MVDR), and linear constraint minimum variance (LCMV). Estimating acoustic parameters, such as the acoustic transfer function (ATF) and the interference-plus-noise covariance matrix (INCM), from the mixed speech observations are critical for the robustness of these beamformers [12] [13]. Although many methods for improving the robustness of beamformers can be found in the literature, such as diagonal loading [14], eigenspace projection [15], worst-case optimization [16], and covariance matrix tapering [17], estimating the ATF and INCM in the presence of multiple sources is still an open research question.

Covariance subtraction-based and covariance whitening-based methods for estimating relative transfer functions (RTFs) typically require knowledge of time frames in which only one

desired source is active [18] or estimation of speech presence probabilities (SPPs) [19]. However, estimating the SPP per speaker in dynamic scenes raises more problems, such as clustering and permutation alignment [20].

The INCM used to separate the desired source is defined as the sum of the covariance matrices of interference and all possible noises. Gu and Leshem [21] proposed an INCM reconstruction method by integrating a Capon spectral estimator over an angular sector excluding the direction of arrival (DOA) of the signal of interest. Yuan and Gan [22] proposed an INCM reconstruction method using principal eigenvalue vectors. Although many efforts have been made to reduce the computational complexity [23] [24], existing INCM reconstruction methods are still not suitable for real-time speech separation.

Generalized singular value decomposition (SVD) for real-time sound source localization has been shown to significantly reduce computation while maintaining noise robustness in localization [25]. Observing that SVD provides the same orthogonality as eigenvalue decomposition as well as a more efficient way of computing matrix inverses, we propose in this work an SVD-based INCM reconstruction method for real-time speech separation. First, we employ a recursive smoothing method to estimate the covariance matrix of the mixed speech observations. The SVD of the covariance matrix is then used to compute its inverse and estimate the variance of each source and noise. Furthermore, the spatial covariance matrix (SCM) for each source is obtained by its rank-1 approximation. The final INCM used to separate each source is full rank by summing the covariance matrices of the interference and spherical isotropic noise. Finally, the coefficients of the separation matrices are calculated by the MVDR method.

The remainder of this paper is organized as follows. In Section II, we describe the proposed adaptive beamforming method for speech separation based on INCM reconstruction. We then provide the experimental setup and evaluation results in Section III. Conclusions are given in Section IV.

II. Proposed Adaptive Beamformer

A. Signal Model

Suppose a recorded sound scene consists of D desired sources and a microphone array with M isotropic transducers. The microphone index and source index are denoted by i and j, respectively. The short-time Fourier transform (STFT) of the multichannel signal received by the microphone array can be expressed as

$$\boldsymbol{y}(t,f) = \sum_{j=1}^{D} \boldsymbol{a}_j(f) S_j(t,f) + \boldsymbol{N}(t,f), \quad (1)$$

where $S_j(t,f)$, $j = 1,2,\dots D$, is the j-th desired source, $\boldsymbol{a}_j(f)$ is the ATF of j-th source, $\boldsymbol{N}(t,f)$ is the noise vector including all undesired sources, noise and late reverberation, and

$$\boldsymbol{y}(t,f) = [Y_1(t,f) \quad Y_2(t,f) \quad \dots \quad Y_M(t,f)]^T, \quad (2)$$

where $Y_i(t,f)$, $i = 1,2,..M$ is the signal received by the i-th microphone at time-frame index t and frequency index f, T denotes the regular matrix transpose. Note that we assume that each speaker's ATF is time-invariant.

Speech separation is applied by using spatial filters as

$$\boldsymbol{Z}(t,f) = \boldsymbol{W}^H(t,f)\boldsymbol{y}(t,f), \quad (3)$$

where $\mathbf{W}(t,f)$ is the separation matrix with weighting coefficients, H denotes the complex conjugate matrix transpose, and $\boldsymbol{Z}(t,f)$ is the vector of separated signals.

B. INCM Reconstruction

At the initial time step, the $M \times M$ covariance matrix $\boldsymbol{\Phi}_{\text{mix}}$ of the mixed signal is initialized as

$$\boldsymbol{\Phi}_{\text{mix}}(0,f) = \boldsymbol{\Gamma}_{0,\pi}(f) + \varepsilon(f)\boldsymbol{I}_M, \quad (4)$$

where $\boldsymbol{I}_M$ is an $M \times M$ identity matrix, $\varepsilon(f)$ is a frequency-dependent regularization parameter, $\boldsymbol{\Gamma}_{0,\pi}(f)$ is the covariance matrix of spherical isotropic noise [11],

$$\boldsymbol{\Gamma}_{0,\pi}(f) = \frac{1}{4\pi}\int_0^{2\pi}\int_0^{\pi} \boldsymbol{d}(\theta,\phi,f)\boldsymbol{d}^H(\theta,\phi,f)\sin\theta\, d\theta\, d\phi, \quad (6)$$

where $\boldsymbol{d}(\theta,\phi,f)$ is the array manifold vector, θ is the evaluation angle measured from the positive z-axis, and ϕ is the azimuth angle measured from the x-axis to the y-axis. The covariance matrix of spherical isotropic noise models late reverberation effects [1].

At time step t, $\boldsymbol{\Phi}_{\text{mix}}$ is obtained by recursive smoothing as

$$\boldsymbol{\Phi}_{\text{mix}}(t,f) = \alpha_1\boldsymbol{\Phi}_y(t-1,f) + (1-\alpha_1)\boldsymbol{\Phi}_y(t,f), \quad (5)$$

where $\boldsymbol{\Phi}_y(t,f) = \boldsymbol{y}(t,f)\boldsymbol{y}^H(t,f)$, α_1 is a smoothing parameter, $0 < \alpha_1 < 1$.

The parameter $\varepsilon(f)$ tries to find a good compromise between supergain and white noise amplification. Since white noise amplification is much worse at low frequencies than at high frequencies [11], we choose larger values of $\varepsilon(f)$ at low frequencies and smaller values at high frequencies.

SVD of the covariance matrix of the mixed signal gives

$$\boldsymbol{\Phi}_{\text{mix}}(t,f) = \boldsymbol{U}\boldsymbol{\Sigma}\boldsymbol{V}^H, \quad (7)$$

where $\boldsymbol{U}$ and $\boldsymbol{V}$ are left- and right-singular vectors, respectively, which are unitary and mutually orthogonal, $\boldsymbol{\Sigma} = \mathrm{diag}\{\varsigma_1, \varsigma_2, \ldots \varsigma_M\}$, is a diagonal matrix containing the singular values in descending order.

For the noise covariance matrix, the noise power is simply estimated as the mean of the $(M-D)$ smallest singular values as

$$\sigma_n^2(t,f) = \frac{\mathbf{1}}{M-D}\sum_{i=M-D}^{M}\varsigma_i. \tag{8}$$

In order to reduce the amount of calculation, the inverse matrix of the $\boldsymbol{\Phi}_{\mathrm{mix}}$ is obtained from singular values and vectors as

$$\boldsymbol{\Phi}_{\mathrm{mix}}^{-1}(t,f) = \boldsymbol{V}\boldsymbol{\Sigma}^{-1}\boldsymbol{U}^H, \tag{9}$$

where $\boldsymbol{\Sigma}^{-1} = \mathrm{diag}\{1/\varsigma_1, 1/\varsigma_2, \ldots 1/\varsigma_M\}$.

The signal variance of the j-th source is estimated as

$$\boldsymbol{\sigma}_j(t,f) = 1/\left(\bar{\boldsymbol{a}}_j{}^H(f)\boldsymbol{V}\boldsymbol{\Sigma}^{-1}\boldsymbol{U}^H\bar{\boldsymbol{a}}_j(f)\right), \tag{10}$$

where $\bar{\boldsymbol{a}}_j$ can be pre-measured RTF vectors or just the nominal SVs. In this work, the pre-measured RTFs are obtained when only the one of desired sources is active, and normalized as [26]

$$\bar{\boldsymbol{a}}_j(f) = e^{-\mathbb{j}\angle \boldsymbol{u}_{1j}(f)}\,\boldsymbol{u}_j(f)/\left\|\boldsymbol{u}_j(f)\right\|, \tag{11}$$

where $\boldsymbol{u}_j(f)$ is the first column of the left-singular vectors corresponding to the largest singular value, $\angle\boldsymbol{u}_{1j}(f)$ is the phase of the first element of $\boldsymbol{u}_j(f)$, $\|\cdot\|$ is the Euclidean norm and $\mathbb{j} = \sqrt{-1}$. The nominal SVs is written as

$$\bar{\boldsymbol{a}}_j(f) = \boldsymbol{d}(\theta_j, \phi_j, f)/d_1(\theta_j, \phi_j, f), \tag{12}$$

where d_1 is the SV of the first microphone, which has been chosen as the reference channel. The performance of two choices of $\bar{\boldsymbol{a}}_j$ is evaluated in Section III.

The SCM of the j-th source is obtained by the rank-1 approximation [27] as

$$\boldsymbol{\psi}_j(t,f) = \boldsymbol{\sigma}_j(t,f)\bar{\boldsymbol{a}}_j(f)\bar{\boldsymbol{a}}_j{}^H(f). \tag{13}$$

The INCM for the k-th source is reconstructed as

$$\boldsymbol{\Phi}_k(t,f) = \sum_{j=1,j\neq k}^{D}\boldsymbol{\psi}_j(t,f) + \sigma_n^2(t,f)\boldsymbol{I}_M. \tag{14}$$

The weighting coefficients used to separate the k-th source are given by the MVDR formula,

$$\boldsymbol{w}_k(t,f) = \eta^{-1}\bar{\boldsymbol{\Phi}}_k^{-1}(t,f)\bar{\boldsymbol{a}}_k(f), \tag{15}$$

where η is a scalar,

$$\eta = \bar{\boldsymbol{a}}_k{}^H(f)\bar{\boldsymbol{\Phi}}_k^{-1}(t,f)\bar{\boldsymbol{a}}_k(f), \tag{16}$$

and

$$\bar{\boldsymbol{\Phi}}_k(t,f) = \alpha_2\boldsymbol{\Phi}_k(t,f) + (1-\alpha_2)\boldsymbol{\Phi}_{\mathrm{mix}}(0,f), \tag{17}$$

where $0 \le \alpha_2 \le 1$. This allows for better adaptation to reverberant environments via a full-rank spatial covariance matrix. When $\alpha_2 = 0$, the method degenerates to a fixed beamformer. The separation matrix contains $\boldsymbol{w}_k$ as columns,

$$\mathbf{W}(t,f) = [\boldsymbol{w}_1 \quad \boldsymbol{w}_2 \quad \ldots \quad \boldsymbol{w}_D]. \tag{18}$$

The interfering speech attenuation factor (ISAF), ξ_{n}, is defined as

$$\xi_{\mathrm{n}} = 10\log_{10}(\sigma_I^2/\sigma_{FI}^2), \tag{19}$$

where σ_I^2 and σ_{FI}^2 are the variance of the interfering speech before and after beamforming. A larger ISAF value indicates better interference suppression.

III. Experimental Setup and Evaluation

A. Experimental Setup

A circular array with six microphones was placed in a 40 m × 50 m × 4 m reverberation room. The radius of the array was 0.035 m. The *x*0*y* plane was set on the floor of the room. The *x* and *y* coordinates of the center of the microphone array were chosen randomly in the range $[10,30]$ meters. The height of the microphone array was set to 1.65 m. The distance from the center of the microphone array to all sound sources was 1 m. The height of all sources was set to 1.70 m. Two sound sources were mixed in the experiment. The azimuth angle of the first source was chosen randomly. The azimuth of the second source was chosen to be 45° from the first source. The signal-to-interference ratio (SIR) was chosen randomly in the range $[0,3]$ dB. The reverberant room with a T_{60} time of 600 ms was simulated by the image source method [28] [29]. All audio was trimmed to 3 seconds at a sampling frequency of 16 kHz.

For far-field point sources in an anechoic chamber, the array manifold vector of a circular array can be written as

$$\boldsymbol{d}(\theta,\phi,f) = \begin{bmatrix} e^{(\mathbb{j}H_e\sin\theta\cos(\phi-\varphi_1))} \\ \vdots \\ e^{(\mathbb{j}H_e\sin\theta\cos(\phi-\varphi_M))} \end{bmatrix}, \tag{20}$$

where $H_e = 2\pi f r_{\mathrm{mic}}/c_0$, r_{mic} is the radius of the array, φ_i are the azimuth angles of the microphones,

$$\varphi_i = 60(i-1)\pi/180, i = 1,2,..M. \tag{21}$$

Parameters for the beamformer were $\alpha_1 = (L-1)/(L+1)$ and $\alpha_2 = 0.9$, where $L = 320$ was the number of STFT points. Half-overlapping Hanning windows were used. $\varepsilon(f)$ was chosen empirically to decrease linearly from 0.01 to 0.001 as the frequency increases from 0 to 8 kHz. The sound speed is 343 m/s. It is assumed in this work that the ground truth DOA of each sound source is known.

B. Results and Discussion

The proposed method was evaluated and compared with reference methods using five performance metrics: perceptual evaluation of speech quality (PESQ) score [30], short-time objective intelligibility (STOI) [31], scale-invariant signal-to-distortion ratio improvement (SI-SDRi) [32], ISAF, and online computational time (OCT). OCT is the average time for online processing a 6-channel, 200 ms signal on an Intel Xeon processor Cascade Lake@3.0GHz PC. In practice, the covariance matrix of the observed signal is updated every 10 ms, while the beamformer weights are updated every 200 ms. All of the results were averaged over 100 cases with different speeches and DOA combinations.

The methods for comparison were:

a) Adaptive MVDR beamformer without INCM reconstruction, i.e., $\alpha_2 = 0$.
b) Adaptive MVDR beamformer with INCM reconstruction as described in [22].
c) The proposed adaptive MVDR beamformer with INCM reconstruction using nominal SVs.
d) The proposed adaptive MVDR beamformer with INCM reconstruction using pre-measured RTFs.

For a fair comparison, the coefficients of the separation matrices for all these methods were initialized using the initial SCM, $\mathbf{\Phi}_{\text{mix}}(0, f)$ in (4). The reference signal for performance evaluation was chosen as the first channel of the desired speech received by the microphone array.

Table 1 lists the mean PESQ, STOI, SI-SDRi, and OCT for each method. From Table 1, we find that the quality of the speech obtained by MVDR beamformers with INCM reconstruction is significantly improved compared to that without INCM reconstruction.

TABLE I. PERFORMANCE COMPARISON

Method	Metrics				
	PESQ	STOI	ISAF (dB)	SI-SDRi (dB)	OCT (ms)
MVDR without reconstruction	1.41	0.86	8.50	1.88	**4.56**
MVDR with reconstruction as in [22]	1.75	0.93	13.41	**7.86**	951.20
Proposed method with reconstruction using SVs	1.78	0.93	14.11	7.41	60.15
MVDR with reconstruction using pre-measured RTFs	1.78	0.93	**14.61**	7.40	60.15

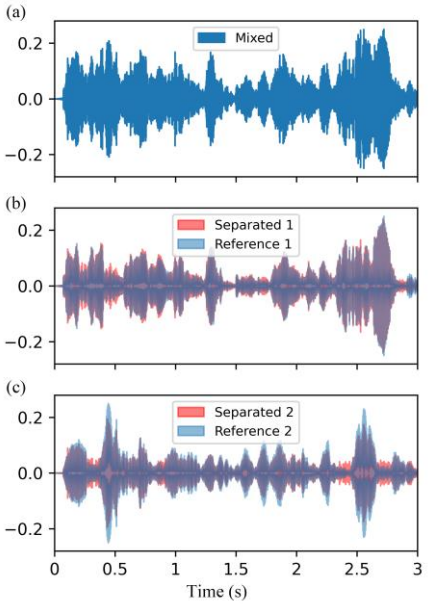

Fig. 1 Waveforms of the (a) mixed signal, (b) separated and clean reference signal of utterance 1, and (b) separated and clean reference signal of utterance 2.

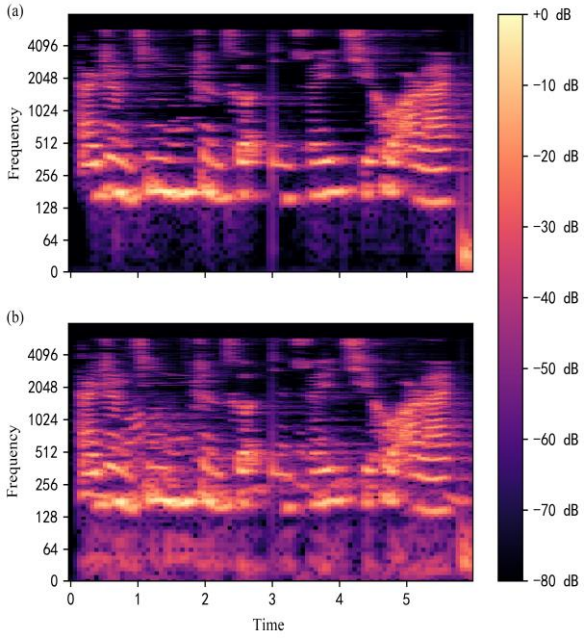

Fig. 2 Log-frequency power spectrogram of the desired speech: (a) the clean reference signal; (b) the signal estimated from the mixture.

The sound quality of the separated signals obtained by the proposed method is comparable to that of the adaptive MVDR

beamformer with INCM reconstruction described in [22]. However, the OCT of the proposed method is greatly reduced and less than the length of the audio, which is essential for real-time speech separation. Furthermore, we find that the proposed adaptive MVDR beamformer achieves the best ISAF performance using pre-measured RTFs.

Fig. 1 shows the time-domain waveforms of the mixed signal, separated utterance 1, separated utterance 2, and the clean reference signal for utterance 1 and 2, respectively. The waveforms for utterance 1 and utterance 2 are mostly recovered from the mixture, although there are some mismatches in some time frames.

Fig. 2 shows the log-frequency power spectrogram plots of the clean reference signal for utterance 1 and the separated utterance 1. The power spectrogram plot reveals a small amount of low-frequency noise and interference remaining after beamforming.

IV. Conclusions

We proposed an SVD-based INCM reconstruction method for beamforming-based speech separation. The SCM for each source is obtained by the rank-1 approximation using the nominal SVs or the pre-measured RTFs. The inverse of the covariance matrix of the mixed speech observations is obtained directly from the results of SVD. The INCM used to separate each source is reconstructed as the sum of the covariance matrices of interference and spherical isotropic noise. Experimental results show that the proposed adaptive beamformer based on INCM reconstruction for speech separation exhibits comparable sound quality in terms of PESQ, STOI, and SI-SDRi. ISAF is improved by using the pre-measured RTFs for INCM reconstruction. Most importantly, the computational time is greatly reduced and less than the frame length of the audio. Therefore, the proposed method is suitable for real-time speech separation.

***Abstract*—Our proposed correlated multi-level optimization approach enhances speech recognition performance for high-performance acoustic models in real-world applications. By combining mean squared error of mask, scale-invariant source-to-noise ratio, and cross-entropy loss functions, as well as adopting Pearson correlation coefficient as a part of the optimization goal to measure the correlation between them, our approach aims to not only reduce the value of each loss during training but also increase the correlation between them. Experimental results on continuous Mandarin recognition in mobile phone scenarios show that our approach achieves a relative reduction of about 25.29% in the average character error rate across five signal-to-noise ratio levels. Notably, our approach improves objective perception qualities and intelligibility measures, as well as recognition accuracies, surpassing some advanced speech enhancement techniques in the context of automatic speech recognition.**

I. Introduction

Speech enhancement (SE) aims to extract clean speech from noisy speech by reducing or suppressing background noises [1]. However, conventional SE techniques [2]–[6] often struggle to estimate noise characteristics and track non-stationary noises in real-world acoustic conditions. In recent years, data-driven SE approaches based on deep neural networks (DNNs) have gained popularity [7]–[9]. Thanks to their powerful modeling capability, DNNs can effectively capture the complex relationship between noisy and clean speech [10], and estimate a mask to suppress noise [11]–[13]. These approaches are typically optimized using minimum-mean-squared-error (MMSE) based loss functions and have improved subjective and objective metrics related to perceptual quality.

SE can also be used as a front-end to automatic speech recognition (ASR) systems, which often suffer from degraded performance in real-world environments with adverse acoustic conditions, such as channel distortion and ambient noise. However, most DNN-based SE models have limited impact on reducing ASR word error rate (WER) [7], [14]–[16]. In fact, some studies have reported that SE can even increase WERs when the back-end is a DNN-based model with multi-condition training [17]–[20], due to unseen distortions in enhanced speech that cause mismatches between the training and testing.

One potential solution is to retrain the back-end ASR system by including enhanced speech in the training set [21]. Another approach is to jointly train the front-end SE model and the back-end acoustic model [22]–[24], using methods such as teacher-student learning [25], adversarial training [26], or a combination of both [27]. However, in many real-world applications, the ASR models may be provided by a third party and their parameters cannot be re-estimated. Therefore, it is important to explore advanced loss functions that can optimize the SE models while using fixed ASR models.

Given the aforementioned constraints, reinforcement learning (RL) [28] has emerged to optimize SE models directly based on recognition results. For example, in [29], two DNNs using MetricGAN [30] were developed, one for speech enhancement and the other for mimicking the output CERs obtained from an ASR system. In [31], a cross-entropy-guided measure (CEGM) was proposed to evaluate ASR performance and optimize SE model. CEGM calculates the cross entropy of state posteriors between enhanced and clean speech, which are obtained from the outputs of the DNN-HMM (Hidden Markov Model) acoustic model. However, it was shown that CEGM is challenging for enhancement models to improve recognition performance when the back-end acoustic models are more powerful, as is typically the case in real-world ASR applications. Additionally, CEGM-enhanced speech is no longer intelligible. Therefore, there is a pressing need for SE models that can improve both recognition performance and perceptual quality.

This paper addresses the issue that using the conventional CEGM alone is inadequate for optimizing SE models with high-performance back-end ASR models. We propose a correlated multi-level (CML) optimization approach that utilizes a sequential loss function comprising four terms: mean squared error between the estimated and ideal ratio masks (MSE-M), scale-invariant source-to-noise ratio (SISNR) between the reconstructed and clean speech waveforms, cross-entropy between the state posteriors of the acoustic model evaluated using the reconstructed and clean speech features (CEGM), and Pearson correlation coefficients (PCCs) [32] between MSE-M, SISNR, and CEGM. By utilizing these various loss functions,

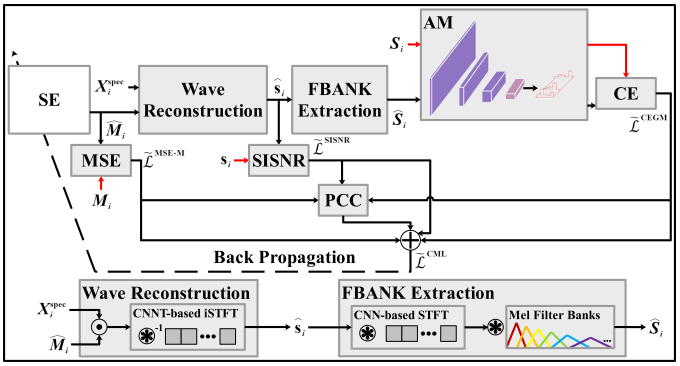

Fig. 1. Illustration of correlated multi-level speech enhancement.

our approach aims to enhance the perceptual quality and recognition accuracy of the enhanced speech.

CEGM facilitates the transfer of acoustic knowledge from pre-trained models to the SE model, reducing distortions that impact recognition accuracy. MSE-M and SISNR address optimization challenges brought by the back-end acoustic model, utilizing magnitude masks and reconstructed waveforms. PCC considers the interplay between different loss functions, working to increase their correlation. Moreover, our proposed CML approach overcomes the limitations of CEGM by not solely relying on back-end models and explicitly modeling the correlation between different loss functions. Our experimental results show that the proposed approach significantly improves speech recognition performance and our reconstructed speech exhibits improved perceptual quality compared to the conventional MMSE-enhanced speech.

II. Correlated Multi-Level Speech Enhancement

Different from CEGM in which the front-end SE model is limited to output the desired acoustic features to the back-end ASR model, CML processes the noisy log power spectra (LPS) feature $X_i \in \mathbb{R}^{T\times F}$ and outputs a magnitude mask $\widehat{M}_i \in \mathbb{R}^{T\times F}$:

$$\widehat{M}_i = \mathcal{F}(X_i; W) \tag{1}$$

where i is the sample index in the current batch. $\mathcal{F}$ and W denote the SE model and the corresponding parameter set, respectively. The values of $\widehat{M}_i$ range from 0 to 1. T and F denote the time length and the number of frequency bins of spectrum feature, respectively. In this study, F is set as 201 by default. Then the wave reconstruction module uses $\widehat{M}_i$ to filter the noisy spectrum $X_i^{\mathrm{S}} \in \mathbb{C}^{T\times F}$ and the filtered spectrum is fed to a 1D transposed convolution layer to reconstruct waveform:

$$\widehat{\mathbf{s}}_i = \mathcal{U}(X_i^{\mathrm{spec}}, \widehat{M}_i; W_{\mathrm{stft}}) \tag{2}$$

where $\widehat{\mathbf{s}}_i \in \mathbb{R}^L$ denotes the reconstructed wave of length L. $\mathcal{U}$ denotes the wave reconstruction module and W_{stft} denotes the forward weight of STFT which is also the parameter set of the 1D transposed convolution. The feature extraction module $\mathcal{E}$ takes $\widehat{\mathbf{s}}_i$ as input and outputs the FBANK feature $\widehat{S}_i \in \mathbb{R}^{T\times F_{\mathrm{mel}}}$:

$$\widehat{S}_i = \mathcal{E}(\widehat{\mathbf{s}}_i; W_{\mathrm{fe}}) \tag{3}$$

where W_{fe} denotes the corresponding parameter set of $\mathcal{E}$, respectively. F_{mel} denotes the numbers of triangular filters and is set as 40 by default in this study. As shown in Figure 1, the FBANK extraction module consists of two 1D convolution layers, where the first 1D convolution layer is used to perform online STFT, and the second 1D convolution layer is used as Mel filter banks. Finally, we adopt the acoustic model of the hybrid DNN-HMM ASR model to perform deep feature extraction. The low-level acoustic feature is mapped to the high-level presentation, i.e., the clustered state posterior probability:

$$\mathrm{p}(\mathbf{h}|\widehat{S}_i) = \mathcal{G}(\widehat{S}_i; W_{\mathrm{am}}) \tag{4}$$

where $\mathbf{h} = \{h_0, ..., h_{I-1}\}$ denotes the clustered HMM states, $\mathrm{p}(\mathbf{h}|\widehat{S}_i) \in \mathbb{R}^{T\times I}$ denotes the posteriors of $\mathbf{h}$ given $\widehat{S}_i$. $\mathcal{G}$ and W_{am} denote the acoustic model and the corresponding parameter set, respectively.

The proposed correlated multi-level loss function $\mathcal{L}_{\mathrm{CML}}$ is calculated as follows:

$$\mathcal{L}^{\mathrm{CML}} = \sum_{i=0}^{N-1} \frac{\widetilde{\mathcal{L}}_i^{\mathrm{MSE-M}} - \widetilde{\mathcal{L}}_i^{\mathrm{SISNR}} + \widetilde{\mathcal{L}}_i^{\mathrm{CEGM}}}{N} - \mathcal{L}^{\mathrm{PCC}} \tag{5}$$

where $\widetilde{\mathcal{L}}_i^{\mathrm{MSE-M}}$ is the normed MSE between $\widehat{M}_i$ and ideal ratio mask (IRM) $M_i \in \mathbb{R}^{T\times F}$:

$$\widetilde{\mathcal{L}}_i^{\mathrm{MSE-M}} = \mathcal{L}_i^{\mathrm{MSE-M}} / \max_{k\in \text{train set}} (|\mathcal{L}_k^{\mathrm{MSE-M}}|) \tag{6}$$

$$\mathcal{L}_i^{\mathrm{MSE-M}} = \sum_{t=0}^{T-1}\sum_{j=0}^{F-1} \frac{(\widehat{m}_{i,t,j} - m_{i,t,j})^2}{TF} \tag{7}$$

where $\widehat{m}_{i,t,j}$ and $m_{i,t,j}$ are the values at t-th time step and j-th frequency bin of $\widehat{M}_i$ and M_i, respectively. N denotes the batch size and is set as 32 by default in this study. k is the sample index in the whole train set. To prevent the loss weight from being affected by the magnitude scale, we divide each element of $\mathcal{L}_i^{\mathrm{MSE-M}}$ by the maximum amplitude calculated from the whole training set, ensuring that the values of $\widetilde{\mathcal{L}}_i^{\mathrm{MSE-M}}$ are also in the range of 0 to 1.

$\widetilde{\mathcal{L}}_i^{\mathrm{SISNR}}$ denotes the normed SISNR between $\widehat{\mathbf{s}}_i$ and the corresponding clean waveform $\mathbf{s}_i \in \mathbb{R}^L$:

$$\widetilde{\mathcal{L}}_i^{\mathrm{SISNR}} = \mathcal{L}_i^{\mathrm{SISNR}} / \max_{k\in \text{train set}} (|\mathcal{L}_k^{\mathrm{SISNR}}|) \tag{8}$$

$$\mathcal{L}_i^{\mathrm{SISNR}} = 10\mathbf{log}\frac{\sum_{\tau=0}^{L-1} s_{i,\tau}^2}{\sum_{\tau=0}^{L-1}[\widetilde{s}_{i,\tau} - s_{i,\tau}]^2} \tag{9}$$

where $\widetilde{s}_{i,\tau} = \widehat{s}_{i,\tau}(\sum_{\tau=0}^{L-1} s_{i,\tau}^2)/(\sum_{\tau=0}^{L-1} \widehat{s}_{i,\tau} s_{i,\tau})$. $\widehat{s}_{i,\tau}$ and $\mathrm{s}_{\mathrm{i},\tau}$ are values at the τ-th time step of $\widehat{\mathbf{s}}_i$ and $\mathbf{s}_i$, respectively. We also apply the same normalization procedure to $\mathcal{L}_i^{\mathrm{SISNR}}$ as we do to $\mathcal{L}_i^{\mathrm{MSE-M}}$.

$\widetilde{\mathcal{L}}_i^{\mathrm{CEGM}}$ is the normed cross entropy between enhanced and clean representations, i.e. $\mathrm{p}_t(h_n|\widehat{S}_i)$ and $\mathrm{p}_t(h_n|S_i)$, which are posteriories of h_n given $\widehat{S}_i$ and S_i at the t-th time step:

$$\widetilde{\mathcal{L}}_i^{\mathrm{CEGM}} = \mathcal{L}_i^{\mathrm{CEGM}} / \max_{k\in \text{train set}} (|\mathcal{L}_k^{\mathrm{CEGM}}|) \tag{10}$$

$$\mathcal{L}_i^{\mathrm{CEGM}} = -\sum_{t=0}^{T-1}\sum_{n=1}^{I-1}\frac{\mathrm{p}_t(h_n|S_i)\mathbf{log}\mathrm{p}_t(h_n|\widehat{S}_i)}{T}. \quad (11)$$

The same normalization procedure is applied to $\mathcal{L}_i^{\mathrm{CEGM}}$ as we do to $\mathcal{L}_i^{\mathrm{MSE}}$ and $\mathcal{L}_i^{\mathrm{SISNR}}$.

Optimizing multiple learning goals simultaneously can result in suboptimal performance. Focusing on reducing one or more loss values to improve performance metrics in evaluation can come at the expense of other metrics. Especially in our work, optimizing for MSE and SISNR can significantly enhance the perceptual quality of speech but may not directly benefit recognition accuracy. Conversely, optimizing for CEGM may improve accuracy but compromise the enhanced speech's perceptual quality. To take into account the interplay between different loss functions, we propose using the PCC as a part of optimization goal to measure the correlation between two loss functions. $\mathcal{L}^{\mathrm{CML}}$ aims to not only reduce the value of each loss during training but also increase the correlation between them. $\mathcal{L}_{\mathrm{PCC}}$ is calculated using all sample in the current batch:

$$\begin{aligned}\mathcal{L}^{\mathrm{PCC}} =&\rho(\widetilde{\mathcal{L}}^{\mathrm{MSE-M}}, \widetilde{\mathcal{L}}^{\mathrm{SISNR}}) + \rho(\widetilde{\mathcal{L}}^{\mathrm{MSE-M}}, \widetilde{\mathcal{L}}^{\mathrm{CEGM}}) \\ &+ \rho(\widetilde{\mathcal{L}}^{\mathrm{CEGM}}, \widetilde{\mathcal{L}}^{\mathrm{SISNR}})\end{aligned} \quad (12)$$

$$\rho(\mathcal{L}^a, \mathcal{L}^b) = \frac{\sum_{i=1}^{N}(\mathcal{L}_i^a - \bar{\mathcal{L}^a})(\mathcal{L}_i^b - \bar{\mathcal{L}^b})}{\sqrt{\sum_{i=1}^{N}(\mathcal{L}_i^a - \bar{\mathcal{L}^a})^2}\sqrt{\sum_{i=1}^{N}(\mathcal{L}_i^b - \bar{\mathcal{L}^b})^2}} \quad (13)$$

Where $\bar{\mathcal{L}^a} = \sum_{i=1}^{N}\mathcal{L}_i^a/N$ and $\bar{\mathcal{L}^b} = \sum_{i=1}^{N}\mathcal{L}_i^b/N$. $\mathcal{L}^a, \mathcal{L}^b \in \{\widetilde{\mathcal{L}}^{\mathrm{MSE-M}}, \widetilde{\mathcal{L}}^{\mathrm{SISNR}}, \widetilde{\mathcal{L}}^{\mathrm{CEGM}}\}$ and $\mathcal{L}^a \neq \mathcal{L}^b$. PCC measures the strength and direction of the correlation.

In this study, we selected the No Embedding Aware Speech Enhancement (NoEASE) [33] model as our SE model. We trained the model using the Adam optimizer [34] for 100 epochs, with early stopping when the validation loss did not improve for 10 epochs. We set the initial learning rate to 0.0003 and reduced it by half during training if the validation loss did not improve for 3 epochs. The best model was selected based on the lowest validation loss.

III. Experiments and Result Analysis

A. Data Set Description

To evaluate the effectiveness of the proposed CML approach, we conducted experiments using two sets of simulated noisy speech data. The first dataset, TcdTimit-Noisy, was used in a previous study [33] and comprises noisy speech with all video components removed. The second dataset is an in-house Mandarin corpus collected using mobile phones in real-world conditions and is referred to as Mandarin-Noisy. This corpus consists of 7,081 utterances from different speakers, with 6,900 utterances randomly selected for training, 85 for validation, and 96 for testing. The noise data used to generate noisy-clean pairs were recorded from real bathrooms, kitchens, balconies, and living rooms, resulting in approximately 81 hours of training data, 3 hours for validation, and 3 hours for testing. Each subset contains different speakers and noise recording rooms, and there are five SNR levels (15 dB, 10 dB, 5 dB, 0 dB, -5 dB) in the training, validation, and test sets.

Table 1
Average PER comparison of SE models trained with different criteria on the TcdTimit-Noisy test set at different SNRs.

Criterion	**PER of InASR** (in %) ↓					
SNR(in dB)	−5	0	5	10	15	Avg.
Noisy	74.61	62.75	47.35	36.71	29.72	50.23
MSE-M	74.45	61.89	47.23	37.01	29.82	50.08
SISNR	72.04	60.42	47.50	36.38	29.33	49.13
CEGM	72.71	58.85	43.93	33.41	28.35	47.25

B. Back-end Acoustic Model

In [31], we use a hybrid DNN-HMM ASR model as the back-end, which is trained on the same TcdTimit-Noisy training set as the SE model. The back-end model consists of an acoustic model with the same structure as [35] and a 2-gram phone-based language model, denoted as InASR.

We then evaluate the enhanced speech using a real-world speech recognition application, denoted as RealASR. The RealASR model is also a hybrid DNN-HMM ASR model, consisting of an acoustic model, a language model, and a pronunciation dictionary. The acoustic model comprises 20 ResBlocks followed by a 12-layer variant of Transformer [36], where two ResBlocks follow each Multi-Head Attention. The ResBlock has a structure similar to the basic block in [37], but with a minor change where the Leaky ReLU activation replaces the ReLU activation. We use over 100,000 hours of Mandarin data collected in real scenarios to train the acoustic model. We adopt a 4-gram word-based language model trained with more than 500 million sentences and a large pronunciation dictionary containing over 600,000 Chinese words for decoding.

C. Evaluation Metrics

In this study, we evaluate the SE models in two ways: perceptual quality and recognition performance. Perceptual quality is assessed using the Perceptual Evaluation of Speech Quality (PESQ) [38] and Short-Time Objective Intelligibility (STOI) [39] metrics. PESQ is a speech quality estimator that predicts the mean opinion score of a speech quality listening test under certain degradations. The PESQ score ranges from -0.5 to 4.5, with a higher score indicating better speech quality. STOI measures speech intelligibility, with scores typically ranging from 0 to 1, where higher scores indicate better intelligibility.

Recognition performance is evaluated using the phone error rate (PER) and character error rate (CER) metrics. Lower PER and CER values indicate better recognition performance.

D. Recognition Performance Degradation for Real-World ASR Back-end

We first evaluated the recognition performance of SE models optimized by MSEM, SISNR and CEGM with InASR. All SE models were trained using the TcdTimit-Noisy training set, and the results are shown in Table 1. We found that

Table 2
AVERAGE CER COMPARISON OF SE MODELS TRAINED WITH DIFFERENT CRITERIA ON THE MANDARIN-NOISY TEST SET AT DIFFERENT SNRS.

Criterion	**CER of RealASR** (in %) ↓					
SNR(in dB)	−5	0	5	10	15	Avg.
Noisy	30.21	15.58	8.57	6.00	4.87	13.05
MSE-M	31.07	14.58	8.03	5.66	4.57	12.78
SISNR	30.93	14.64	7.89	5.77	4.88	12.82
CEGM	32.38	19.16	9.87	7.50	6.11	15.00
CML	22.02	11.28	6.25	4.82	4.39	9.75
w/o PCC	24.37	12.72	6.58	5.02	4.55	10.64
w/o CEGM	28.73	14.06	6.87	5.17	4.76	11.92
w/o SISNR	25.13	14.24	6.67	5.00	4.58	11.12
w/o MSE-M	24.92	14.22	6.57	5.01	4.56	11.06

CEGM outperformed MSEM and SISNR in PER across all SNR levels. Previous work [31] suggested that reducing distortions in the high-level representations extracted from low-level acoustic features by the back-end ASR model improves ASR performance.

We then used RealASR to evaluate the recognition performance of the same set of SE models. Results are shown in Table 2. MSEM and SISNR showed minimal performance improvements over unprocessed speech ("Noisy") at most SNR levels, with a performance degradation at −5 dB. This observation is consistent with previous studies [29], [31], indicating that the MMSE-based loss function directly improves perceptual quality rather than the back-end ASR performance. CEGM also yielded higher CER values than Noisy at all SNRs, suggesting that using CEGM to optimize SE models under high-performance acoustic models is challenging.

In contrast to the CEGM criterion, CML estimates a magnitude mask rather than the desired acoustic features of the back-end ASR model. The unbounded property of the acoustic feature makes it often difficult to optimize due to the large search space. On the other hand, the value of each bin in the mask ranges from 0 to 1. Two supervisions from low-level acoustic features (magnitude masks and reconstructed waveforms) can effectively avoid over-fitting acoustic knowledge from the back-end being passed to the SE model. Coupled with the active modeling of the correlation between distortions on low-level and high-level features, the whole optimization difficulties have been significantly reduced. In contrast to the CEGM criterion, the CML approach estimates a magnitude mask rather than the desired acoustic features of the back-end ASR model. This is beneficial as the unbounded property of acoustic features often makes optimization challenging due to the large search space. In comparison, the value of each bin in the mask ranges from 0 to 1, making optimization more feasible. Furthermore, the use of two supervisions from low-level acoustic features, namely magnitude masks and reconstructed waveforms, effectively prevents over-fitting of acoustic knowledge from the back-end being passed to the SE model. Additionally, the active modeling of the correlation between distortions on low-level and high-level features significantly reduces the overall optimization difficulties. Our

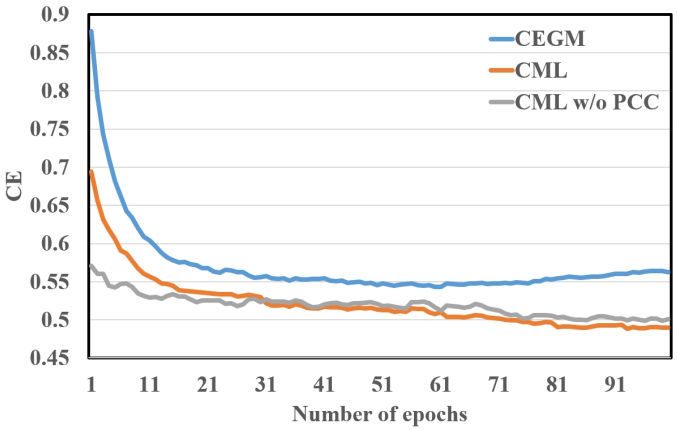

Fig. 2. A comparison of learning curves between CEGM and CML.

experimental results in Table 2 show that CML yielded more improvements when compared to MSEM, SISNR, and CEGM at all SNRs, especially at lower SNRs.

E. Ablation Study

We conducted an ablation study, as presented in Table 2, to analyze the contribution of each loss item to the overall performance. Our results show that each loss item significantly contributed to the performance improvement. Specifically, removing PCC, CEGM, SISNR, and MSE-M resulted in a relative increase in CER by 9.19%, 22.21%, 14.06%, and 13.36%, respectively. These findings demonstrate the importance of leveraging multiple loss functions through our proposed CML approach to achieve the best possible outcome.

To evaluate the optimization performance of our proposed method, we compared the learning curves of the cross-entropy (CE) between CEGM and CML on the validation set, as shown in Fig. 2. We observed that the learning curve of CEGM started to rise after the 66-th epoch, whereas the learning curve of CML continued to decline and consistently generated smaller CEs on the validation set than CEGM. Notably, when we removed PCC from the CML loss function, the learning curve converged to a higher CE value earlier, indicating the importance of explicitly modeling the interplay between different loss functions in optimizing the SE model.

F. Perceptual Quality Evaluation

To evaluate the perceptual quality of the reconstructed speech, we compared the average PESQ and STOI scores among the four different enhancement methods (Noisy, MSE-M, SISNR, and CML) at different SNR levels. We plotted the results in Figure 3.

From the plot, we can observe that SISNR achieves a higher average STOI score compared to MSE-M (79.02% vs. 78.02%), while the reciprocal results are observed for PESQ (2.53 vs. 2.56). This suggests that MSE-M is better at preserving the original speech signal's perceptual quality, while SISNR is better at improving intelligibility.

Furthermore, the complementarity of the methods is also reflected in their performance across different SNR levels. Specifically, SISNR performs better than MSE-M at low SNRs

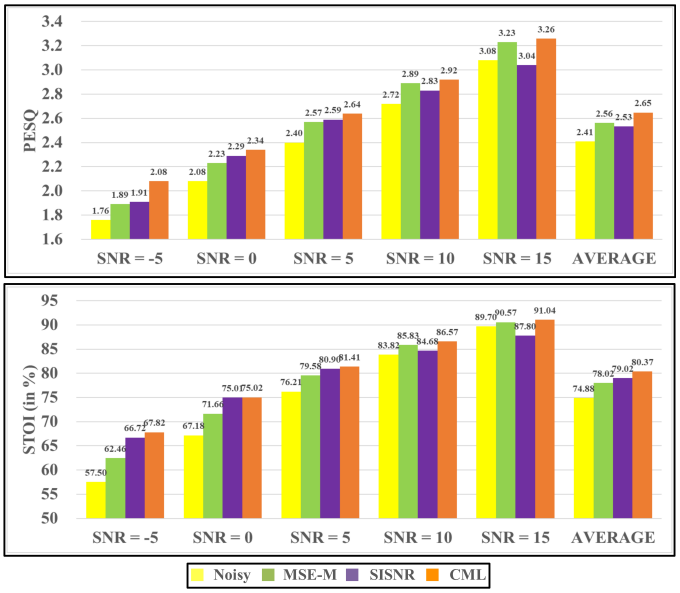

Fig. 3. PESQ and STOI comparisons of SE models trained with different criteria on the Mandarin-Noisy test set at different SNRs.

(-5 and 0 dBs) across both PESQ and STOI metrics, while reciprocal results are observed at high SNRs (10 and 15 dBs). This indicates that SISNR is better suited for improving the perceptual quality of speech signals with a high level of noise, while MSE-M is more effective at improving the quality of speech signals with low to moderate noise levels.

Finally, the CML method takes advantage of the complementarity of MSE-M and SISNR and achieves the best performance across both PESQ and STOI metrics at all SNR levels. This suggests that combining the two methods can improve the overall quality of the reconstructed speech signals, regardless of the noise level.

IV. Conclusion

This paper proposed a novel correlated multi-level (CML) optimization approach for speech enhancement, which addresses the challenge of optimizing SE models with high-performance back-end ASR models. By leveraging multiple loss functions that model distortions on different representations and explicitly modeling their interplay, the proposed CML approach significantly improves the recognition performance and perceptual quality of the enhanced speech. Our empirical results demonstrate the effectiveness of CML in the context of a high-performance acoustic model from a real-world application. Future work could focus on exploring network structures to reduce complexity and enable real-time operations on low-power portable devices. In addition, extending the proposed CML approach to handle other types of distortions, such as reverberation, would be an interesting direction for future research.

***Abstract*—Audio-visual speaker diarization (AVSD) is a critical technique that segments audio-visual signals and assigns them to multiple speakers in practical scenarios. Thus, how to efficiently extract the cross-modal information from audio-visual signals is essential for AVSD. In this paper, we present CASA-Net, an embedding fusion method for end-to-end AVSD system. CASA-Net incorporates cross-attention (CA) module to capture cross-modal information in audio-visual signals, and utilizes self-attention (SA) module to learn the context information among audio-visual frames. On the development set of the Multimodal Information Based Speech Processing (MISP) Challenge 2022, the proposed CASA-Net achieved a diarization error rate (DER) of 13.18%, which is 1.56% lower compared to the concatenation (Concat) method. To further enhance performance, we utilized beamforming to integrate the available multi-channel audio information, along with data augmentation. By fusing multiple systems, we ultimately achieved a DER of 12.60% on the development set.**

I. Introduction

Audio-only speaker diarization segments and classifies a speech signal from multiple speakers, which assigns different parts of the signal to different speakers. This process can be viewed as a technique for speech signal separation and clustering, which solves the problem of "who spoke when" and is essential for practical scenarios such as audio conferences, conversations and interviews [1][2]. Several systems [3][4] provides feasible solutions for the audio-only speaker diarization.

The discovery that visual cues can aid in human speech perception [5] has sparked interest in exploring video information [6]–[9] to improve the challenge of audio-only speaker diarization. The Multimodal Information Based Speech Processing (MISP) Committee has released the first large-scale multi-microphone conversational Chinese audio-visual corpus [10]. Additionally, the MISP 2022 Challenge introduced the track1 challenge, specifically focusing on addressing the Audio-Visual Speaker Diarization (AVSD) task by labeling speech timestamps according to the identify of speakers. This challenge aims to encourage participants to leverage audio and visual information and explore the fusion technology of multiple modalities to enhance the AVSD system's robustness in complex scenarios.

The study conducted by [8] reveals that Visual Voice Activity Detection (V-VAD) is more adept at handling overlapped speech segments than audio-only speaker diarization within the MISP corpus. V-VAD is an advanced technology that utilizes visual information to detect voice activity. Its objective is to determine the presence, absence, or temporal boundaries of speech activities by analyzing facial expressions, lip movements, and other visual features in video images [11][12]. Simultaneously utilizing temporal context information [13][14] in videos is beneficial to learn visual representations. However, the effectiveness of V-VAD can be compromised when visual features are absent due to occlusions and off-screen speakers. Additionally, the observation of lip movements can be impeded by the speaker's head movements and environmental factors, whereas the audio remains unaffected. Therefore, it is crucial to explore methods that capture the correlation between audio and lip movements, as well as the context information from audio-visual frames, to enhance the performance of audio-visual speaker diarization.

Motivated by the attention mechanism for active speaker detection(ASD) [15] and context information extraction [16], we proposed our Audio-visual speaker diarization system for the MISP 2022 track1 challenge. We utilized the outputs of the audio and visual modality encoders as inputs to the Cross-Attention (CA) module to capture cross-modal information, and then used Self-Attention (SA) module to learn context relationships between temporal frames. As the MISP corpus employs multi-channel recording equipment, we employed beamforming to integrate multi-channel far-field audio to enhance robustness. Furthermore, to address audio noise and lip image interference, we applied various data augmentation techniques such as external audio noise and image transformations during the training process. We presented the results based on the publicly accessible development set. With CASA-Net, we achieved a diarization error rate (DER) of 13.18% on the development set, with a 1.56% reduction compared to the Concat method. Subsequently, our performance was further improved by beamforming and data augmentation. Finally, using DOVER-lap [17] to fuse our three systems, we obtained a DER result of 12.60%.

The following sections of our paper will be organized as follows: In Section 2, we introduce some related works of the baseline, including encoders, extractor and decoder. Section 3 describes the proposed network framework and optimization. In Section 4, we demonstrate the experimental setup and analyze the results, respectively. The Section 5 concludes the research.

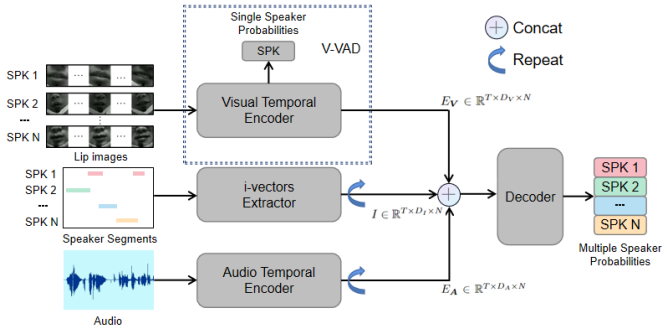

Fig. 1. The baseline [8] of MISP 2022 Challenge.

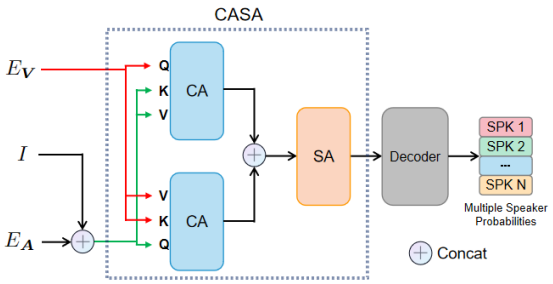

Fig. 2. The framework of CASA network.

II. Related Works

The MISP 2022 Challenge adopts [8] as the baseline, which includes multiple modules: visual and audio temporal encoders, *i-vector* extractor and decoder. Fig. 1 shows its structure.

A. Visual temporal encoder

The visual temporal encoder functions as visual voice activity detection (V-VAD). We cut the video into multiple blocks, and the lip images within each block are served as inputs $X_{\boldsymbol{V}} \in \mathbb{R}^{T\times W\times H\times N}$ to visual temporal encoder. Then we obtained the visual embedding outputs as $E_{\boldsymbol{V}} \in \mathbb{R}^{T\times D_V\times N}$, where T is the total number of frames, W and H are the width and height of image, D is the dimension, and N is the number of speakers.

B. Audio temporal encoder

We used the FBANKs as inputs for the audio temporal encoder, utilizing four-layer CNNs that consist of 2D Convolution, BatchNorm and ReLU for each layer. Then we got the outputs $\hat{E}_{\boldsymbol{A}} \in \mathbb{R}^{T\times D_A}$ through a fully connected layer. Finally, we repeated N times to obtain $E_{\boldsymbol{A}} \in \mathbb{R}^{T\times D_A\times N}$ to align with $E_{\boldsymbol{V}}$.

C. I-vector extractor

In [8], *i-vector* is claimed to solve alignment problems when lips are missing due to occluded cameras or unreliable lip detection. We use a 100-dimensional *i-vector* extractor trained on CN-Celeb [18] to obtain speaker embeddings. These *i-vectors* are computed using oracle labels (provided by the MISP organizing committee) for each speaker. The outputs $\hat{I} \in \mathbb{R}^{D_I\times N}$ is repeated T times to get $I \in \mathbb{R}^{T\times D_I\times N}$ to align with $E_{\boldsymbol{V}}$.

D. Decoder

The structure of the decoder is similar to [4], where it concatenates all embeddings as inputs $E_{\boldsymbol{all}} \in \mathbb{R}^{T\times(D_A+D_V+D_I)\times N}$ and the outputs of prediction is $S \in \mathbb{R}^{T\times N}$. In addition, a softmax operation is adopted to calculate the loss between the outputs and the labels.

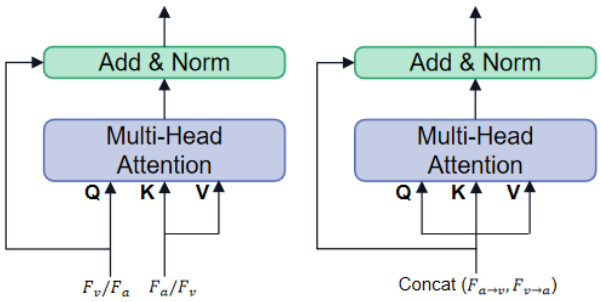
III. Proposed Methods

Fig. 2 shows our CASA network structure. The lip images, *i-vectors*, and audio data are input into visual temporal encoder, *i-vector* extractor and audio temporal encoder to obtain the corresponding embeddings. As both *i-vector* and audio are closely associated with the audio modality, we concatenated them as complementary sources. Instead of using the Concat method in [8], we propose the CASA network, which is composed of cross-attention (CA) module and self-attention (SA) module to learn the intrinsic cross-modal information from the embeddings.

A. Cross-Attention (CA)

Although it is impossible to fully align the time of audio-visual data, we hope to learn audio-visual instantaneous interactive information at the frame level through cross-attention. Audio and visual representations are inputs for query (Q), key (K) and value (V) for audio-visual interaction.

Since both $E_{\boldsymbol{A}}$ and I are generated from audio data, we concatenate them as $F_a \in \mathbb{R}^{T\times(D_A+D_I)\times N}$, while $E_{\boldsymbol{V}}$ is equivalent to $F_v \in \mathbb{R}^{T\times D_V\times N}$. The multi-head attention mechanism allows the model to focus on different aspects of useful information and extract richer features. As formulated in Eq. (1) and Eq. (2), the query is generated by F_v, and the key and value are generated by F_a for $F_{a\to v} \in \mathbb{R}^{T\times D_V\times N}$, and vice versa. The left side of Fig. 3 shows the detailed structure of the $F_{a\to v}/F_{v\to a}$.



$$F_{a\to v} = \text{softmax}\left(\frac{Q_v K_a^T}{\sqrt{d}}\right) V_a \tag{1}$$

$$F_{v\to a} = \text{softmax}\left(\frac{Q_a K_v^T}{\sqrt{d}}\right) V_v \tag{2}$$

B. Self-Attention (SA)

Self-attention module can learn the context relationship between temporal audio-visual frames and increase their correlation..

The Fig. 3(b) shows the detailed structure of the SA module. The query, key and value are all generated by the concatenation of $F_{a\to v}$ and $F_{v\to a}$.

(a) Cross-Attention (CA) (b) Self-Attention (SA)

Fig. 3. Structure of CA and SA

C. Optimization

We proceeded a two-step training strategy.

- **Step 1.** Train a V-VAD model (Visual Temporal Encoder) using lip images. The loss function is presented in Eq. (3), where $BCE()$ is the binary cross entropy (BCE) loss function [19], $S^V_{t,n}$ and $Y_{t,n}$ are the predicted and the ground truth labels of person n in the t^{th} video frame, T refers to the number of video frames, and N is the number of people in the scenario.

$$Loss_V = \frac{1}{NT}\sum_{n=1}^{N}\sum_{t=1}^{T} BCE\left(Y_{t,n}, S^V_{t,n}\right) \quad (3)$$

- **Step 2.** Freeze the V-VAD network for extracting visual features, align visual features and audio data frames, then train the audio temporal encoder, CASA network and the decoder. The loss function is presented in Eq. (4), where $S^{AV}_{t,n}$ is the predicted labels of person n in the t^{th} audio-visual frame.

$$Loss_{AV} = \frac{1}{NT}\sum_{n=1}^{N}\sum_{t=1}^{T} BCE\left(Y_{t,n}, S^{AV}_{t,n}\right) \quad (4)$$

IV. Experiments and Result

A. Dataset and metrics

Dataset. The MISP 2022 Challenge dataset [10] includes more than 100 hours of audio-visual data, from 320+ sessions. Each session consists of about 20 minutes of discussion. The dataset has been split into training (Train), development (Dev) and evaluation sets. The evaluation dataset is not publicly released, so we only discussed the results on the development set. The information of Train and Dev sets as show in Table I.

TABLE I
The MISP 2022 challenge dataset

Dataset	Train	Dev
duration(h)	106.09	2.60
Session	301	10

The dataset faces several technical challenges. Firstly, the dataset exhibits a high speech overlap rate, particularly when two groups of speakers are present, with an overlap rate of up to 70%. Secondly, reverberation negatively impacts the audio quality, and TV noise interference can be misclassified as the audio of the target speaker. Additionally, a fixed microphone array is used as the recording device in this scenario, to provide multi-channel signals that increase the difficulty. For the training set, the released videos include far and middle scenes, while audio includes far, middle and near scenes. But for Dev set, there are only video and audio from far scenes. There is no intersection between datasets.

We used the training set to train our all experiments and it included audio signal and lip images. We dereverberated the raw audio signal with NARA-WPE [20] and utilized beamforming technology in Kaldi[21] toolkit to effectively use multi-channel audio information, then applied additive noises (i.e., Babble, Noise, and Music from Musan [22]) and RIRs corpora as the audio augmentation. For audio signals, we got a total 11-fold training dataset, including multi-channel data (6 folds), beamforming (1 fold) and additive noises for beamforming (4 folds). To augment the lip images, we applied random cropping, rotation, flipping, and brightness adjustments. In addition, we extracted non-spoken lip videos from the training set's RTTM (Reference Time and Text Markup) to fill empty lip videos within consecutive temporal audio-visual frames and empty speakers, because each scene has a fixed input of speaker number, so may exist empty speaker inputs, it makes the system to have the ability to distinguish between valid and invalid inputs.

Metrics. We measure the performance of our model by Diarization Error Rate (DER) [23], which is represented with Eq. (5).

$$DER = \frac{FA + MISS + SpkErr}{TOTAL} \quad (5)$$

where FA is the speech durations of false alarm, $MISS$ is the speech durations of missed detection, $SpkErr$ is the speech durations of speaker error, and $TOTAL$ is the sum of durations of all reference speakers' utterances.

B. Implementation details

1) Training: We fixed 6 speakers as input from one scene. The training audio and video signals are segmented into 8-second data blocks with a 4-second step. For the audio input, we used 40-dimensional FBanks as the acoustic feature, with a frame length of 25 ms and a frame shift of 10 ms, and each block has 800 audio frames. In the video modality, lip region images with a resolution of 96×96 and an FPS (Frames Per Second) of 25 are utilized, and each block has 200 visual frames.

Initially, the V-VAD model is trained using BCE loss and the Adam optimizer, with a learning rate of 1e-4, then the video features are extracted through the freezed V-VAD model for each frame and serve as input for the video modality. In the second step, the audio modality input is combined and passed through CASA and decoder modules. BCE loss and the Adam optimizer are employed, with a learning rate of 1e-4 until convergence.

TABLE II
THE PERFORMANCE OF DIFFERENT SYSTEMS ON THE MISP 2022 DEVELOPMENT SET.

NO	Modality	System	Fusion Method	Lip_aug	Beamforming	Audio_aug	MISP_2022_DEV			
							FA(%)	MISS(%)	SpkErr(%)	DER(%)
1	Visual	Baseline	-	×	-	-	6.64	8.17	3.89	18.69
2		Baseline_aug	-	✓	-	-	6.67	7.65	3.65	17.97
3	Audio-visual	Baseline	Concat(Joint training)	×	×	×	4.01	5.86	3.22	13.09
4		Ours	Concat	✓	×	×	3.44	6.53	4.77	14.74
5			CASA	✓	×	×	2.61	6.85	3.72	13.18
6				✓	✓	×	2.43	6.72	3.68	12.83
7				✓	✓	✓	2.39	**6.62**	**3.62**	12.63
8	Fusion	DOVER-Lap of NO.5, 6 and 7	-	-	-	-	**2.32**	6.63	3.65	**12.60**

2) Evaluation: All development sets were divided into 8-second blocks with a step of 6 seconds, and the scores of the overlapped parts between the blocks are averaged as the result. And the competition provided the Oracle VAD and allowed participants to use it.

C. Results

Table II illustrates the DERs (%) comparison of our systems and the baseline. System 1 and 3 are the official baselines in Visual-only and Audio-visual modality respectively. We made lip images augmentation based on System 1 to obtain System 2, Baseline_aug. System 4 is our reconstitution on System 3 without joint training. System 5-7 are our proposed structures with CASA using different data augmentation methods.

Compared to the Visual-only systems, all Audio-visual systems can effectively integrate audio-visual information, and achieve improved performances with lower DERs. The results of Systems 1 and 2 show that effective lip images augmentation can simulate more complex real scenarios and enhance the ability of V-VAD to detect speech and silence. We observe that the CASA fusion method in System 5 achieved a DER of 1.56% improvement compared to System 4, which indicates that CASA can capture more cross-modal interaction information and learn the context relationship between temporal audio-visual frames than the Concat method. Furthermore, the performance of System 6 shows that beamforming effectively utilizes multi-channel speech information, and surpasses that of System 3. Additionally, the audio augmentation in System 7 obtained a better DER of 12.63% based on the results of System 6. Finally, by employing DOVER-lap for fusing our multiple systems, we achieved a DER of 12.60%.

V. CONCLUSION

This paper introduces an embedding fusion method incorporating cross-attention and self-attention mechanisms for audio-visual speaker diarization. Our two-step approach enables the training and integration of both audio and visual modalities, leveraging V-VAD and CASA to enhance system performance and optimization. We have made a series of improvement measures, including beamforming, data augmentation and system-fusion technology, to address the current difficulties faced by AVSD. Finally, our system achieved DER of 12.60%, surpassing the baseline. This result highlights the effectiveness of our approach. We did not conduct joint training in this paper, which will be our future research work.

***Abstract*—Recently, deep learning-based beamforming algorithms have shown promising performance in target speech extraction tasks. However, most systems do not fully utilize spatial information. In this paper, we propose a target speech extraction network that utilizes spatial information to enhance the performance of neural beamformer. To achieve this, we first use the UNet-TCN structure to model input features and improve the estimation accuracy of the speech pre-separation module by avoiding information loss caused by direct dimensionality reduction in other models. Furthermore, we introduce a multi-head cross-attention mechanism that enhances the neural beamformer's perception of spatial information by making full use of the spatial information received by the array. Experimental results demonstrate that our approach, which incorporates a more reasonable target mask estimation network and a spatial information-based cross-attention mechanism into the neural beamformer, effectively improves speech separation performance.**

I. Introduction

The target speech extraction task is derived from the speech separation task, which aims to extract the speech of a specific target speaker from a mixed signal. Unlike conventional speech separation, which deals with the permutation order of signals, target speech extraction only focuses on extracting the target signal, thus avoiding the permutation problem [1]. In recent years, multi-channel beamforming algorithms have shown great potential in the task of target speech extraction. Beamforming algorithms achieve spatial domain filtering of the observed signal by enhancing the signal in the desired direction and suppressing the signal in other directions, which naturally meets the task goal of target speech extraction. Classical beamforming algorithms require accurate estimation of the wave direction and determination of the speech or noise part in the mixed signal [2], which is difficult to obtain in noisy and reverberant environments using traditional algorithms. Therefore, obtaining accurate target orientation information in real scenes, improving the estimation accuracy of the covariance matrix, and solving the numerical instability problem in matrix operations are the key to improving beamforming performance.

In recent years, the development of deep learning technology has provided new research ideas for solving the above problems. First, using neural networks for wave direction estimation has achieved good experimental results [3], providing more accurate target orientation information for beamforming algorithms. At the same time, combining neural networks with beamforming algorithms improves the estimation accuracy of the covariance matrix and effectively improves the performance upper limit of beamforming algorithms. Among them, Mask Based Beamforming, as a classic representative of the combination of deep learning and beamforming algorithms, uses a neural network to predict the mask of speech and noise to calculate the spatial covariance matrix of speech and noise, respectively, and then inputs it into traditional beamforming algorithms such as GEV or MVDR for numerical calculation [4], [5]. For the numerical instability problem that traditional beamforming algorithms still have difficulty in solving even after diagonal loading [6] in matrix numerical operations, ADL-MVDR [7] used an RNN to replace the matrix inversion and eigendecomposition processes in the MVDR beamforming algorithm, avoided the numerical instability caused by singular matrices in matrix operations, and achieved significant performance improvement for the neural beamformer. In recent experiments, the combination of deep learning and beamforming algorithms has been further deepened. GRNNBF [8] used an RNN to model the covariance matrices of speech and noise, replaced all matrix numerical operations in traditional beamforming algorithms, and directly predicted beamforming weights using neural networks, achieved good separation results. SARNN [9] added self-attention mechanism to the beamforming module, enhanced the neural network's modeling ability for the spatial and temporal information contained in the covariance matrix. EABNet [10] adopted a more aggressive approach, directly modelled the array observation signals to obtain higher-dimensional information representations than the covariance matrix. The neural network implicitly includes all the calculation steps of beamforming and directly outputs beamforming weights. The above methods combined with deep learning technology have all achieved good performance improvements for beamforming algorithms.

In scenarios such as in-car and remote conferences, the position of the target speaker relative to the microphone array is often fixed, and its angle information is easily obtained through the device [1]. To leverage the angle information of the target sound source, Chen et al. proposed the wave direction feature calculated using the angle information of the target sound source, which enhanced the directionality of the speech separation system [11]. ADL-MVDR [7], GRNNBF [8], SARNN [9], UFE [12], etc. inputted the angle feature

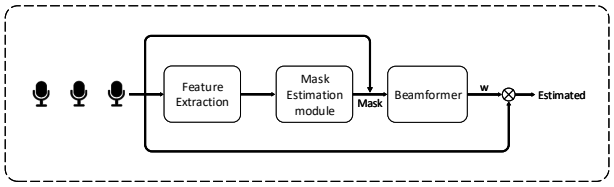

Fig. 1. General structure of a neural beamformer.

into the neural network, improved the separation module's perception of spatial information, thereby improved the separation performance of the system. Gu et al. extended the angle feature from a two-dimensional plane to a three-dimensional space, improved the separation performance of the model when the azimuth angle between the target sound source and the interference source was small [13].

In this paper, we designed a model that uses target spatial orientation information to enhance the performance of neural beamforming. The system consists of a front-end pre-separation module and a back-end beamforming module. Compared with other models, our improvements mainly focus on the following two points:

• To improve the estimation accuracy of the spatial covariance matrices of speech and noise, we stack the input features in the channel dimension and use the UNet-TCN structure to model the input features. This avoids the loss of feature information caused by directly reducing the input features after connecting them in the frequency dimension.

• To better utilize the spatial information obtained by the array, we transform the spatial features of the input signal and the covariance matrix calculated by the pre-separation module into a feature space with the same dimensionality. We then use a cross-attention mechanism to enhance the beamforming network's perception of spatial orientation, thereby improving the prediction accuracy of the beamforming weights.

Experimental results show that after the improvements to the pre-separation module and beamforming module mentioned above, the target speech separation performance of the neural beamformer could be effectively improved.

The remainder of this paper is organized as follows. Section II presents the signal model for the target speech extraction task and the beamforming algorithm. Section III details our proposed neural beamforming algorithm. Section IV provides an overview of the experimental setup and presents an analysis of the experimental results. Finally, Section V concludes the paper.

II. Signal Modeling and Beamforming

Consider the far-field time-domain signal model of the real scene, described as:

$$y(t) = x(t) * a_1(t) + n(t) * a_2(t) + s(t) \quad (1)$$

$$= x^{'}(t) + n^{'}(t) + s(t) \quad (2)$$

where $y(t) = [y^{(0)}(t), y^{(1)}(t), ..., y^{(M-1)}(t)]^T$ indicating the time-domain signal received by the M-channel microphone array. $x(t), n(t)$ represent the reverberation-free speech signals from the target speaker and the interfering speaker, respectively. $a_1(t), a_2(t)$ are the room impulse response(RIR) between the speaker and the array elements of the microphone. $*$ denotes the convolution operation. $x^{'}(t), n^{'}(t)$ represent the speech signals of the target speaker and the interfering speaker with reverberation, respectively. $s(t)$ is the background noise. When not focusing on the dereverberation task, the task goal of target speech extraction is to extract the target speaker's speech $x^{'}(t)$ from the noisy signal $y(t)$.

After the signal model is transferred to the time-frequency domain by short-time fourier transform(STFT), it is expressed as:

$$Y(t,f) = X(t,f) + N(t,f) + S(t,f) \quad (3)$$

The purpose of the beamforming algorithm is to obtain the filter weight w for the array observation signal, and extract the desired signal from the array observation signal by performing spatial filtering on the observation signal, that is:

$$X(t,f) = w^H Y(t,f) \quad (4)$$

where $(\cdot)^H$ denotes the conjugate transpose operation.

Taking the traditional MVDR beamforming algorithm as an example, the purpose is to minimize the output noise power of the beamforming algorithm without distorting the signal, that is:

$$min(w^H \Phi_{NN} w^H), \quad s.t \quad w^H \alpha(\theta) = 1 \quad (5)$$

For the above formula, the desired filter weight w is solved by the lagrange multiplier method:

$$w = \frac{\Phi_{NN}^{-1}\alpha(\theta)}{\alpha^H(\theta)\Phi_{NN}^{-1}\alpha(\theta)} \quad (6)$$

where $\Phi_{NN} = N(t,f)N^H(t,f), \Phi_{NN} \in M \times M$ is the covariance matrix of the noise signal, $\alpha(\theta) = [e^{-j\omega\tau_m}], m = [0, 1, ..., M-1]$ is the steering vector that calculated using target sound source's DOA. When the steering vector is difficult to obtain due to the interference of environmental factors, PCA can be performed on the covariance matrix of the speech signal to obtain the estimated value of the steering vector [14].

Therefore, it can be seen that the key to the beamforming algorithm lies in the estimation of the covariance matrix. Traditional beamforming methods often rely on certain algorithms to determine the time periods of speech and noise in the signal, but these approach is not optimal. With the development of deep learning technology, using deep neural networks to determine the speech and noise components in the signal has achieved good experimental results.

Fig. 1 shows the general framework of the combination of neural network and beamforming. It first predicts a set of time-frequency masks representing the corresponding relationship between the desired signal and the original mixed signal through the neural network, such as IBM [4], IRM [5], CRM [15], CRF [16], etc. Taking the IRM as an example, it defines

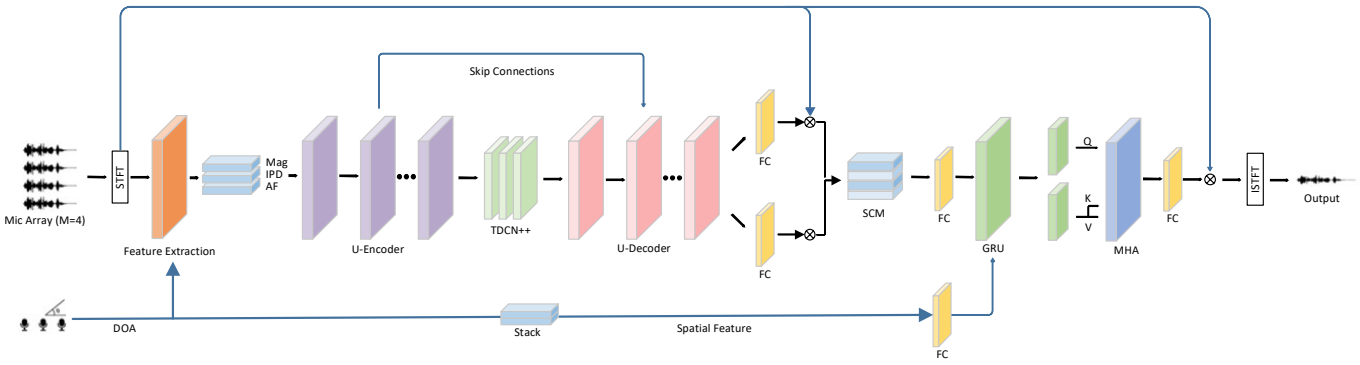

Fig. 2. The overall structure of our proposed model.
Both the input features and the covariance matrix are stacked along the channel dimension when inputting to the network.

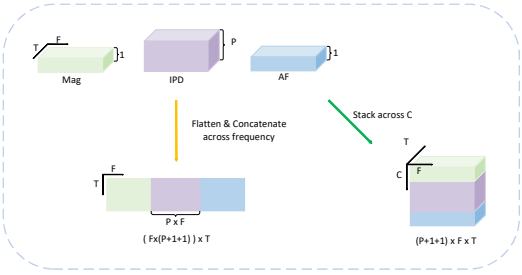

Fig. 3. The combination of input features.

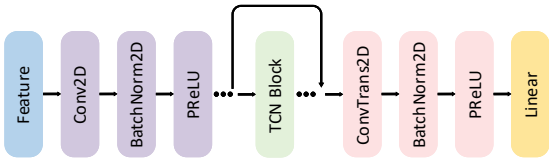

Fig. 4. Pre-separator based UNet-TCN structure

the energy ratio relationship between the desired signal and the mixed signal:

$$IRM_x = \frac{|X(t,f)|}{|Y(t,f)|} \tag{7}$$

Then the speech and noise components in the mixed signal can be recovered through mask, so as to calculate the speech and noise space covariance matrix respectively [4]:

$$\Phi = \frac{\sum_{t=1}^{T} M^2(t,f) Y(t,f) Y^H(t,f)}{\sum_{t=1}^{T} M^2(t,f)} \tag{8}$$

Once the covariance matrix of the target signal and noise is calculated, it can be substituted into traditional beamforming algorithms such as GEV and MVDR to obtain the beamforming weight w. Recent experiments have demonstrated that utilizing neural networks to model covariance matrix information and predict beam weights can lead to improved target speech separation compared to traditional algorithms.

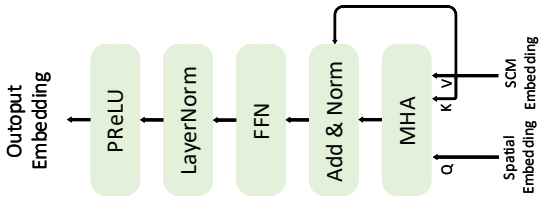

Fig. 5. A cross attention module with spatial information as Query and covariance matrix information as Key and Value. All features are on the time frame level.

III. Enhanced Neural Beamformer with Spatial Information

Fig. 2 shows the overall architecture of our proposed model. First, the observation signal of the array is transformed into the time-frequency domain by STFT to extract the spatial features of the signal. The pre-separation network then estimates the mask of the target speech and noise based on the input features and calculates the covariance matrix. Following this, the beamforming network leverages the spatial features to predict the beamforming weight, which is subsequently used to beamform the observed signal. Finally, the original time domain signal is restored through ISTFT. Specifically as follows:

A. Feature Extraction

The first microphone from the multi-channel mixed signal is selected as the reference microphone, and its received signal's amplitude spectrum is calculated as the input feature for the pre-separation network.

$$Y_1^{mag}(t,f) = |Y_1(t,f)| \tag{9}$$

To obtain the spatial information of the microphone array, we select P pairs of microphones and calculate the phase difference between each pair as the spatial feature for the input of our model. This approach has been widely used in speech enhancement and source separation tasks, as it provides a concise and effective way to capture the spatial information of the microphone array.

$$IPD_{i,j}(t,f) = \angle Y_i(t,f) - \angle Y_j(t,f) \tag{10}$$

$$i, j \in (0, 1, ..., M-1), i \neq j$$

In order to enhance the spatial information acquired by the model, the cosine distance between the phase delay φ_1 of the signal in the desired direction on the array and the phase difference φ_2 observed by a certain pair of microphones is calculated. Then sum over all P pairs of microphones. That is, the angular characteristics of the target signal serve as supplementary input.

$$AF(\theta, f) = \sum_{p=1}^{P} cos(IPD_{i,j}(t, f) - \frac{2\pi f d cos\theta}{c}) \quad (11)$$

When the phase angle of the mixed signal and the desired signal is closer, the value of the angle characteristic tends to 1 approximately [12]. All these features are stacked along the channel dimension to serve as the network's input features.

$$Feature = [Y_1^{mag}(t, f), cosIPD_{i,j}(t, f), AF(\theta, f)]$$

B. Pre-separation Module

The pre-separation network adopts an Encoder-TCN-Decoder structure, which includes 2D convolutional layers, linear layers, and a variant of TCN [17]. To process the input features, it's a common practice to concatenate them on the frequency dimension, followed by 1D convolution to reduce dimensionality before feeding them into the TCN or RNN module [7], [8], [9]. However, to avoid the loss of feature information due to direct dimensionality reduction of the input features, we employ the UNet-TCN structure to model them. By stacking the input features along the channel dimension, we obtain $Y_{input} \in R^{N \times F \times T}(N = P + 1 + 1)$, which is then fed into the UNet-TCN layer to model the nonlinear mapping of the time dimension from the source signal domain to the separated signal domain and noise domain. Finally, the predicted cRM is restored through the linear layer to recover the target speech.

$$X_{cRM}(t, f) = (cRM_r + jcRM_i)(Y_r + jY_i) \quad (12)$$

The noise signal is also calculated in the above way. All activation functions in the pre-separation network use PReLU to accelerate the convergence speed of the network. Compared with ReLU, it allows negative values to appear, which is synergistic with the negative values between the input phase difference and the output mask.

C. Neural Beamforming Module

The beamforming network is composed of a recurrent neural network and a cross-attention module. First, the speech and noise signals generated by the pre-separation of the front-end network are used to calculate the spatial covariance matrix $\Phi_{SS}(t, f) \in C^{M \times M}, \Phi_{NN}(t, f) \in C^{M \times M}$ at the time frame level respectively.

$$\Phi_{SS}(t, f) = X_{cRM}(t, f) X_{cRM}^H(t, f) \quad (13)$$

$$\Phi_{NN}(t, f) = N_{cRM}(t, f) N_{cRM}^H(t, f) \quad (14)$$

Since the spatial covariance matrix is a complex-valued Hermitian matrix, and the defined neural network is a real network, the real and imaginary parts of the speech and noise signal covariance matrices are concatenated on the channel dimension, and LayerNorm is used to the covariance matrix of is standardized. In order to enhance the spatial constraints on the beamformer, we use the spatial information received by the array, that is, the phase difference between channels and the angle characteristics of the target sound source, to perform a cross attention mechanism on the covariance matrix of speech and noise. First, the linear layer and GRU are used to transform the spliced covariance matrix and cosIPD, Angle-Feature(AF) to model the inter-channel information at the time frame level and transform it into embedding of the same dimension. Subsequently, the modeled spatial information is used as the query of multi-head attention, and the covariance matrix information is used as the key and value, and the spatial orientation information is used to enhance the ability of attention to model inter-channel information at the time frame level.

$$Query = RNN - DNN(cosIPD, AF) \quad (15)$$

$$Key, Value = RNN - DNN(\Phi_{SS}, \Phi_{NN}) \quad (16)$$

$$Attention(Q, K, V) = softmax(\frac{QK^T}{\sqrt{d_k}})V \quad (17)$$

Then, the observed signals from the microphones are beamformed using the beamforming weights output by the linear layer to obtain the spectrogram of the model prediction output. The time-domain signal is then recovered through ISTFT, resulting in the desired time-domain speech signal.

IV. Experiment setup and result analysis

A. Dataset settings

The source speech signals for the target and interfering speakers were obtained from the Aishell2 [18] dataset, while the background noise data was sourced from DNS2023 [19]. For an indoor reverberation scene, the room size was set to a random size between [3, 3, 1.5] and [8, 8, 2.5] meters for length, width, and height, and the reverberation time(rt60) was set to 0.1-0.6 seconds. The simulation was carried out using the image source method, generating room impulse responses for the target and interference signals [20]. The microphone array consisted of a four-element linear array with an element spacing of 3 cm. To ensure a certain degree of spatial independence in the signals, we set the minimum angle between the two sources relative to the microphone array to 5°. The signal-to-noise ratio between the target and interference signals was set to [-6, 6] db. To enhance the model's robustness, a background noise of [-5, 20] db was added to the simulated data. In total, the simulation generated 120,000 pieces of training set data, 14,000 pieces of validation set data, and 7,000 pieces of test set data. All audio was downsampled to 16kHz and each piece of data is 4 seconds long.

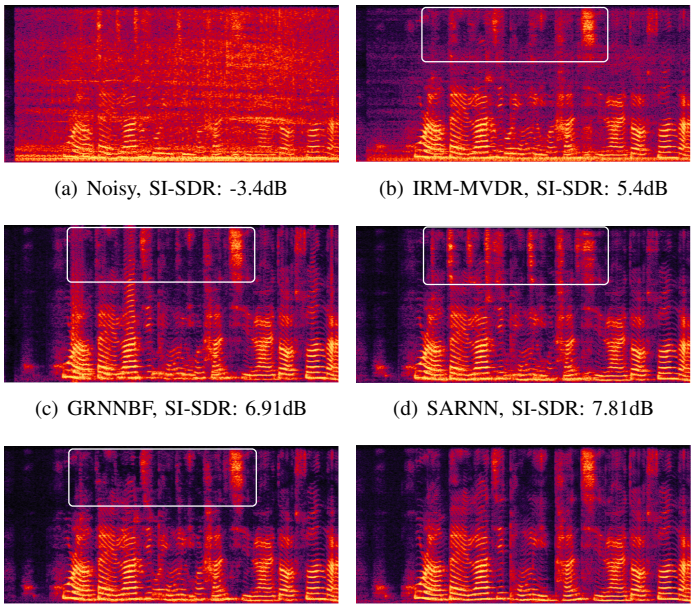
B. Experiment settings



During the training process, the window length of STFT and the number of FFT points are set to 32ms, and the frame shift is set to 16ms. For the array, we select (0,1), (0,2), (0,3) three microphone pairs to calculate cosIPD. Therefore, the channel dimension of the input feature is 5, that is $Feature \in R^{5\times F\times T}$. For the pre-separation module, the number of channels of Conv2D in the UNet structure is (5, 32, 64, 128). The TCN structure is a 3x8 stacked TCN Block with 128 channels. For the beamforming module, the number of hidden layer units of the double-layer GRU network is 256, the dimension of the cross attention module is 128, and the last linear layer outputs complex-valued beamforming weights, so the output dimension is set to 8 (channels*2), the proposed The model is trained end-to-end.

The experiment uses two A100 graphics cards to train 60 epochs on the simulation data set, and the Batch Size is set to 24. The Adam optimizer is used for optimization, the initial learning rate is set to 2e-3 and decays continuously with the number of epochs, and the decay coefficient is 0.98. The maximum gradient clipping is set to 10 to speed up the network convergence process.

We use the MVDR method based on the IRM and the GRNNBF [8] and SARNN[9] models trained according to the MISO model as the baseline for experimental comparison. For IRM-MVDR, we use the TCN network to predict the IRM, which is then substituted into the MVDR algorithm for beamforming. For GRNNBF and SARNN, the 4x8 TCN Block is used to predict the CRF mask, which is input to the GRU or self-attention module with 500 hidden units after LayerNorm to output beamforming weights. For all models, we use the joint loss function of SI-SDR and MSE for training, and the weights of the two are equal.

C. Results

Table 1 shows the experimental results of our proposed model and baseline model on the test set. In terms of model parameters, our model has increased compared with IRM-MVDR, which is mainly due to the difference in the prediction mask and the replacement of the MVDR algorithm with a neural beamforming module. Compared with GRNNBF and SARNN, our parameter reduction is more obvious. This is because after adding the cross-attention mechanism based on spatial information, the model does not require a large number of hidden layer units to achieve a satisfactory separation effect.

(a) Noisy, SI-SDR: -3.4dB (b) IRM-MVDR, SI-SDR: 5.4dB

(c) GRNNBF, SI-SDR: 6.91dB (d) SARNN, SI-SDR: 7.81dB

(e) Proposed, SI-SDR: 9.97dB (f) Target

Fig. 6. Spectrum of a piece of data in the test set after model processing. SIR=-2.2dB, SNR=-4.8dB. The angle between the speaker is 9°.

Therefore, the experimental results show that our proposed model can significantly improve the separation performance of the target speech compared with the baseline while reducing the number of parameters.

In Table 2, we present the results of our ablation experiments on the proposed model. The experimental results show that for the pre-separation module, the pre-separation effect obtained by first encoding the input features through the Unet structure and then inputting them to the TCN block to output the mask is better than directly inputting the input features to the TCN through Conv1D. For the neural beamformer, the UNet-TCN structure makes the model more fully utilize the input feature information, reduces the information loss in the dimension reduction process, and makes the estimation of the covariance matrix more accurate. In terms of mask prediction, whether it is TCN or UNet-TCN structure, the effect of network prediction cRM on recovering speech signals is slightly better than that of IRM, but the gap is not large. This is because for frequency-domain speech separation, when the frame length is 32ms, the effect of phase estimation on the separation effect is limited

[21].

For the neural beamforming module, we take multi-head self-attention(MHSA) module with 128 and 256 hidden layer units as an example. It is evident that incorporating the embedding modeled by the covariance matrix and spatial information into the multi-head cross-attention(MHCA) module leads to better speech separation performance than the MHSA module with an equivalent number of hidden layers. Experimental results demonstrate the effectiveness of introducing spatial information into the beamforming module via the cross-attention mechanism.

D. Spectrogram analysis

We analyze and compare the spectrograms of the target speech generated using different separation methods, and discuss the results further. In order to verify the robustness of the algorithm, we selected a piece of data with a low SNR and a small angle between the target speaker and the interference speaker from the test set for visualization, as shown in Fig. 6. Due to numerical instability in the training process and the influence of the MVDR algorithm itself, the IRM-MVDR model has a poor suppression effect on interference noise, and the separated spectrum is severely damaged by noise. In GRNNBF and SARNN using neural beamers, the separation performance of the system has been improved to a certain extent, and both have a good suppression effect on background noise, but there may still be some residual interference noise present in the separated signal. After the proposed model uses the UNet-TCN structure to improve the pre-separation network and adds spatial information to the beamforming module, the background and interference noise are further suppressed, and the degree of spectral distortion is lower than that of the baseline model, achieved better experimental results.

E. Beam pattern

To further analyze the spatial filtering performance of the model, Fig. 7 visualizes the beam patterns of different neural beamformers, including GRNNBF, SARNN and our proposed model. The speech is divided into four segments, segment (a) has only background noise, segment (b) has two speakers speaking at the same time, segment (c) has only the interfering speaker active, segment (d) has only the target speaker active. All beam patterns are averaged over the frequency dimension.

All three models have a strong suppression near 90° when there is no sound source activity, which is a little strange, we don't know if this is due to the influence of background noise. When two sound sources speak at the same time, all three models produce a strong suppression effect on the interference direction. Our proposed model suppresses the disturber to a greater extent when only the disturber is active. When only the target sound source is active, the directivity of our proposed model is better than that of GRNNBF and SARNN, which reduces the degree of distortion of the model-predicted spectrum.

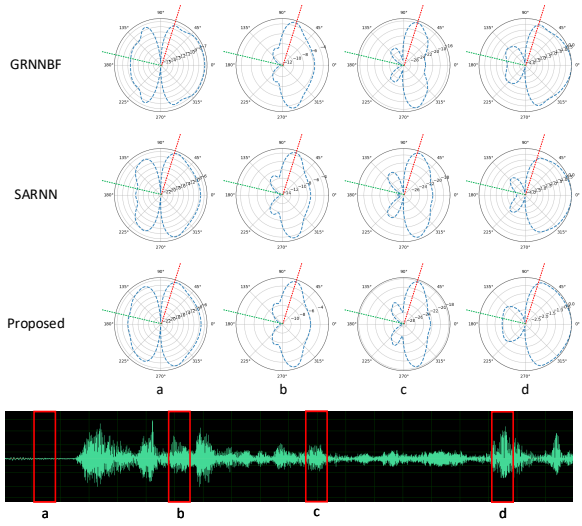


Fig. 7. An example of beam patterns derived by GRNNBF, SARNN and our proposed module. The DOA of the target speaker and the interference speaker are 79 and 164, and marked with red and green respectively.(a) is a silent segment, (b) is two speakers are active at the same time, (c) is only the interference speaker, (d) is only the target speaker.

V. Conclusion

In this study, we propose a novel UNet-TCN structure to model input features, resulting in improved estimation accuracy of the covariance matrix. Furthermore, we introduce spatial information through the cross-attention module in the neural beamforming module to enhance beamformer performance, enabling better noise rejection and reduced spectral distortion. Objective analysis and subjective evaluation show significant improvements in separation effect. In the future, we plan to achieve better target speech extraction while reducing model complexity and output spectrum distortion.

***Abstract*—Most multi-channel speaker extraction schemes use the target speaker's location information as a reference, which must be known in advance or derived from visual cues. In addition, memory and computation costs are enormous when the model deals with the fusion input. In this paper, we propose Speaker-extraction-and-filter Network (SeafNet), which is a low-complexity multi-channel speaker extraction network with only speech cues. Specifically, the SeafNet separates the mixture by utilizing the correlation between an estimation of target speaker on reference channel and the mixed input on rest channels. Experimental results show that compared with the baseline, the SeafNet model achieves 6.4% relative SISNRi improvement on the fixed geometry array and 8.9% average relative SISNRi improvement on the ad-hoc array. Meanwhile, the SeafNet achieves 60% relative reduction in the number of parameters and 42% relative reduction in the computational cost.**

I. Introduction

The cocktail party problem [1] shows the fact that the performance of the speech applications, such as speech recognition, is significantly affected by noise and reverberation in the real world. Speech separation is widely used to deal with this problem by improving the noise robustness of the back-end speech systems. Although most methods work well in the single-channel scenario [2]–[5], the performance declines significantly when the separation system faces a reverberation background. The multi-channel speech separation model with a beamformer is designed to address this issue. Conventional beamforming algorithms can be broadly classified as fixed and adaptive. The fixed beamformer [6] first calculates the time difference of arrival (TDOA) between the reference microphone and the remaining microphones to derive a time-shifted signal for each microphone and then sums up the time-shifted signals to obtain the final beamformer output. The adaptive beamforming algorithms determine the optimal weights of the beamformer through different criteria [7]–[9], the main one of which is the minimum variance distortionless response [8]. In recent years, multi-channel speech separation adopting a learning-based beamformer has become dominant. There are two main routes for these multi-channel speech separation schemes. One class [10]–[12] uses deep neural networks (DNNs) to pre-separate the signals of each channel first, and then estimates the beamformer coefficients based on the pre-separated outputs, or filters the pre-separated outputs directly with a conventional beamformer. The other class [13]–[16], which implicitly employs beamforming in DNN, directly models the mapping relationship between multi-channel inputs and target outputs. Among the aforementioned methods, Filter-and-Sum Network with Transform-Average-Concatenate (FaSNet-TAC) [16] belongs to the latter, and achieves good performance. FaSNet-TAC is a microphone permutation and number invariant model due to the use of pair-wise features. Moreover, in order to overcome the shortcomings of using pair-wise features, FaSNet-TAC adopts TAC operation to fully utilizes the information from all microphones. Experimental results in [16] shows that FaSNet-TAC works well in both fixed geometry array and ad-hoc array. However, the unknown number of speakers and the global permutation problem are still the main obstacles for multi-channel blind speech separation algorithms.

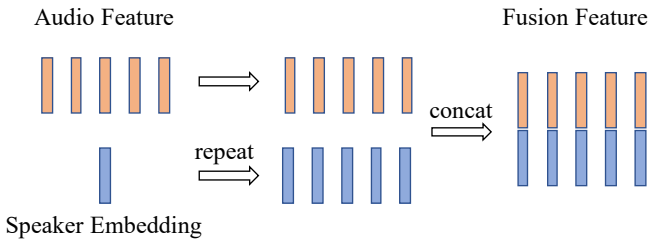

Fig. 1. The tranditional way to use the speaker embedding in target speaker extraction.

Speaker extraction [17], [18], also known as target speech separation, can extract a specific speaker's speech from the mixture with reference information. The speaker's location is commonly used as auxiliary reference information in multi-channel scenarios [19], [20]. However, the speaker's location must be known in advance or extracted from the visual features [21]. Using the speaker embedding from the target speaker's enrollment speech can deal with this issue, yet this will lead to another problem of bigger model size and computational costs due to the relatively high dimensionality of fusion features as shown in Figure 1. This problem is even more serious on multi-channel tasks. In this paper, we extend the FaSNet-TAC [16] model to the multi-channel speaker extraction task. Moreover, to resolve the aforementioned limitations, we propose a relatively low-complexity speaker extraction

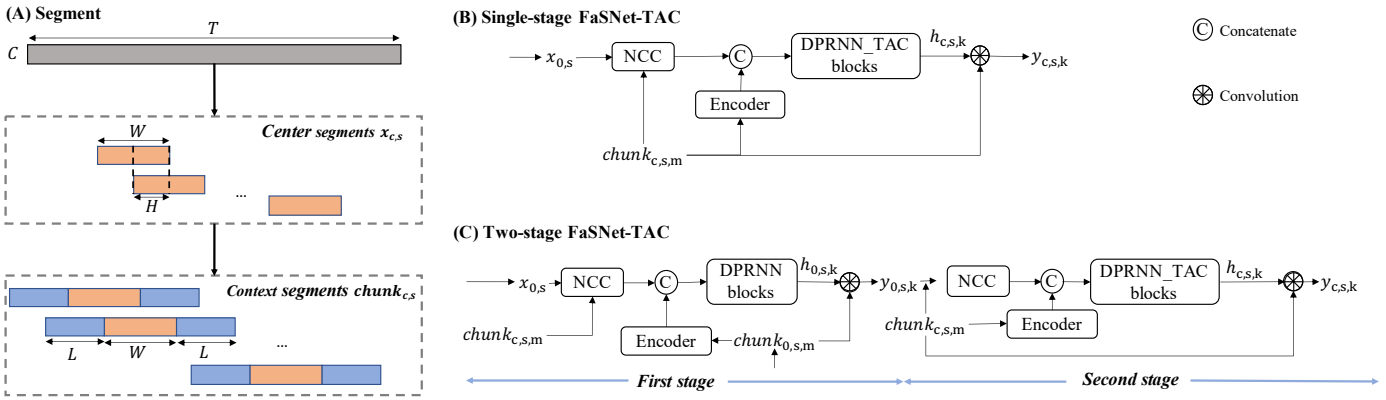

Fig. 2. System flowchart of the origin FaSNet-TAC models. (A) The FaSNet-TAC first splits the input into center segments and context segments. (B) The single-stage FaSNet-TAC model. (C) The two-stage FaSNet-TAC model

network only using speech cues, called Speaker-extraction-and-filter Network (SeafNet). Specifically, the SeafNet first extracts the target speaker's wave of the reference microphone signal by utilizing a reference speech. Then, the SeafNet model computes the Normalized Cross-Correlation (NCC) of this estimation and mixed waveform. The NCC feature contains the content difference between the reference microphone's target speaker estimation and the multi-channel mixed input. Finally, the SeafNet derives the separation result in the same way as the FaSNet-TAC model. In this way, the speaker features only need to be concatenated with the time-domain features of the reference microphone, rather than with the ones of all microphones' signal, significantly reducing the number of parameters and computational costs of the model.

II. Methods

A. Original FaSNet with TAC

FaSNet-TAC is an effective multi-channel blind speech separation solution. Figure 2 (B) and (C) shows the two-stage [15] and single-stage [16] FaSNet-TAC models. As shown in Figure 2 (A), FaSNet-TAC first split the input into center segments with the length of W:

$$\mathbf{x}_{c,s} = \mathbf{x}_c[sH : sH + W - 1] \tag{1}$$

where $\mathbf{x}_{c,s}$ is the center segments, $c \in 0, 1, ..., C-1$ is the c-th microphone of the input, $s \in \mathbf{Z}$ is the index of the segments, and $H \in [0, W-1]$ is the hop size. Then, $\mathbf{x}_{c,s}$ is concatenated with a context window with the length of L on both sides and results $\mathbf{chunk}_{c,s}$:

$$\mathbf{chunk}_{c,s} = \mathbf{x}_c[sH - L : sH + W + L - 1] \tag{2}$$

The two-stage FaSNet-TAC first calculates the Normalized Cross-Correlation (NCC) feature, defined as the cosine similarity between the reference microphone signal and the signal of each remaining microphones. The NCC feature can be formulated as:

$$\begin{cases} \mathbf{chunk}_{c,s,m} = \mathbf{x}_{c,s}[m : m + W - 1] \\ \mathbf{q}_{c,s,m} = \frac{\mathbf{x}_{0,s}(\mathbf{chunk}_{c,s,m})^T}{||\mathbf{x}_{0,s}||_2||\mathbf{chunk}_{c,s,m}||_2} \end{cases}, m = 1, ..., 2L + 1 \tag{3}$$

where $\mathbf{q}_{c,s,m}$ is the NCC feature between $\mathbf{x}_{0,s}$ and $\mathbf{chunk}_{c,s,m}$. $\mathbf{x}_{0,s}$ and $\mathbf{chunk}_{c,s,m}$ is the center segments of the reference microphone and the context segments of the c-th microphone, respectively. The mean of the obtained NCC features $M(\mathbf{q}_{(0,...,C-1),s,m})$ is then concatenated with the context segments' encoding of reference microphone $E(\mathbf{chunk}_{0,s,m})$. Then, the results are fed into N_1 Dual-Path RNN (DPRNN) [5] blocks $\mathscr{F}(*)$ to calculate the beamformer coefficients of the reference microphone $\mathbf{h}_{0,s,k}$ where $k = 0, 1, ..., K-1$. K is the number of the speakers. The estimation of the reference microphone $\mathbf{y}_{0,s,k}$ is then obtained by filtering $\mathbf{chunk}_{0,s,m}$ with the beamformer coefficients $\mathbf{h}_{0,s,k}$:

$$\mathbf{h}_{c,s,k} = \mathscr{F}_{TAC}([E(\mathbf{chunk}_{c,s,m}), \mathbf{g}_{c,s,m}]) \tag{4}$$

$$\mathbf{y}_{s,k} = \mathbf{y}_{0,s,k} + \sum_{c=1}^{C-1} \mathbf{chunk}_{c,s,m} \circledast \mathbf{h}_{c,s,k} \tag{5}$$

Unlike the above two-stage architecture, the single-stage FaSNet-TAC model jointly estimates the beamformer coefficients for all input channels and applies the TAC module between all DPRNN blocks.

B. FaSNet-TAC for Speaker Extraction

We propose two main options for using the FaSNet-TAC to extract the target source. The first solution, called FaSNet-TAC+Sim, is to use the original FaSNet-TAC to obtain the separation results of multiple speakers and then filter the target source through the cosine similarity in the inference stage. The second solution, called Tar-FaSNet-TAC, is to utilize the target speaker embedding during the training stage to obtain a speaker extraction model based on FaSNet-TAC, which can directly extract the target source.

Figure 3 (A) shows the structure schematic Tar-FaSNet-TAC model, which consists of a speaker embedding extraction module and a speaker extraction module. The ResNet34 used as the speaker embedding extraction module in this work is based on [22]. The speaker extraction model consists of N DPRNN blocks with TAC. The speaker embedding extraction module first extract the target speaker embedding $\mathbf{e} \in \mathbb{R}^{1 \times D}$, where D is the dimension of the frequency bins. Then the

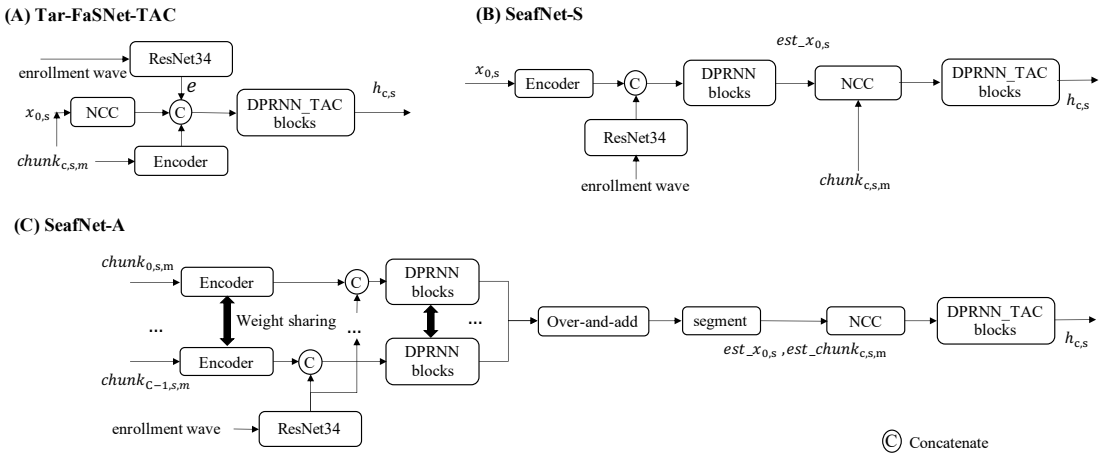

Fig. 3. System flowchart of the SeafNet models. (A) Multi-channel speaker extraction model based on FaSNet-TAC. (B) The SeafNet-S model applies speaker extraction on each microphone. (C) The SeafNet-A model only applies speaker extraction on reference microphone.

speaker extraction module calculates the NCC feature $\mathbf{g}_{c,s,m}$ between the reference signal and multi-channel inputs. The obtained $\mathbf{e}$ and $\mathbf{g}_{c,s,m}$ are then concatenated with the encoder of the context segments $\mathbf{chunk}_{c,s,m}$ to derive the target speaker's filter coefficients $\mathbf{h}_{c,s}$, where $c \in 0, ..., C-1$:

$$\mathbf{h}_{c,s} = \mathscr{F}_{TAC}([E(\mathbf{chunk}_{c,s,m}), \mathbf{g}_{c,s,m}, \mathbf{e}]) \tag{6}$$

Finally, the model generate the estimated target source by filtering multi-channel inputs with $\mathbf{h}_{c,s}$.

C. SeafNet

Although the solutions in Section II-B work well, the model's size and computation costs are significantly increased when processing fusion features. In order to address this problem, we further propose the SeafNet framework. Figure 3 shows the two different structures of SeafNet, named SeafNet-A and SeafNet-S, respectively.

1) SeafNet-A: SeafNet-A in Figure 3 (C) first applies single-channel speaker extraction on the context segments of all input microphones:

$$\mathbf{est}_{c,s,m} = \mathscr{F}([E(\mathbf{chunk}_{c,s,m}), \mathbf{e}]), \quad c = 0, ..., C-1 \tag{7}$$

where $\mathscr{F}(*)$ indicates the DPRNN blocks, C indicates the number of microphones, and $\mathbf{e}$ is the target speaker embedding. Next, we obtain the center segments $\mathbf{est_x}_{c,s}$ and context segments $\mathbf{est_chunk}_{c,s,m}$ of the pre-separated output through overlap-and-add and split operation. Then SeafNet-A calculates the NCC feature between $\mathbf{est_x}_{0,s}$ and $\mathbf{est_chunk}_{c,s,m}$ and estimates the target speaker's filter coefficients:

$$\mathbf{g}_{c,s,m} = \frac{\mathbf{est_x}_{0,s}(\mathbf{est_chunk}_{c,s,m})^T}{||\mathbf{est_x}_{0,s}||_2||\mathbf{est_chunk}_{c,s,m}||_2} \tag{8}$$

$$\mathbf{h}_{c,s} = \mathscr{F}_{TAC}([E(\mathbf{est_chunk}_{c,s,m}), \mathbf{g}_{c,s,m}]) \tag{9}$$

where $\mathscr{F}_{TAC}(*)$ indicates the DPRNN with TAC blocks. Finally, $\mathbf{h}_{c,s}$ are convolved with $\mathbf{est_chunk}_{c,s,m}$ and generate the separation results like the original FaSNet-TAC.

2) SeafNet-S: SeafNet-S in Figure 3 (B) first applies single-channel speaker extraction only on the reference microphone's center segments, not on the context segments of all microphones as in the SeafNet-A model:

$$\mathbf{est}_{0,s} = \mathscr{F}([E(\mathbf{x}_{0,s}), \mathbf{e}]) \tag{10}$$

where $E(\mathbf{x}_{0,s})$ indicates the encoder of the reference microphone's center segments. $\mathbf{e}$ is the target speaker embedding. Then SeafNet-S calculates the NCC feature $\mathbf{g}_{c,s,m}$ between $\mathbf{est}_{0,s}$ and all microphones' context segments $\mathbf{chunk}_{c,s,m}$. The target speaker's filter coefficients can be calculated as:

$$\mathbf{g}_{c,s,m} = \frac{\mathbf{est}_{0,s}(\mathbf{chunk}_{c,s,m})^T}{||\mathbf{est}_{0,s}||_2||\mathbf{chunk}_{c,s,m}||_2} \tag{11}$$

$$\mathbf{h}_{c,s} = \mathscr{F}_{TAC}([E(\mathbf{chunk}_{c,s,m}), \mathbf{g}_{c,s,m}]) \tag{12}$$

At last, $\mathbf{h}_{c,s}$ are convolved with $\mathbf{chunk}_{c,s,m}$ and generate the final estimation.

III. Experiment Setup

A. Dataset

Datasets for speaker embedding extraction module: We use the development set of the VoxCeleb2 [23], which contains over 1 million utterances from 5991 speakers, to train a ResNet34-based speaker verification model. We use the test set of the VoxCeleb1 [23] for testing. The test set contains 4715 utterances from 40 celebrities and has no overlap with the identities in the VoxCeleb2.

Datasets for speaker extraction module: We use the same dataset in [16], a multi-channel two-speaker noisy reverberant dataset with both ad-hoc and fixed geometry microphone arrays. Each class of microphone array includes 20000, 5000, and 3000 4-second long utterances for training, validation and test, respectively. The source utterances in these multi-channel mixed waveform are selected from the 100-hour Librispeech [24], and we randomly select an additional utterance as the enrollment waveforms for each source.

B. Implementation details

Speaker embedding extraction module: We use the default ResNet34V2[1] to extract a 256-dimensional embedding for the target speaker. Specifically, we use the SAP [25] encoder and the ge2e [26] loss function in our training.

Speaker extraction module: We have compared the performance of four models: 1) FaSNet-TAC[2]+Sim, 2) Tar-FaSNet-TAC, 3) proposed SeafNet-A, and 4) proposed SeafNet-S. The results in 1) are the baseline. We use 4 DPRNN blocks in all models and the hyperparameters are the same as [16]. Specifically, we apply TAC between all the DPRNN blocks in 1) and 2), while in 3) and 4) we use it only in the last two blocks. The length of the center segment W is 4ms and the length of context segment L is 16ms. The scale-invariant SNR (SISNR) [27] is used as the training target. The SISNR improvement (SISNRi) is used as the separation performance metric. In addition, we evaluate the FLOPs and Params information of all models.

IV. RESULTS AND DISCUSSIONS

Table I shows the experimental results on the 6-mic fixed geometry array. Among all schemes, the Tar-FaSNet-TAC model obtained the maximum SI-SNRi improvement, which achieved 1.23 dB SISNRi improvement over the baseline. However, its FLOPs' cost increases significantly because the dimensionality of the fusion features is much larger than the one of the original model inputs. The SeafNet-A further reduces the number of model parameters, but the FLOPs cost is still higher than the baseline due to the iterative pre-separation of each microphone. The SeafNet-S model has a comparable separation performance to the SeafNet-A model, which achieves a 6.4% relative improvement over the FaSNet-TAC+Sim baseline model. It can be noticed that the proposed SeafNet-S method has the lowest model size and computational cost.

Table II shows the results on ad-hoc array and we only report the results on 2, 4, and 6 microphones to compare with [16]. The results in Table II shows similar trends as in Table I. Specifically, the Tar-FaSNet-TAC model achieves the largest SISNR improvement, but accompanied with an increase in FLOPs' costs. The SeafNet-S model achieves 3.5% relative SISNRi improvement, 42% relative FLOPs reduction, and 60% relative Params reduction against the baseline (6-mic), respectively. We note that in the 2-mic scenario, the SeafNet-S still outperforms the baseline, but there is a slight degradation in the performance compared to the SeafNet-A model. It may be because the output of pre-separation account for a notable contribution to the calculation of the NCC features, which could greatly affect the separation performance of the model.

Although the SISNRi performance of our proposed SeafNet-A and SeafNet-S is slightly lower than that of Tar-FaSNet-TAC, the SeafNet model outperforms the Tar-FaSNet-TAC model by a large margin in terms of Params' and FLOPs' cost. In addition, the results in Table I and Table II show that SeafNet-S outperforms the baseline on both fixed geometry array and ad-hoc array with lower Params' and FLOPs' cost. It means that for the speaker extraction task, the improvement brought by our proposed SeafNet models is quite effective.

V. CONCLUSION

In this work, we extend the FaSNet-TAC model to multi-channel target speaker extraction task and propose a Speaker extraction-and-filter Network (SeafNet). SeafNet first extracts the target source from the signal of the reference microphone by utilizing auxiliary speech. Then, SeafNet calculates the NCC feature between the estimated target source and multi-channel input. Finally, SeafNet derives a set of filter coefficients using the fusion feature of the input and NCC feature. The filter result of the input is our final output. Experimental results show that our proposed SeafNet achieves a favorable separation performance improvement while maintaining relatively small model size and low computational costs.

Modeling Suprasegmental Information Using Finite Difference Network for End-to-End Speaker Verification

Jin Li*, Man-Wai Mak*, Nan Yan†, Lan Wang†

***Abstract*—In recent years, using raw waveforms as input to deep networks has been widely explored for speaker verification systems that process speech signals at the segmental level. A critical issue of such an approach is that the front-end network with a small kernel fails to capture the suprasegmental information, such as the intonation patterns and prosody that span longer than one second. This paper proposes a novel framework that can capture the segmental and suprasegmental information after the first convolutional layer. Concretely, suprasegmental information is obtained from the first-order finite difference of two consecutive suprasegmental envelopes estimated by Hilbert transforms. Experimental evaluations on the Voxceleb dataset show that combining segmental and suprasegmental features can reduce the EER of an end-to-end system by 27%. To our best knowledge, this is the first attempt to incorporate suprasegmental information for end-to-end speaker verification.**

I. Introduction

Speaker verification (SV) aims to verify whether the same speaker speaks the enrollment and test utterances. In previous studies of deep speaker embedding, acoustic features – such as filterbanks – were commonly used as the input to deep neural networks (DNNs) [1]. By contrast, many recent studies [2]–[6] explored using raw waveforms as the input and demonstrated satisfactory performance. For example, to extract useful information from waveforms, Ravanelli and Bengio [2] designed filters parametrized by sinc functions for the first layer of an end-to-end (e2e) network. In RawNet [6], convolutional residual blocks are used for frame-level processing, and GRUs are then used for aggregating the frame-level features into an utterance-level embedding. Feature map scaling and shifting have been applied to increase speaker discrimination in RawNet [3]. More recently, Kim *et al.* [5] used the ResNeXt structure to make the front end deeper and wider. Jung *et al.* [7] improved RawNet2 by exploring the combination of Res2Net and multi-layer feature aggregation. Wav2Spk [4] sets the stride and kernel size so that the output corresponds to 30ms and 10ms frameshift, similar to wav2vec [8]. Because these previous studies utilized small convolutional kernels, the resulting networks can only capture speakers' characteristics at the segmental level. This restriction means that depending on the network depth, the time scale of these networks is only one to several phones.

We propose a novel framework to increase the time scale to extract both subsegmental and suprasegmental features (see Figure 1). Like conventional CNN-based speaker embedding networks, segmental information – such as vowels and consonants – can be preserved. Importantly, the framework is also designed to preserve suprasegmental information such as intonation patterns, rhythm, and pitch [9]. Both segmental and suprasegmental features enable humans to distinguish speakers. The former is affected by speakers' physical traits, whereas

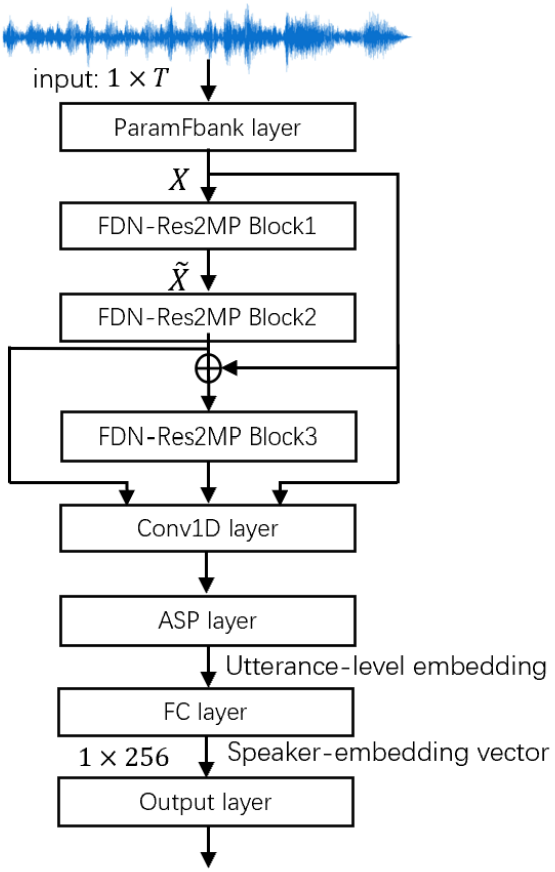

Fig. 1. The architecture of the proposed framework: FDN-Res2MP-Net. It uses pre-emphasized speech waveforms as input and produces speaker posteriors as output.

979-8-3503-0067-3/23/$31.00 ©2023 IEEE

the latter is determined by how speakers use spoken languages to convey the messages [10]. Suprasegmental features have been used for speaker recognition [11], [12]. However, they have not been explored in an e2e manner with raw waveforms as input.

We extract suprasegmental information after the first convolutional layer because the first convolutional layer with small kernels emphasizes speaker information at low frequencies (below 1000 Hz) and models the fundamental frequency of speech signals [13]. The suprasegmental features are obtained by computing the first-order finite difference between two adjacent suprasegmental envelopes, each with around 3 seconds. The suprasegmental features are combined with segmental features at the output of each FDN-Res2MP block in Figure 1. Because the envelopes change slowly and have duration covering words, they contain suprasegmental information across phones, syllables, and phrases [14], [15]. As a result, it is possible to extract speaker-discriminative prosody information from the first-order finite difference between two adjacent envelopes. In addition to using envelopes, we have also attempted to capture the prosody from the temporal feature maps at the output of the first convolutional layer, as shown in Figure 2(b). Our experimental results show that the suprasegmental features extracted by this approach benefit speaker verification.

Our main contributions are as follows:

1) A novel plug-and-play module with first-order Finite Difference Networks (FDN) is proposed to capture suprasegmental features that preserve prosody information.
2) We demonstrate that useful suprasegmental features can be extracted from raw temporal feature maps without computing the feature maps' envelopes.
3) We demonstrate that combining segmental and suprasegmental features enables e2e SV systems to achieve very competitive performance.

II. Methodology

A. System Architecture

Figure 1 shows the structure of the proposed speaker embedding networks. The building blocks are similar to that of RawNet3 [7]. It comprises a parametrized complex-valued analytic filterbanks (ParamFbank) layer [16], residual blocks, an attentive statistics pooling (ASP) layer, a 1D convolution layer, a fully-connected (FC) layer, and an output layer. The ParamFbank is an extension of the SincNet filter that captures speakers' pitch and formants. The motivation for using complex-valued representations is that they allow perfect synthesis via the overlap-and-add method. The output of the first layer is input to three consecutive residual blocks, named FDN-Res2MP in Figure 1.* The three consecutive blocks capture information at different temporal scales. Unlike RawNet3, α-feature map scaling (AFMS) is not applied. Instead, an FDN is added to the front of each residual block to extract suprasegmental information. Next, an attentive statistics pooling layer aggregates the frame-level features to an utterance-level embedding, which is then fed into a fully-connected layer. The speaker embedding is extracted from the output of the fully-connected layer. The number of nodes in the output layer is the same as the number of training speakers.

During training, AAM-softmax loss [17] was employed to compute the error between the speaker labels and speaker posteriors.

B. Operations of FDN-Res2MP Blocks

In one mode of operation of the FDN-Res2MP Blocks in Figure 1, the FDN extracts suprasegmental information from the envelopes of the feature maps ($[x_1, \ldots, x_{C/\alpha}]$ in Figure 2(a)). We used Hilbert transforms [26] to compute the envelopes. We denote the FDN as "FDN-E" when the FDN-Res2M Blocks are operated in this mode. In another mode of operation, the FDN is directly operated on the raw feature maps without computing the envelopes, as shown in Figure 2(b). We denote the FDN as "FDN-W" when the FDN-Res2M Blocks are operated in this mode.

Let $X = \{x_i\}_{i=1}^{C} \in \mathbb{R}^{C \times T}$ be the feature maps of a frame-level representation after the first ParamFbank layer, where C is the number of channels and T is the sequence duration. The number of channels in X is first squeezed from C to $\frac{C}{\alpha}$ by 1D convolution with kernel size of 1. This squeezing operation is to reduce computation. Then, the 1D-convolutional filters' outputs are partitioned into overlapping suprasegments by a large sliding window along the time axis for each channel. Figure 2(a) shows an example of two suprasegments with length T'. Note that the number of suprasegments depends on the signal duration (T) and the window overlapping. For clarity, Figure 2(a) illustrates two suprasegments and indicates them by the segment labels a and b, respectively.† The envelopes of two segments $e_{\cdot,a}$ and $e_{\cdot,b}$ are obtained by Hilbert transforms [26]. The prosody is then calculated by computing the first-order finite difference between the two suprasegments for each channel:

$$\hat{e}_i = \mathsf{ReLU}(\mathsf{Conv}(e_{i,b}, W_2)) - \mathsf{ReLU}(\mathsf{Conv}(e_{i,a}, W_1)), \quad (1)$$

where W_1 and W_2 are learnable parameters for 1D convolution and i represents the i^{th} channel. The prosody across different channels is summarized by global average pooling along the time axis:

$$\bar{e}_i = \frac{1}{T'} \sum_{t=1}^{T'} \hat{e}_{i,t} \qquad i = 1, \ldots, \frac{C}{\alpha}. \quad (2)$$

The pooled vector $\bar{e}$, which contains the global prosody information, is projected to a C-dimensional space through a fully connected (FC) layer. A sigmoid function is then applied independently to individual dimensions to scale the values to a range compatible with the ParamFbank's output, i.e.,

*The name Res2MP is adopted from [7].

†The concept can be generalized to multiple suprasegments. In such a case, the finite difference is applied to adjacent suprasegments, followed by averaging their differences.

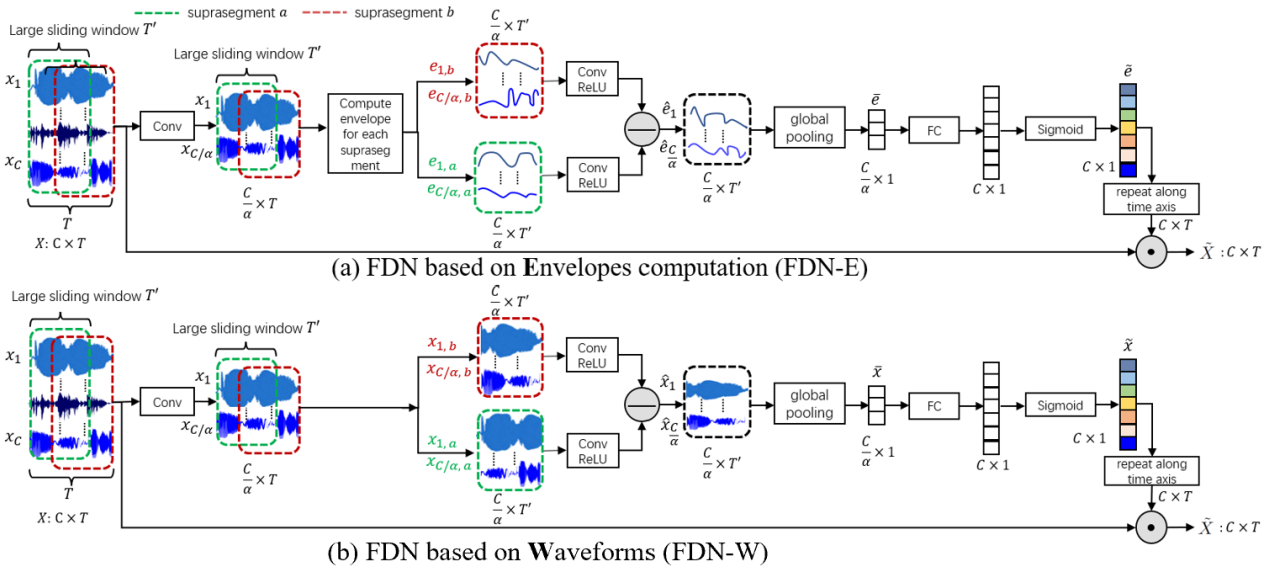

Fig. 2. Signal flow diagrams showing the operation of the FDN module in Figure 1. The module can be inserted into the front of each residual block in Figure 1. In (a), Conv represents 1D convolution aiming to reduce computation. It squeezes the number of channels from C to C/α. Then, the suprasegments are produced using a large sliding window with 3.07s and a frameshift of 0.47s. The prosody is computed by the first-order difference between the two envelopes obtained from the Hilbert transform. Global pooling is used to summarize the prosody corresponding to each channel. Then, the number of channels is recovered to the same as that of the input using a fully connected (FC) layer. The sigmoid activation function is then applied to the channels independently. Finally, the prosody is fused with the input waveforms X along each channel using a channel-wise dot product. In (b), the suprasegmental information is extracted directly from the feature maps.

$\tilde{e} = \sigma(f(\bar{e}, W_3))$, where $f()$ is the FC layers' operation and W_3 denotes its learnable weights. $\tilde{e}$ is repeated T times along the time axis before performing elementwise multiplication (Hadamard product) with the input feature map as shown in Figure 2(a).

The FDN-W in Figure 2(b) is similar to FDN-E, except that the finite differences are based on the feature maps instead of the envelopes.

III. Experiments

A. Datasets

We used the VoxCeleb2 development set [18] for training and the VoxCeleb1 test set [27] to evaluate the model performance. VoxCeleb2 consists of more than one million utterances from 6112 speakers, and VoxCeleb1 contains approximately 330 hours of recordings from 1251 speakers for text-independent tasks.

B. Experimental Configurations

1) Backbones: Two types of neural networks were used as the backbone networks: RawNet and Res2MP-Net.

RawNet. It is the backbone network for the first baseline system. This backbone is similar to the architecture in [6], but the speaker embedding dimension is 1024. A GRU layer with 1024 nodes aggregates frame-level features into an utterance-level embedding. Following [6], utterances were either cropped or duplicated (concatenated until the desired length has been reached) to 3.59s in the training phase. Softmax loss was used during training. There was no data augmentation during the training phase.

FDN-W-RawNet. It is a RawNet with FDNs, where an FDN was inserted in the front of the "Res block" in Table 1 of [6]. In the FDN, the sliding window size (T' in Figure 2) and shift are 3.2s and 0.5s, respectively. The channel reduction ratio α was set to 8. Other settings are the same as RawNet.

Res2MP-Net. It is the backbone network for the second baseline system. The network does not have any FDN module. It was trained using randomly cropped 4-second utterances. AAM-softmax loss [17] was applied with a margin of 0.1 and a scale of 30. We added MUSAN noise [28] and applied room impulse response (RIR) simulations [29] as data augmentation.

FDN-Res2MP-Net. It is an Res2MP-Net with an FDN for each Res2MP block in Figure 1. For the FDNs, the channel reduction ratio α was set to 4. The sliding window size and shift were set to 3.07s and 0.47s, respectively. Other settings are the same as Res2MP-Net.

For all networks, an Adam optimizer [30] with a learning rate of 0.001 was used, and weight decay of $5e^{-5}$ was set.

C. Results Analysis

Performance is reported in terms of Equal Error Rate (EER), where the false accept rate and false reject rate are equal, as well as the minimum Detection Cost Function (minDCF).

As shown in Table I, the system with FDN-W outperforms the baseline system (Res2MP-Net), which does not contain any FDN. This result demonstrates that suprasegmental information improves the system's accuracy and helps improve speaker

discrimination. Results also suggest that it is possible to train convolutional filters to capture prosody information from raw speech in a data-driven way. However, the performance does not improve when the network complexity increases. To balance the performance and the computation complexity, we found that $\alpha = 4$ is appropriate for the FDN-Res2MP-Net. Table I also compares the performance of FDN-based systems with other SV systems based on raw waveforms and hand-craft features. The results show that FDN-E improves performance on the VoxCeleb1 test set. However, the performance of FDN-E is poorer than FDN-W. The inferior performance of FDN-E is caused by the strong assumption that speech is a modulated signal.

Table II shows the ablation study that explores the positions

TABLE IV
PERFORMANCE OF DIFFERENT SEGMENT DURATIONS IN EACH FDN-W IN THE FDN-W-RAWNET ON THE VOXCELEB1 TEST SET.

Segment Duration	Number of Segments	EER (%)

1.9	3	2.48
0.5	4	2.49

and the number of FDN-W modules inserted into the network. The results show that FDN-W performs better when it is added to the deeper Res2MP block. In addition, inserting the FDN-W into all blocks achieves the best performance because more suprasegmental information can be obtained.

(a) 2 suprasegments with 3.2s and 0.5s shift (b) 3 suprasegments with 1.9s and 0.9s shift

(c) 4 suprasegments with 0.5s and 0.3s shift

Fig. 3. Different numbers of suprasegments and different durations for the FDN-W-RawNet.

To verify the effectiveness of the squeezing operation in FDNs, we varied the reduction ratio α in the FDN-Res2MP-Net. Table III shows the performance and the number of parameters when α increases. The results show that setting α to 4 achieves a good balance between network size and performance. This setting also makes the FDN-Res2MP-Net outperforms the baseline Res2MP-Net.

To investigate the importance of suprasegment duration, we varied the window size and window shift shown in Figure 3, where each suprasegment is denoted by $\hat{x}$ in Figure 2(b). We applied the windowed suprasegments in Figure 3 to FDN-W-

RawNet. When the number of suprasegments is larger than two, the differences between adjacent suprasegments were linearly combined by trainable attention weights. The results are shown in Table IV, which show that when the suprasegment duration decreases, the EER increases, suggesting that long suprasegments contain more prosody information.

IV. Discussion

Stadelmann and Freisleben [31] suggested that incorporating suprasegmental information is likely to enhance speaker clustering performance. In their experiments, they used a suprasegment length of up to 496 ms to capture speaker-specific sounds. Stadelmann *et al.* [32] further showed that increasing the suprasegment length from 400 ms to 1000 ms can provide useful prosodic information to reduce the misclassification rate of a speaker clustering task.

Our framework uses a finite difference network spanning across words to capture suprasegmental information. The difference between two overlapping suprasegmentals further emphasizes the suprasegmental information. The inclusion of suprasegmental information offers two advantages. Firstly, it enables the front-end network to focus on the pitch and F1 profiles, which cannot be extracted without the FDN in the front end. Secondly, the suprasegmental features compensate for the limitation of small convolutional kernels in end-to-end systems where raw waveforms are used as input.

V. Conclusions and Future Work

This paper proposes a novel framework that uses segmental and suprasegmental information for end-to-end speaker verification. The segmental features convey speaker information at the scale of phones, whereas suprasegmental features characterize the prosody of speakers. We achieve this goal through a finite difference network. Experimental results show that combining phone- and prosody-level features can improve the performance of the VoxCeleb1 test set. However, the average utterance duration of VoxCeleb is around 4 seconds, which limits the number of suprasegments within an utterance. In the future, we will explore other corpora that have longer utterances. In addition, we will visualize and analyze the influence of FDNs through the time-frequence response.

Relevance of Quadrature Phase For Replay Detection in Voice Assistants (VAs)

Priyanka Gupta, Piyushkumar K. Chodingala, and Hemant A. Patil
DA-IICT, Gandhinagar, India.
E-mail: {priyanka_gupta, piyush_chodingala, hemant_patil}@daiict.ac.in

***Abstract*—There have been various studies involving Instantaneous Frequency (IF) estimation for Spoofed Speech Detection (SSD) task, such as the derivative of the phase obtained by Hilbert Transform (HT) approach and Energy Separation-based method. However, IF estimation by HT leads to lack of good temporal resolution. On the other hand, ESA-based method leads to excellent time resolution, however, lacks the relative phase information. Therefore, in this paper, we have proposed Cochlear Filter Cepstral Coefficients-based Instantaneous Frequency using Quadrature Energy Separation Algorithm (CFCCIF-QESA) feature set, which merits of having an excellent time resolution as well as inclusion of the relative phase information. Hence, we illustrate the significance of incorporating the quadrature-phase component along with the in-phase component for SSD of replay detection in VAs. To that effect, we perform experiments on the Realistic Replay AttackF Microphone-Array Speech Corpus (ReMASC) dataset. Furthermore, the proposed CFCCIF-QESA feature set gives 28.71 and 29.89 %EER using GMM and CNN respectively, on Eval set. The proposed feature set is evaluated using various performance metrics, including EER and other confusion matrix-based metrics. Finally, the latency for CFCCIF-QESA and CFCCIF-ESA is presented, showing the better suitability of the proposed CFCCIF-QESA feature set w.r.t. practical deployment.**

Index Terms: Spoofed Speech Detection, Mutual Information, Quadrature Phase, Energy Separation Algorithm

I. Introduction

Voice enabled systems, such as Automatic Speaker Verification (ASV) systems and Voice Assistants (VAs) are widely used. However, these systems also undergo various security concerns, such as spoofing by mimicry, Voice Conversion (VC), Speech Synthesis (SS), and replay. Amongst these, replay attack is the easiest to mount but hard to detect, since it requires only simple recording and playback devices. In particular, an attacker without any technical expertise, can gain illegal access by mounting a replay attack. VAs, such as Google Home, Alexa, Siri are very commonly used these days in households. These voice-driven interfaces provide hands-free operation, where users can focus their attention to some other task, while giving voice commands to a VA. These systems have enhanced the ease of managing multiple tasks at a time, using voice commands, however, at the same time, they also need to have robust security [1]. Some of the attacks pertaining to VAs are hidden voice commands [2], adversarial attacks [3], and self-triggered attacks [4]. To that effect, countermeasures have been proposed in the literature to defend against these attacks [4], [5].

However, for the detection of spoofing attacks, particularly replay attacks, most of the countermeasures or Spoofed Speech Detection (SSD) systems have been designed in the context of ASV systems, leveraged by bi-annual organization of ASVSpoof challenges during INTERSPEEECH in 2015, 2017, 2019, and 2021. Notably, the countermeasures designed for ASV systems might not work as efficiently for VAs as well. This is due to substantial differences between an ASV system and a VA. In particular, an ASV system usually comprises a single microphone (i.e., one channel), and the user is in a controlled environment. However, this is not the case for VAs, which are designed with microphone array (i.e., multi-channel) to capture speech from various directions and varying distances. Given the usage scenarios of VAs, the user is not in a controlled environment and can have different acoustic environments.

To that effect, in order to detect replay attacks on VAs, Energy Separation Algorithm (ESA)-based Instantaneous Frequency (IF) has been proposed in the past in the context of ASV systems [6]. Another technique to estimate IF is by differentiating the phase of the analytic signal obtained using the Hilbert transform. However, this technique has a poor resolution in the time domain (as it requires a block (or frame) of speech data) [7]. To get a better time resolution, recently, an extension of Cochlear Filter Cepstral Coefficients-based Instantaneous Frequency (CFCCIF) was proposed as CFCCIF-ESA in [6]. The CFCCIF-ESA is based on cochlear filtering followed by estimation of IF using the conventional Teager Energy Operator (TEO)-based ESA [8], [7], [9]. TEO is known to estimate energy using only the *amplitude of real signals.* Consequently, in [6] the information pertaining to only the amplitude of the signal is used for the synthetic SSD task. Even though this approach is known to have better time resolution, it falls short of the contribution made by the quadrature-phase component, which is derived from HT. Therefore, in order to have both merits, we use the *extended-definition of TEO*, which leads to our proposition of CFCCIF-QESA (Quadrature-based ESA) feature set for replay detection in VAs.

Apart from this, the rationale behind choosing the quadrature-phase (90°) component along with the in-phase component is shown by a Mutual Information (MI)-based analysis, described in further detail in Section II. As a result, CFCCIF-QESA feature set is proposed in this work, and evaluated its performance on the Realistic Replay Attack Microphone-Array Speech Corpus (ReMASC) dataset. To fur-

979-8-3503-0067-3/23/$31.00 ©2023 IEEE

ther examine the efficiency of our proposed feature set, model-level comparison is performed on the Gaussian mixtures of the genuine *vs.* spoof class for the CFCCIF-ESA and CFCCIF-QESA feature sets. In this regard, the Kullback–Leibler (KL) divergence is estimated for both features. Lastly, we have estimated the latency period of the proposed feature set to investigate its capacity for practical SSD system deployment.

II. Proposed Work

This work proposes the incorporation of a quadrature phase in the existing CFCCIF-ESA feature set. This is done by using the extended definition of TEO.

A. Motivation for quadrature phase

So far, commonly used features have been based on the magnitude spectrum of the speech signal, however, phase information is also shown to be important for many speech applications [10], [11]. Here, we have first shown the significance of a quadrature phase ($90°$) over the other phase angles using MI-based analysis. Mathematically, using the joint and marginal probability density functions (*pdfs*) of S1 and S2, the MI is [12]:

$$I(S1;S2) = \int_{s1}\int_{s2} f_{S1S2}(s1,s2)\log_2\left(\frac{f_{S1S2}(s1,s2)}{f_{S1}(s1)f_{S2}(s2)}\right)ds1ds2. \tag{1}$$

Here, amount of information between a signal (as shown in eq. (2)) and its corresponding phase-shifted versions is measured by MI [12]. The signal in eq. (2) is an AM-FM signal (shown in Fig. 1 (a)), which is used to model speech signals [8], [14]. The MI obtained corresponding to varying relative phase of this signal is shown in Fig. 1 (b).

$$\begin{aligned} a(t) &= \left(1 + 0.7cos\left(\frac{\pi}{40}t\right)\right), \\ x(t) &= a(t)\cos\left(\frac{\pi}{3}t + 5sin\left(\frac{\pi}{30}t + \left(\frac{\pi}{4}\right)\right)\right). \end{aligned} \tag{2}$$

The *optimal* phase is the angle at which MI is observed to be the minimum. From Fig. 1 (b), it can be seen that the minimum MI obtained is achieved at 90 degrees, (i.e., quadrature).

Algorithm 1: Estimation of Mutual Information (MI)

Input: Input: Signals S1 and S2 having equal lengths n
Output: Output: MI
/* According to Freedman-Diaconis Rule [13] */
1 $width1_bin = 2\frac{IQR(u)}{\sqrt[3]{n}}$, where IQR is Inter-Quartile Range
2 $width2_bin = 2\frac{IQR(v)}{\sqrt[3]{n}}$
3 $avg_bins = avg(width1_bin, width2_bin)$
4 Generate histograms of S1 and S2 using avg_bins
5 Get H(U) and H(V) from the probability values computed from the histograms
6 Using the probability values, compute the joint probability
7 Estimate the MI

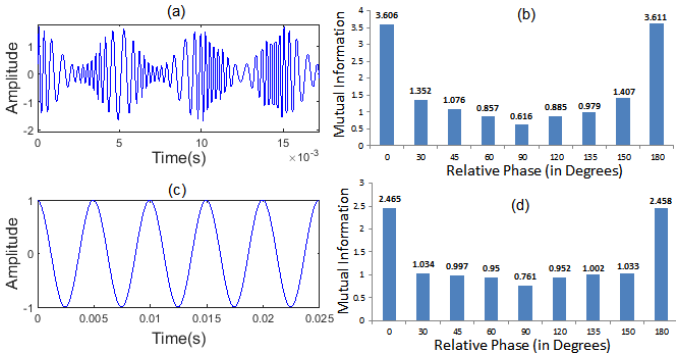

Fig. 1. The effect of varying the relative phase of (a) AM-FM signal, (b) its corresponding MI, (c) cosine signal, and (d) its corresponding MI.

Furthermore, a similar analysis by considering a cosine signal is also shown in Fig. 1 (c). The motivation for this is the significance of the quadrature phase even in the definition of Fourier transform. In particular, the Fourier transform of the signal $x(t)$ is given by [15]:

$$\begin{aligned} \mathcal{F}\{x(t)\} = X(\omega) &= \int_{-\infty}^{\infty} x(t)e^{-j\omega t}dt, \\ \therefore X(\omega) &= \int_{-\infty}^{\infty} x(t)\cos(\omega t)dt - j\int_{-\infty}^{\infty} x(t)\sin(\omega t)dt, \\ \therefore X(\omega) &= X_R(\omega) + jX_I(\omega) = |X(\omega)|e^{j\measuredangle X(\omega)}, \\ \therefore \measuredangle X(\omega) &= tan^{-1}\left(\frac{X_I(\omega)}{X_R(\omega)}\right). \end{aligned} \tag{3}$$

$$x(t) = \frac{1}{2\pi}\int_{-\infty}^{+\infty} X(\omega)e^{j\omega t}d\omega. \tag{4}$$

Using the fundamental theorem of integral calculus,

$$\begin{aligned} \therefore x(t) &= \frac{1}{2\pi}\lim_{\omega_0\to 0}\sum_{n=-\infty}^{+\infty}\left[X(\omega_n)\omega_0\right]e^{j\omega_n t} \\ x(t) &= \frac{1}{2\pi}\lim_{\omega_0\to 0}\sum_{n=-\infty}^{+\infty}\left(|X(\omega_n)|\omega_0\right)e^{j(\measuredangle(X\omega_n)+\omega_n t)}, \end{aligned} \tag{5}$$

where ω_0 is the step size (width), and $\omega_n = n.\omega_0, n \in Z$. Eq. (3) shows that $\measuredangle X(\omega) = 0$ for $X_I(\omega) = 0$. Furthermore, from eq. (5), it can be concluded that $\measuredangle X(\omega)$ provides the relative phases of the complex exponentials that *make up* the signal $x(t)$ [15]. As observed from Fig. 1 (c) and Fig. 1 (d)), we obtain a minimum MI at $\pi/2$ (i.e., $cos(\omega t)$ and $sin(\omega t)$. Given this MI-based analysis, we have proposed the inclusion of the quadrature-phase component of the detection of spoofed speech, and hence the *Quadrature*-based ESA (i.e., QESA). The proposed QESA uses the *extended* definition of the TEO in order to include the quadrature phase in the signal.

B. Using Extended Definition of TEO

The quadrature phase-shift is incorporated by estimating the analytic signal by computing HT. Given the analytic signal is complex-valued, it shows *causal* behavior in the frequency

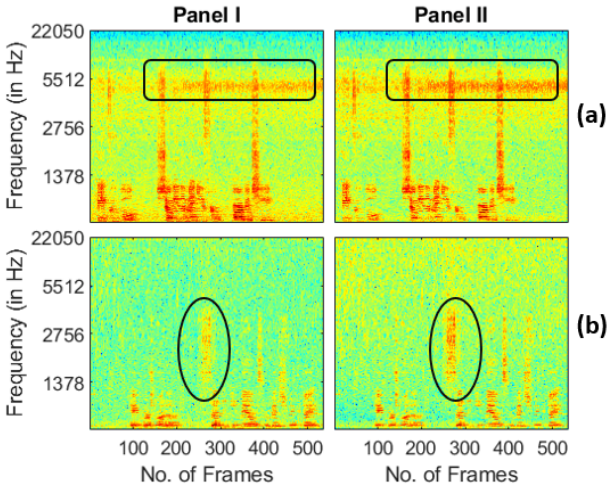

Fig. 2. Panel I and Panel II correspond to the spectrograms of CFCCIF-ESA and CFCCIF-QESA feature sets, respectively, where (a) is the genuine speech signal, and (b) is the spoofed (replay) speech signal.

domain. Further, to estimate the energy of this complex-valued signal, we exploit the extended definition of the TEO on a complex-valued signal $x_z(t)$, i.e., $\psi_c[x_z(t)]$ is given by [16]:

$$\psi_c[x_z(t)] = x_z(t)\dot{x_z}^*(t) - \frac{1}{2}[\ddot{x_z}(t)x_z^*(t) + x_z(t)\ddot{x_z}^*(t)], \quad (6)$$

where $\dot{}$ and $\ddot{}$ denote the differentiation and double differentiation operators, respectively. Given that $x_z(t)$ is complex, the TEO defined in eq. (6) is applied on real and imaginary parts of $x_z(t)$. In particular,

$$\psi_c[x_z(t)] = \dot{x_{z_R}}^2(t) + \dot{x_{z_I}}^2(t) - x_{z_R}(t)\ddot{x}_{z_R}(t) - x_{z_I}(t)\ddot{x}_{z_I}(t). \quad (7)$$

When $x_z(t)$ is complex, eq. (7) can be re-written as [17]:

$$\psi_c[x_z(t)] = \psi[x_{z_R}(t)] + \psi[x_{z_I}(t)]. \quad (8)$$

In this work, using eq. (8), we have extracted TEO-based energy of the analytic signal for improved estimation of energy as a part of ESA, which is discussed in detail in the next sub-Section.

C. CFCCIF-QESA Feature Extraction Procedure

The feature extraction procedure of the proposed CFCCIF-QESA feature set is illustrated in Fig. 3. The computational details of the hair cell representation and Nerve Spike Density (NSD) can be studied from [6]. Here, $x[n]$ is a speech signal and $d[n]$ denotes the subband filtered signal obtained from the cochlear filterbank [18] (as shown in Fig. 3). Then, quadrature phase and subsequently, IF is estimated using QESA as shown in Algorithm 2. It can be observed in Fig. 2 that the proposed CFCCIF-QESA is able to capture more energy as compared to the CFCCIF-ESA feature set, for both the cases of genuine and spoofed signals.

Algorithm 2: The Estimation of IF Using Quadrature-Based Energy Separation Algorithm (QESA)

Input: Input: Subband filter output $d[n]$
Output: Output: IF
$d_z[n] = d[n] + j.HT\{d[n]\}$
/* Using Equation(8) */
$T_r[n] \leftarrow \text{TEO}\{\text{real}(d_z[n])\}$
$T_i[n] \leftarrow \text{TEO}\{\text{imag}(d_z[n])\}$
$\psi\{d_z[n]\} = T_r[n] + T_i[n]$
$IF \leftarrow Cos^{-1}\left[\frac{1-\psi\{d_z[n]-d_z[n-1]\}}{2\psi\{d_z[n]\}}\right]$

III. Experimental Setup

A. Dataset, Classifiers, and Features Used

Dataset: The dataset used is ReMASC, which is particularly developed for anti-spoofing on VAs [19]. The dataset was designed using four acoustic environments, namely, Outdoor Environment (Env A), Indoor Environment 1 (Env B), Indoor Environment 2 (Env C), and Vehicle Environment (Env D). The details of each of the environments can be studied from [19]. The environment-related experiments performed in this work are w.r.t. environment-dependent scenario, where training and testing have common acoustic environments.

GMM Classifier: The GMM classifier is trained using 512 mixture components in this work [20].

CNN Classifier: The architecture of the CNN classifier used comprises 6 convolution blocks and 2 Fully-Connected (FC) layers. Each convolution block is made of a 2-D convolution layer, which is followed by a batch normalization and max-pooling layer. Kernels of sizes 5×5 and 2×2 are taken in the convolution and max-pooling layers, respectively. The padding and stride is fixed as 1. The size of the input to the first convolution layer is 30×400. The batch size and learning rate are taken to be 32 and 0.0001, respectively. The loss function and the activation function used are cross-entropy loss, and Rectified Linear Unit (ReLU), respectively.

Features Used: This work uses the CQCC, CFCCIF-ESA, and the proposed CFCCIF-QESA feature sets. The parameters for CQCC are taken from [21]. Furthermore, we have taken 200 subband filters and 14 dimension for both of the feature vectors, where only static features are taken into consideration.

B. Performance Metrics:

Equal Error Rate (EER) and Score Level Fusion: EER estimated from the Log-Likelihood Ratio (LLR), is the threshold at which the Probability of False Alarm (P_{FA}) is *equal* to the Miss Probability (P_{Miss}). Here, the complementary information of each system is extracted using score-level

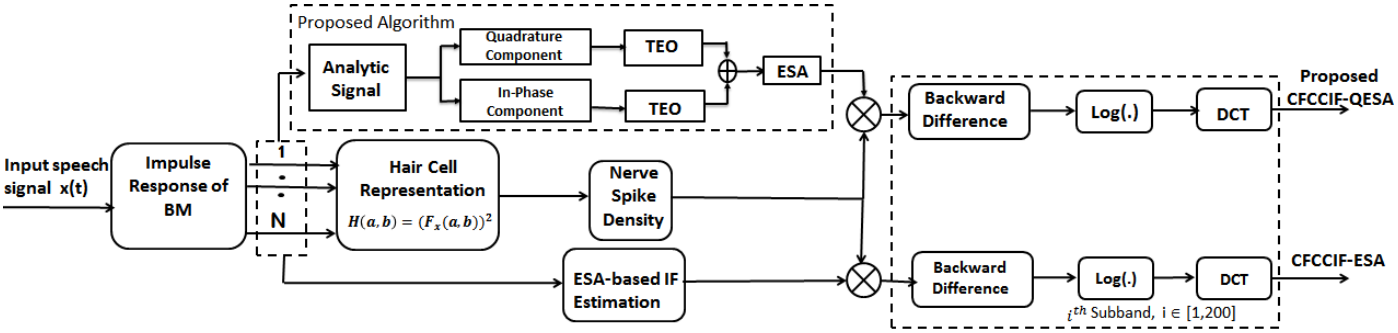

Fig. 3. The working of the proposed CFCCIF-QESA feature set, and the existing CFCCIF-ESA feature set.

fusion of LLR scores, which is computed as

$$LLR_{fused} = \alpha \cdot LLR_{feat1} + (1-\alpha) \cdot LLR_{feat2}, \alpha \in [0,1], \quad (9)$$

where LLR_{feat1} and LLR_{feat2} are LLR scores derived from feature set-1 and feature set-2, respectively.

Confusion Matrix-Based Metrics: Matthews Correlation Coefficient (MCC), F-measure, J-measure, Jaccard Index (JI), and Hamming Loss (HL) are some of the confusion matrix-based measures used to evaluate the performance of CFCCIF-QESA in this work. Out of these, a high value of MCC, F-measure, J-measure, and JI indicates better performance of the SSD system, whereas low value of HL indicates better performance of the SSD system. Details of each of these metrics can be studied from [22], [23], [24], [25].

IV. Experimental Results

Table I shows the environment-wise performance in terms of % EER. The environment-wise analysis shows the enhanced SSD capability of CFCCIF-QESA feature set over CFCCIF-ESA, particularly for the case of Env B, Env C, and Env D. Furthermore, for Env A, the performance of CFCCIF-ESA and CFCCIF-QESA is comparable. Next, Table II shows overall results in terms of %EER on GMM and CNN classifiers. It can be observed that in the case of classification by GMM, CFCCIF-QESA achieves overall EER of 28.71% on the Eval set, thereby achieving relative % decrease of 4.17% w.r.t. CFCCIF-ESA. Table III shows the confusion matrix-based performance measures. It can be observed that the proposed CFCCIF-QESA feature set shows improved performance as compared to the CFCCIF-ESA feature set. However, the CQCC feature set performs the best.

TABLE I
Environment-wise results in % EER using GMM as classifier

Feature Set	Environment-wise % EER			
	Env A	Env B	Env C	Env D
CQCC	22.58	48.48	43.45	14.47
CFCCIF-ESA	29.15	46.33	47.02	15.13
CFCCIF-QESA	29.22	45.53	46.81	12.75
CQCC ⊕ CFCCIF-ESA	**22.56**	46.33	43.45	12.42
CQCC ⊕ CFCCIF-QESA	22.58	**45.53**	**43.45**	**11.55**
⊕ indicates score-level fusion as per eq. (9)				

TABLE II
Results in %EER using GMM and CNN as classifiers

Feature Set	GMM		CNN	
	Dev	Eval	Dev	Eval
CQCC	19.94	22.56	15.36	25.33

Confusion Matrix-Based Performance Measures

	MCC	F1	J	JI	HL
CQCC	0.5735	0.8373	0.6006	0.64	0.34
CFCCIF-ESA	0.3543	0.8097	0.3638	0.71	0.28
CFCCIF-QESA	**0.3813**	**0.8212**	**0.4096**	**0.65**	**0.34**

A. Model-Level Comparison of CFCCIF-ESA vs. CFCCIF-QESA

KLD and Jensen–Shannon Divergence (JSD) have been used between the genuine and spoofed classes [26], to estimate the discriminative ability of our trained model. KLD and JSD are model-level information-theoretic measures to explore the discriminative abilities of the CFCCIF-ESA *vs.* CFCCIF-QESA feature sets. KLD is a measure to quantify how much two probability distribution functions (PDFs) differ from each other. It is mathematically defined as [27] If u and v are two

discrete PDFs, then KLD is :

$$KLD(u||v) = -\int_x u(x) \ln \left\{ \frac{v(x)}{u(x)} \right\} dx. \quad (10)$$

As it can be deduced from eq. (10), $KLD(u||v) \neq KLD(v||u)$ and thus, it is an asymmetric measure, and therefore, to deal with the asymmetry, a symmetric measure JSD is used, which is computed as [28]:

$$JSD(u||v) = \frac{1}{2}KLD(u||m) + \frac{1}{2}KLD(v||m), \quad (11)$$

where m is $\frac{1}{2}(a+b)$. A relatively high value of KLD and JSD indicates better discriminative ability of the model. Fig. 5 (a) shows the KLD between genuine and spoof GMMs, whereas Fig. 5 (b) shows the KLD between spoof and genuine GMMs, for both the feature sets. Here, it can be seen that the KLD between the GMMs of CFCCIF-QESA is *more* as compared to the KLD w.r.t. CFCCIF-ESA and hence, re-confirming the better discriminative ability of CFCCIF-QESA w.r.t. CFCCIF-ESA. Similar trend w.r.t. JSD can be seen in Fig. 5 (c). Furthermore, the differences in JSD, are shown in Fig. 5 (d), where the highest difference in JSD is observed at 64 number of GMM mixtures.

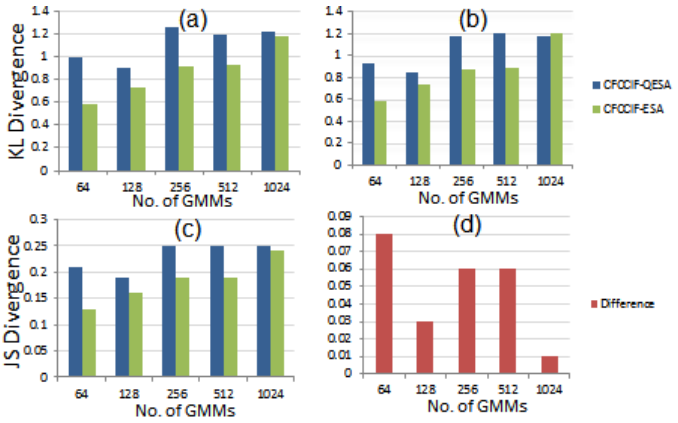

Fig. 5. Model-level measures: (a) $KLD(gen||sp)$, (b) $KLD(sp||gen)$, (c) $JSD(gen||sp)$, and (d) difference of JSD for varying number of GMM mixtures.

B. Analysis of Latency Period

In this study, we investigate the latency period for CFCCIF-QESA *w.r.t* CFCCIF-ESA feature set, which indicates how fast the SSD system is w.r.t. deployment in real-world applications. Latency is the performance evaluation in terms of %EER *w.r.t* different durations of speech segment in an utterance. Fig. 6 shows the latency analysis for the CFCCIF-ESA and the CFCCIF-QESA feature sets. The utterance duration ranges from 10 ms to 60 ms, with an interval of 10 ms. From Fig. 6, it is observed that CFCCIF-QESA shows relatively smaller latency as compared to the CFCCIF-ESA, i.e., CFCCIF-QESA reaches better performance than the CFCCIF-ESA even for a short duration (i.e., 10 ms) of speech. The low latency achieved by CFCCIF-QESA indicates that as compared to CFCCIF-ESA, CFCCIF-QESA has the ability to faster classification and thus, better suitability for practical system deployment.

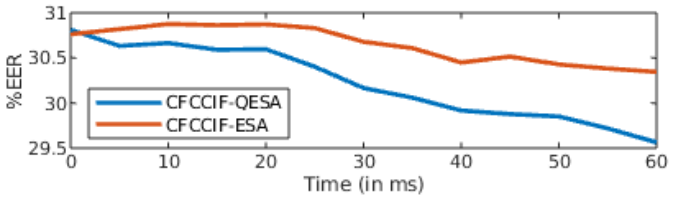

Fig. 6. Latency curves for CFCCIF-ESA *vs.* CFCCIF-QESA.

V. Summary and Conclusions

This paper investigated the importance of incorporating the quadrature phase for replay SSD w.r.t. VAs. An MI-based analysis is shown to highlight the importance of taking the quadrature phase. Furthermore, the extended definition of TEO is used to include the quadrature component in the signal. Given that the IF computation by the existing ESA method merits good time resolution of the TEO, the proposed QESA includes excellent time resolution, as well as the quadrature phase. With the similar approach as CFCCIF, except for the method of estimation of IF, a novel feature CFCCIF-QESA is designed. In this respect, the experiments are performed on the ReMASC dataset. Through our experiments, an improved performance is observed due to the inclusion of the quadrature phase using CFCCIF-QESA as compared to CFCCIF-ESA alone.

***Abstract*—In this paper, we introduce a Spoken Language Identification (SLI) system, which uses Linear Prediction (LP) residual, decomposed with linear filterbank and followed by log and Discrete Cosine Transform (DCT). This feature set is called Linear Frequency Residual Cepstral Coefficients (LFRCC). Mel Frequency Cepstral Coefficients (MFCC) and Linear Frequency Cepstral Coefficients (LFCC) were also extracted and kept as baseline features. The Attentive Time Delay Neural Network (Attentive - TDNN) was employed to evaluate the efficiency, relevancy, and sufficiency of said LFRCC features. For experiments, a computationally challenging VoxLingua107 dataset was used. From experiments, we achieved 9.22%, 7.8%, and 6.86% EER for MFCC, LFCC, and LFRCC, respectively. Significant improvements in accuracies and equal error rate (EER) were observed when comparing the performance of MFCC and LFCC with data fusion strategies. The feature-level fusion of MFCC and LFRCC resulted in a notable enhancement of 3.16%, 2.12%, and 1.16%, accuracies compared to other combinations. Moreover, each combination of feature sets in score-level fusion has outperformed LFRCC and baselines. This paper provides a significant study on how prosodic information provided by LP residual contributes to language-specific information. We present the pitch strength analysis to understand better the contribution of LP residual in capturing language-specific information.**

I. Introduction

The process of extracting information about one's spoken language is called Spoken Language Identification (SLI). At present, Human-Computer Interaction (HCI) applications are getting wide adoption and transcription. The services, such as Voice Assistance and Text Transcript from speech, are getting more popular, and many efforts are being made to be accessible to people of different languages. In such systems, SLI is sometimes used as a fundamental and primitive block, on top of which the architecture of such services is built [1]. *Language Line Interpreter* is one example of such service first provided by AT&T [2]. As technology reaches more people, it needs to be inclusive and robust; hence, developing such an SLI system is essential.

India is known to be multilingual, with different languages spoken in different parts of the country. In the past decade, researchers have shown an increased interest in developing SLI systems in the context of Indian languages [3]. Many recent studies use features that provide information about the vocal tract system as acoustics of speech that can be extracted using Mel Frequency Cepstral Coefficients (MFCC) [4], [5]. These acoustic features contain different phonemes for each language and, thus, help distinguish various languages. However, MFCC features are notoriously affected by noisy environments and changes in speaking style. The prosodic features, however, reveal the excitation source information such as Glottal Closing Instants (GCIs), stress, and intonations unaffected by noise or change in speaking style [6]. The direct use of Linear Prediction (LP) residual for SLI has been explored in [6]. In our paper, we parameterize the LP residual on a linear filterbank to extract the cepstral features, namely, LFRCC features. In addition, we also explore how different order of LP (in LFRCC) affects the performance of the SLI system.

Many researchers in the past have used methods that utilize acoustic features [7], [8]. They utilize statistical methods, such as Gaussian Mixture Models (GMM), Hidden Markov Models (HMM), i-Vector Universal Background Models (UBM), and Support Vector Machines (SVM). Further advancements in the field were made using deep learning architectures, such as Convolutional Neural Networks (CNN), due to their ability to capture local contexts [7]. Our study utilizes the Time Delay Neural Networks, which process sequential data better than CNN [9]; the paper introduced the TDNN, which is adopted in speech processing for their ability to capture the long temporal contexts [10], [11].

A. Related Work

The earlier studies reported in [12], [13] have applied LFRCC features to detect spoofed audio in the Automatic Speaker Verification system. Historically, LP residual represents the excitation source information of the speech, which contains the speaker's information and is helpful to differentiate speakers. In our paper, we exploit the LFRCC for the SLI. The LFRCC helps better preserve speech prosody, which leads to language-specific information. LFRCC contains pitch, rhythm, stress, and intonation, which are fundamental components of speech. Several methods have been explored in this area, such as [6], [8]. The method is computationally expensive in [6] as it utilizes an ASR system. In [8], they extract the pitch (fundamental frequency F_o) and energy of speech using the toolkit followed by mean normalization. In

979-8-3503-0067-3/23/$31.00 ©2023 IEEE

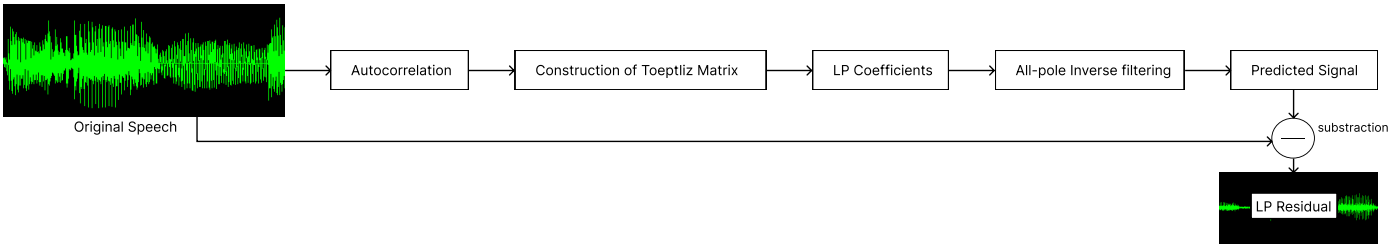

Fig. 1. Functional block diagram of extraction of LP residual.

our work, we gain such prosodic information from the LP residual and then parameterize it with a linear filterbank. The paper contributes the following.

- We study how the residual of the speech contributes to language-specific information, which helps in SLI.
- We show the visual inspection between the actual speech and residual speech
- For better understanding, we calculate the pitch strength and analyze the contribution of the LP residual in the context of syllable-timed vs. stress-timed languages
- As the SLI task should be robust against smaller speech segments, we show our model's latency period for the proposed LFRCC features.
- We also improved the results of the experiments with the help of two data-fusion strategies, namely, score-level and feature-level fusion.

The rest of the paper is organized as follows: Section II presents details of LP residual. Section III analyzes the pitch strength. Section IV shows the experimental setup used for the study. Section V presents the experimental results. Finally, section VI concludes the paper along with the potential future research directions.

II. Linear Prediction (LP) Residual

Linear prediction is a commonly employed and effective method for analyzing and predicting the behavior of dynamic systems. It involves using a specific number of previous samples to estimate the future sample, known as the prediction order, also referred to as the model order or LP order. Essentially, by setting the prediction order to p, the linear prediction filter utilizes p past samples to predict the next sample. The n^{th} sample of $X(n)$ can be predicted by a weighted summation of past samples, where a_p is the Linear Prediction Coefficient for k^{th} past sample [14]

$$\hat{X}(n) = -\sum_{k=1}^{p} a_k x(n-k) \ , \tag{1}$$

Calculating coefficients is an essential step in the linear prediction process required for the predicted signal. This involves several key procedures. Firstly, the autocorrelation between the preceding 'p' samples is computed. Subsequently, this auto-correlation information is utilized to generate a Toeplitz matrix. The linear predicted signal is ultimately obtained by applying the all-pole inverse filtering technique.

The error between the actual value $x(n)$ and the predicted signal $\tilde{x}(n)$ is given by,

$$e(n) = x(n) - \hat{x}(n) = x(n) + \sum_{k=1}^{p} a_k x(n-k) \ , \tag{2}$$

where $e(n)$ represents the residual component or linear prediction residual (LP residual). The LFRCC features, as discussed in the subsequent Section, are specifically designed to capture the spectral envelope of the excitation source. This characteristic has been widely recognized as a reliable indicator for various tasks, such as speaker identification and language recognition [6].

To ensure precise predictions, selecting an optimal prediction order is of utmost importance. Small orders may lead to inaccurate predictions as the model fails to capture essential signal features w.r.t dependencies in the sequence of samples of speech signals. Conversely, an excessively high LP order can result in overfitting of the model, resulting in a significant loss of generalized information and increased prediction errors.

The LP residual serves as a critical indicator of the performance of the LP model. A high energy value in the LP residual suggests that the model cannot accurately capture the fundamental characteristics of the signal, and a low energy value indicates that the linear prediction model has successfully captured the key features of the signal. This difference is clearly observed in figure 2, between (c) and (d). In many areas in the graph, high-energy horizontal striations are not present in the residual waveform. However, they are present in the original speech signal.

The LP residual comprises the signal portion not accounted for by the linear prediction model. Figure 1 shows the functional block diagram for extraction of LP residual.

A. Spectographic Analysis of LP Residual

Figure 2 shows the speech, LP residual, and their corresponding spectrogram.
It can be observed that LP residual discards the vocal tract shape as it flattens the spectral envelope. On the other hand, it also enhances the vocal fold vibration patterns atleast implicitly. These vocal fold vibrations contain several prosodic features, such as fundamental frequency (F_0), stress, and

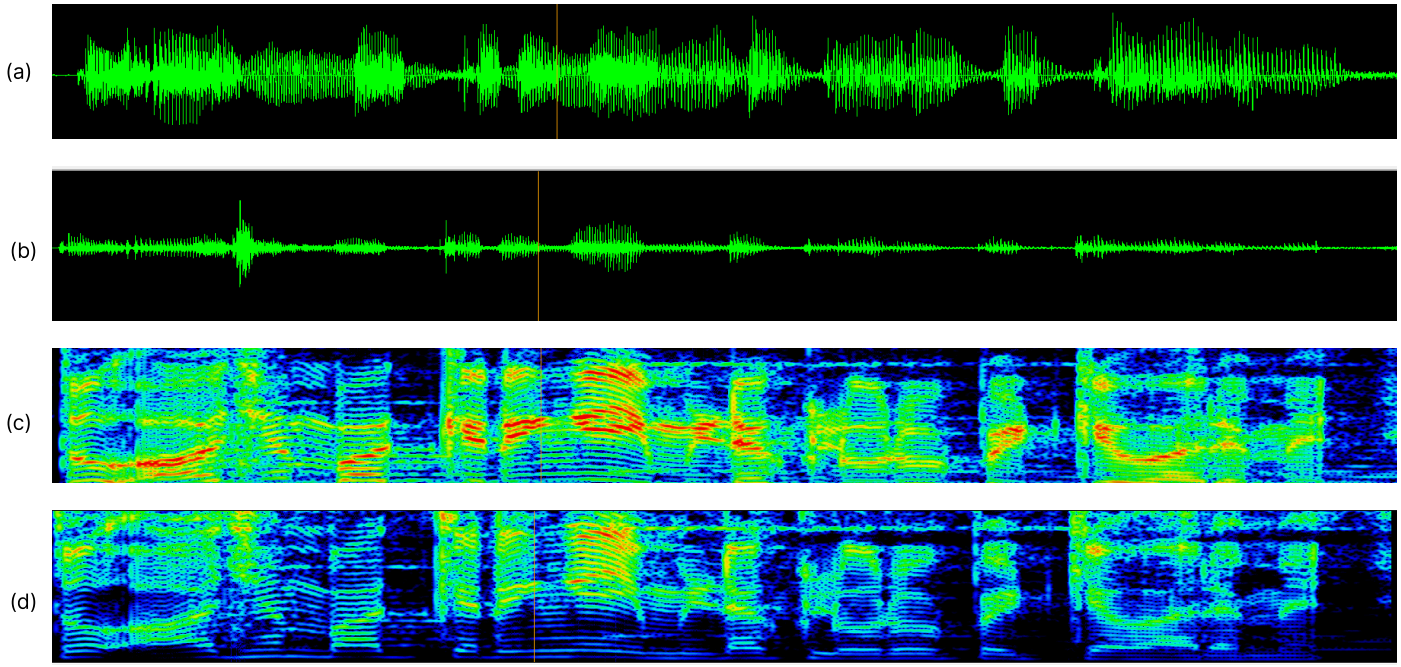

Fig. 2. (a) Speech waveform, (b) Corresponding LP residual speech for LP order 16, Spectrogram of (c) speech waveform shown in Fig 2(a) and (d) spectrogram of LP residual shown in Fig 2(b).

rhythm. These features depend on language structure and contain cues that can provide language-specific discriminatory information.

III. Analysis of Pitch Strength

We can define Pitch Strength as the distribution and preservation of pitch over the duration of the speech. The spoken languages can be divided into three groups: syllable-timed, stress-timed, and mora-timed [3], [5]. Languages such as English and Panjabi can be put into the stress-timed language category, where syllables have different lengths and maintain a rhythm. Indic languages such as Hindi, Bengali, and Tamil are said to be syllable-timed languages where the length of syllables is near-equal. This language structure depends on the prosodic information derived from the excitation source. To understand the prominence of the LP residual, we calculate the pitch strength of a syllable-timed and a stress-timed language using the auto-correlation method for LP Order 12 and LP Order 16. We can see changes in pitch strength for such in Figure 3. We can see that LP order 16 better preserves the speech structure, which significantly contributes to the language-specific information as prosodic information is mainly dependent on language [6]. We have calculated pitch strength explicitly for LP order 12 and LP order 16 because of the results (refer section V) for fine-tuning the prediction order p. In experiments, LP order 16 gives the highest accuracy, whereas LP order 12 gives the lowest.

IV. Experimental Setup

A. Dataset Used

Our study used the state-of-the-art, computationally challenging, and statistically prominent VoxLingua107 database [15]. The corpus is explicitly introduced for Spoken Language Recognition. The authors Valk J *et al.* use semi-random search phrases and scraped audio files from YouTube Videos, which were afterward validated using crowd-sourcing. The resulting database has an average of 62 hours of speech per language, totaling 107 languages. A total of 6628 hours of speech are provided in the database.

From the database, we use five language classes: English, Hindi, Bengali, Tamil, and Panjabi. Initially, the speech samples for each language class were divided by the groups of duration (i.e., sample duration less than 5 seconds, sample duration between 5 seconds and 10 seconds, sample duration between 10 seconds and 15 seconds, sample duration more than 15 seconds). Afterward, the same number of samples were taken from each duration class for each language. In one of those duration-wise groups for English, there were fewer speech samples ($<$ 1300), resulting in a total of 5132 speech samples. The detailed specifications of the database are provided in Table I. The resulting database was divided into 80% for training, 10% for validation (val set), and 10% for testing (test set).

B. Other Feature Sets Used

In our study, we have compared the performance of the LFRCC features with MFCC and LFCC features. The parametric details of these features can be found in Table II. Each

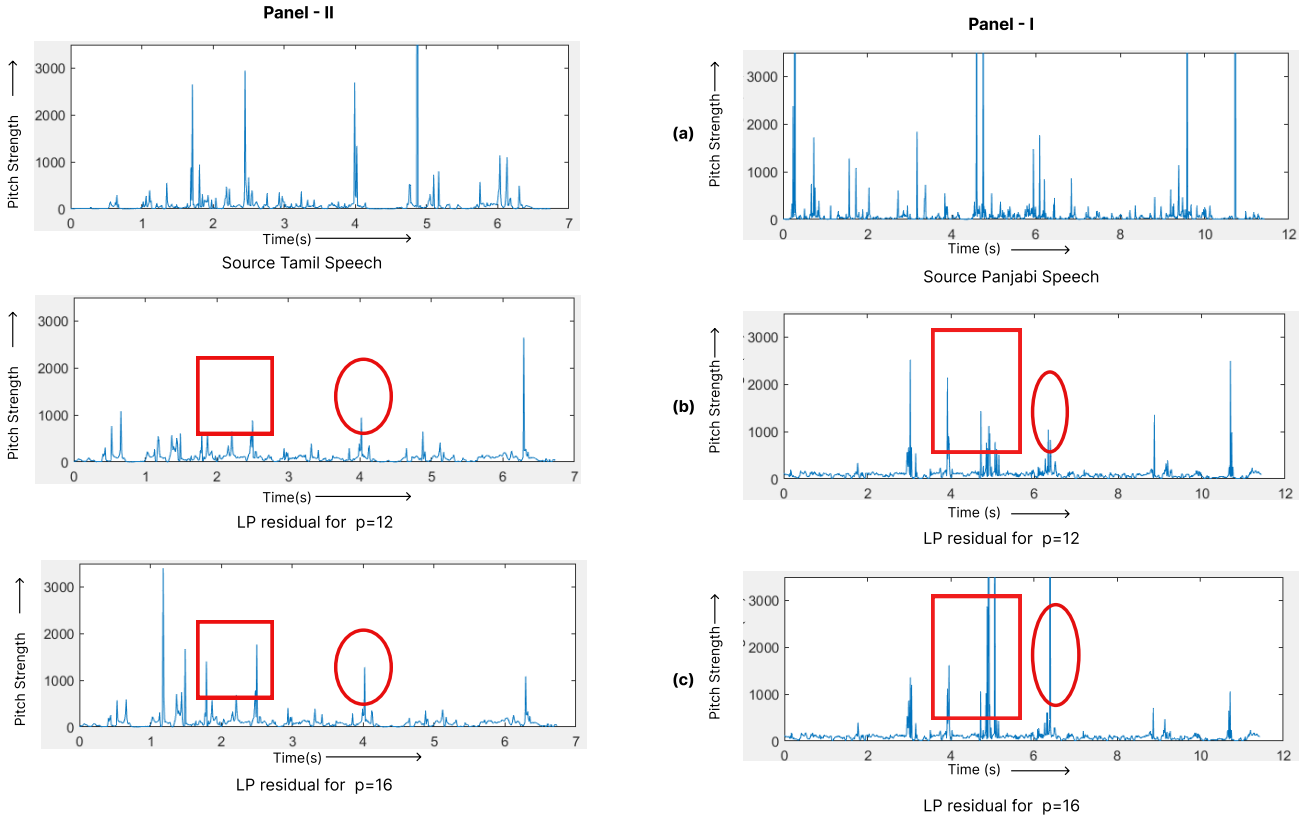

Fig. 3. Panel-I (a) shows the pitch strength of the stress-timed language, such as Panjabi; Panel-II (a) shows the pitch strength of syllable-timed languages, such as Tamil; Panel-I (b) and Panel-II (b) shows the pitch strength of the LP residual for p=12; Panel-I (c) and Panel-II (c) shows pitch strength of the LP residual for p=16

Dimension	13	13	13

feature vector was appended with 13 Δ and 13 $\Delta\Delta$ features to capture the temporal context. The extraction pipeline for each of these is provided in Figure 4. To gain LFRCC, first, the pre-emphasis is performed on the raw speech signal. Afterward, we obtain its LP residual using LP residual analysis. Then, the obtained speech is framed and windowed. Fast Fourier Transform is applied to gain their frequency representation on the framed and windowed speech. The resulting speech is afterward passed through a Linear filterbank of 40 subband filters. In the end, a log is applied to convert it to human perception. Discrete Cosine Transform decorrelates the filter bank coefficients and produces a set of cepstral coefficients. In MFCC, we do not pass the LP residual but instead pass the pre-emphasized speech and use the Mel Filterbank. In LFCC, similar to MFCC, we use the linear filterbank.

C. Model Architecture

The state-of-the-art TDNN [9] architecture is chosen for experimentation. The authors are inspired by the work [16]

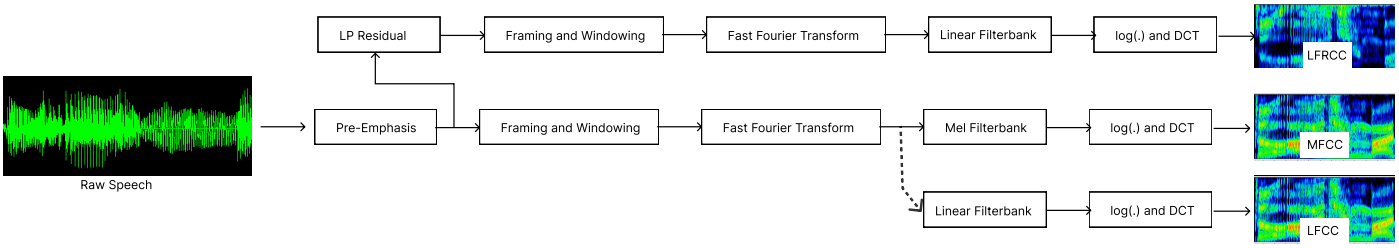

Fig. 4. Functional block diagram of extraction pipelines of various feature sets

and have performed the Attentive Statistics pooling in the TDNN network. The architecture closely follows the model described in [16]. The motivation behind using TDNN for our SLID is its ability to process sequential data and capture long temporal contexts [9]. The details of the TDNN layer used can be found in Table IV. We used TDNN layers and the classic attention and statistics pooling layers. The details of the classic attention module can be found in Table III. Table V provides an overview of the architecture, showcasing all the layers involved.

TABLE III
CLASSIC ATTENTION MODULE

Module Type	Classic Attention
Input Shape	(batch, seq_len, input_dim)
Output Shape	(batch, seq_len, input_dim)
Parameters	input_dim, embed_dim, attn_dropout
Linear Projection	Linear projection with kernel size (input_dim x embed_dim)
Activation	Tanh
Attention	Softmax along the sequence length dimension
	Output Shape: (batch, seq_len, input_dim)
Total Parameters: $(input_dim \times embed_dim) + embed_dim$	

TABLE IV
TIME DELAY NEURAL NETWORK (TDNN) MODULE

Module Type	TDNN
Input Shape	(batch, seq_len, input_dim)
Output Shape	(batch, new_seq_len, output_dim)
Parameters	context_size, stride, dilation, batch_norm, dropout_p
Linear Projection	Linear projection with kernel size (context_size x input_dim)
Activation	ReLU
Normalization	BatchNorm1d (if batch_norm=True)
Regularization	Dropout (if dropout_p > 0)
Forward pass	
1. Unfold input	Unfold input into smaller temporal contexts with kernel size (context_size x input_dim) **Output Shape:** (batch, output_dim*context_size, new_seq_len)
2. Linear projection	Compute output of shape (batch, new_seq_len, output_dim)
3. Activation	Apply ReLU activation
4. Regularization	Apply Dropout with probability dropout_p (if dropout_p > 0)
5. Normalization	Apply BatchNorm1d along the output dimension **Output Shape:** (batch, new_seq_len, output_dim)
Total Parameters	$(context_size * input_dim * output_dim) + output_dim$

1) Attentive Statistics Pooling: Statistics pooling is used in [17]. It calculates mean μ and standard deviation (second order statistics) σ over frames f_t *(t = 1,2,..T)*.

$$\boldsymbol{\mu} = \frac{1}{T}\sum_{t}^{T} \boldsymbol{f}_t \quad , \tag{3}$$

$$\boldsymbol{\sigma} = \sqrt{\frac{1}{T}\sum_{t}^{T} \boldsymbol{f}_t \odot \boldsymbol{f}_t - \boldsymbol{\mu} \odot \boldsymbol{\mu}} \quad , \tag{4}$$

TABLE V
TDNN NETWORK ARCHITECTURE

Layer	Kernel size	Filter size	Stride	Output shapes
TDNN	5	512	1	(batch_size, 512, 1)
TDNN	5	512	1	(batch_size, 512, 1)
TDNN	7	512	1	(batch_size, 512, 1)
TDNN	1	512	1	(batch_size, 512, 1)
TDNN	1	512	1	(batch_size, 512, 1)
Classic Attention	-	512	-	(batch_size, 512, 1)
Linear	1024	512	1	(batch_size, 512)
Attention statistics pooling				
Linear	512	512	1	(batch_size, 512)
Output	-	5	-	(batch_size, number of classes)

where $\odot$ is Hadamard product. Equations [3] and [4] are used to calculate the mean and standard deviation. This mean summarizes frame-level features and the standard deviation, which we believe encompasses various temporal variations in longer contexts associated with the language's characteristics other than the mean.

In language recognition tasks, certain frame-level features within an utterance may have significant prosodic and distinctive than others. To address this, studies such as [11] have incorporated attention mechanisms in their system to get weighted frame-level utterances. [18] applies this attention mechanism on TDNN for SLI.

An attention model Table III works with a Deep neural network to calculate a scalar score P_t for each frame-level feature

$$p_t = \boldsymbol{v}^T f\left(\boldsymbol{W}\boldsymbol{f}_t + \boldsymbol{b}\right) + k \quad , \tag{5}$$

where *f(.)* is tanh activation function. The score is further normalized using the *Softmax* function to obtain the normalized score N_t.

$$N_t = \frac{\exp\left(e_t\right)}{\sum_{\tau}^{T} \exp\left(e_\tau\right)} \, . \tag{6}$$

This score is then used as a weight in the pooling layer to calculate weighted mean vector $\tilde{\boldsymbol{\mu}}$.

$$\tilde{\boldsymbol{\mu}} = \sum_{t}^{T} N_t \boldsymbol{f}_t \, . \tag{7}$$

Instead of just mean, we have their weighted score, and we can use this to get the weighted standard deviation, $\tilde{\boldsymbol{\sigma}}$.

$$\tilde{\boldsymbol{\sigma}} = \sqrt{\sum_{t}^{T} N_t \boldsymbol{f}_t \odot \boldsymbol{f}_t - \tilde{\boldsymbol{\mu}} \odot \tilde{\boldsymbol{\mu}}} \quad , \tag{8}$$

where N_t is calculated by (6). By utilizing both statistics pooling and attention mechanisms, the weighted standard deviation method is thought to capture the long-term variations in feature representation while selecting frames based on their importance for language recognition.

V. Experimental Results

A. Effect of LP Order

This section presents the experimental results on classes described in Table I. According to the findings reported in [12], the study suggests an optimal range for LP orders is between 8 and 20. Experiments were conducted by generating the features for different LP orders and training them on the TDNN network. The outcomes of this experiment are depicted in Figure 5, which specifically showcases the results within the optimal LP order range; the results presented are on the test set. Upon analysis, it can be observed that the highest accuracy is achieved at LP order 16, and the lowest is achieved at LP order 12. This suggests that the LP order of 16 likely provides a more accurate representation than the other orders, leading to its superior performance. Based on the observed results, LP order 16 was taken for all subsequent experiments.

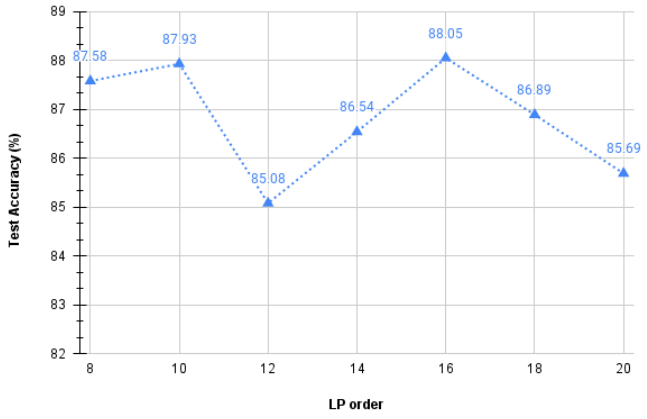

Fig. 5. Effect of LP order on SLI

B. Comparison Against Baselines

Further in the experiments, optimal LP order LFRCC features were compared against baselines MFCC and LFCC, trained on the Attentive-TDNN architecture described in Section IV. Table VI provides the results of LFRCC with the baselines. As LP residual in LFRCC preserves the speech harmonics better than any other features, it contributes to the language-specific information, which helps the model to learn discriminatory information between languages and, hence, outperforms the baselines.

C. Results of Score-Level Fusion

Score level fusion combines the scores of multiple features or classifiers to improve overall performance. We estimate log-likelihood scores of the features and fuse them by:

TABLE VI
Results in % of LFRCC against baselines for validation

Feature Set	Accuracy in %	EER in %
MFCC	85.23	9.22
LFCC	87.50	7.8
LFRCC	**89.01**	**6.86**

$$LLK_{\text{fused}} = \alpha LLK_{\text{feature 1}} + (1-\alpha) LLK_{\text{feature 2}} \quad (9)$$

where $LLK_{\text{feature 1}}$ is a log-likelihood score of MFCC or LFCC, whereas $LLK_{\text{feature 2}}$ represent the score of the LFRCC feature set. The fusion parameter (α) lies between $0 < \alpha < 1$ to decide the relative weight of scores. Equal Error Rate (EER) gauges the system's performance.

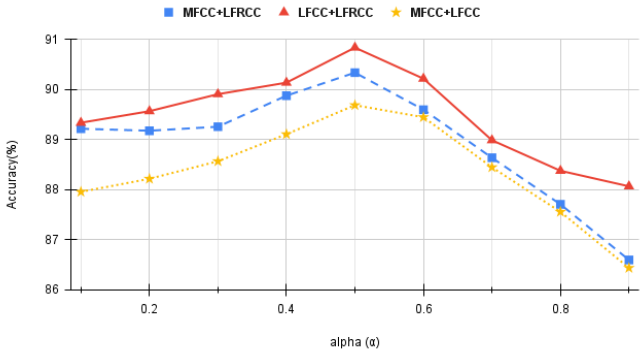

Fig. 6. Accuracy of score-level fusion in % for different α values

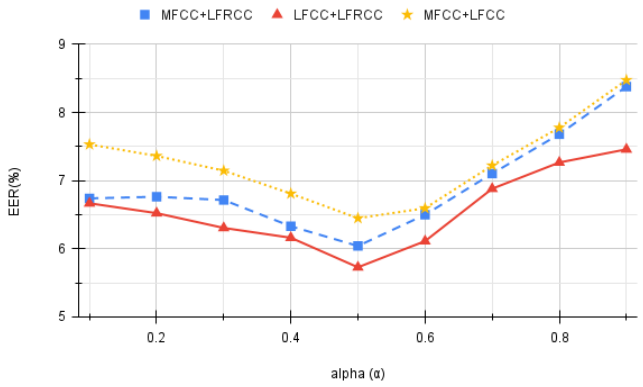

Fig. 7. EER of Score-Level Fusion in % for different α values

From Figure 6 and 7, we can see that the highest accuracy and lowest EER for each fusion have been achieved at 0.5 value.

D. Results of Feature-Level Fusion

In feature-level fusion, we fuse two different feature sets by stacking their coefficients. For this fusion, their time frames must match. Figure 8 shows the results of the feature-level

fusion over the Attentive-TDNN. We can see that the lowest EER has been achieved for the feature-level fusion of LFRCC LP order 16 and MFCC. As we know, MFCC provides the vocal-track information, and LFRCC provides the source information. Their fusion gives us information about the entire system from which speech is generated. Additionally, both of those contribute to discriminatory and essential language-specific information. Hence, it gives the best results.

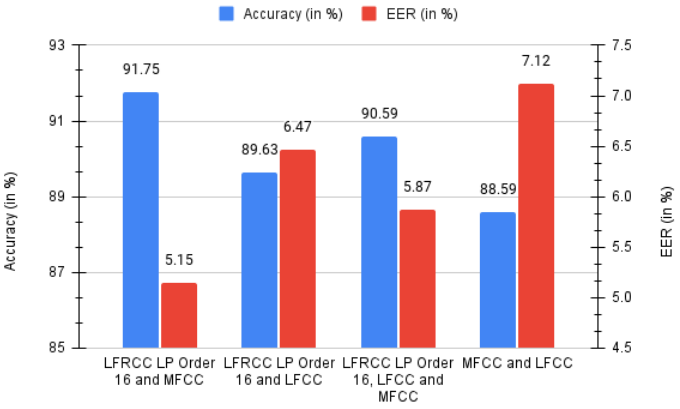

Fig. 8. Results of feature level Fusion

E. Analysis of Latency Period

In this study, computational and performance aspects of the LFRCC features against the baselines were also inspected using the latency period as shown in Figure 9. The latency period is calculated by % EER of classification for varying speech duration. Test segments of 1.5 seconds to 19.98 seconds were considered.

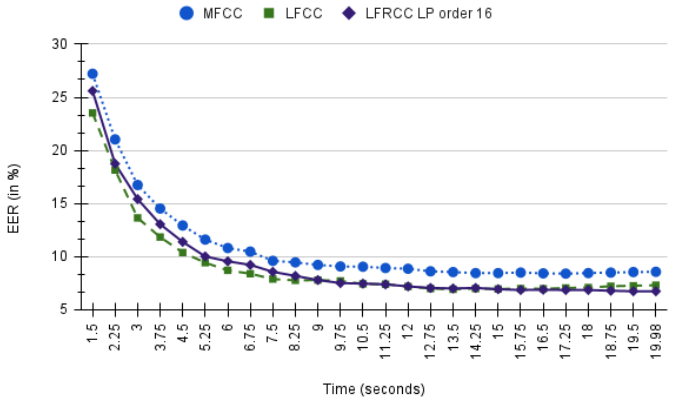

Fig. 9. Analysis of latency period for various feature sets

It can be observed from Fig 9 that the LFRCC features give the least % EER in classification. However, LFCC gives near-equal EER % classification as LFRCC for the speech duration < 9 seconds. In this context, the efficiency and credibility of the LFRCC features for practical use are clearly visible.

VI. Summary and Conclusion

The study presented an in-depth analysis of LFRCC features on SLI. To analyze the relevancy of LFRCC features, pitch strength analysis is introduced. The experiments are performed on the state-of-the-art VoxLingua107 database. To evaluate the performance, the attention pooling-based state-of-the-art TDNN architecture is employed. Additionally, MFCC and LFCC features were kept as baselines for a fair comparison. From the results, LFRCC features are observed to give better results than MFCC and LFCC. Additionally, score- and feature-level fusion improves the system's performance. The fusion of LFRCC with MFCC and LFCC has proven effective. Further, we also present the latency period analysis details on MFCC, LFCC, and LFRCC, which shows the potential of the LFRCC features for practical use. Future work will be directed towards including more language classes for the SLI. Additionally, in the future, the performance of the proposed LFRCC features can be evaluated in cross-database scenarios.

***Abstract*—We present an efficient training scheme for speaker verification (SV) networks in short-duration speech input scenarios. We analyze the effects of varying training lengths on SV performance, with a particular focus on short utterances. Despite the high demand for short-duration SV in real-world applications, state-of-the-art SV systems have primarily been evaluated on long utterances, and little research has been conducted on short-duration SV. By considering the innate characteristics of SV architectures and the performance discrepancies associated with varying training data lengths, we propose a training scheme that accounts for varying length conditions. We categorize speaker characteristics as coarse-grained and fine-grained features and demonstrate that training models to learn both features can result in length-robust speaker embeddings. Our proposed training scheme improves model performance by 28.7% and 37.9% in terms of equal error rate on short-duration speech scenarios compared to baseline models.**

***Index Terms*—Speaker verification, short utterance, training scheme**

I. INTRODUCTION

Speaker verification (SV) is the task of determining whether a speaker is enrolled in a given scenario based on a speech signal. It has applications in various fields, including security and personal authentication. With the development of neural networks, SV models have achieved excellent performance, making them applicable to many real-world scenarios [1]–[3].

Recently, there has been a rapid increase in demand for user-centered voice interface-based systems, such as wake-up words or short voice commands in AI speakers, mobile systems, or automatic driving systems [4], [5]. As a result, research on short-duration SV has gained attention, including the short-duration speaker verification (SDSV) challenge [6], [7] and various studies focusing on short-duration SV scenarios.

However, existing research on short-duration speaker verification primarily evaluates models on test utterances up to 8-second long, which is not short enough compared to the dominant speech datasets utilized for keyword spotting, which are approximately 1-second or shorter [8], [9]. Moreover, previous studies [10]–[13] that analyze short-duration speaker verification often rely on the revision of model architecture, complex fine-tuning processes or model fusion, leading to an increase in model parameters and computational complexity.

To address this issue, we investigate the inherent characteristics of short utterances compared to long utterances and define coarse- and fine-grained features and their relationship with the length of the utterance when extracting speaker embeddings. Accordingly, we propose an effective hard-condition training (HCT) scheme that does not require additional modules or model modification, allowing SV models to capture various speaker features on varying lengths. Thus, our proposed training scheme enables SV models to extract robust embeddings from utterances of varying lengths, particularly short utterances. Additionally, based on a deep analysis of two popular SV models, ECAPA-TDNN [3] and Thin ResNet34 [14], we propose adaptive training schemes tailored to their architectures and demonstrate the efficiency of the proposed training scheme. Our proposed training scheme improves the EER of ECAPA-TDNN and Thin ResNet34 by 28.7%, 37.9%, and 27.6%, 33.1% on two short utterance evaluation protocols, respectively.

Our contributions can be summarized as follows: 1) we propose an efficient training scheme for short utterance-driven neural SV systems by considering the characteristics of speaker-related features; 2) we redefine the type of speaker-related features depending on the length of input utterances, which is more suitable to categorize the behavior of short utterance-driven SV systems; 3) we perform a detailed analysis on the effect of the proposed training scheme and its contribution to performance improvement.

The remainder of this paper is organized as follows. Section II describes two main SV models and speaker-related features, and Section III explains our proposed training scheme along with a description of coarse-grained and fine-grained features. Section IV provides a detailed interpretation of the experiments and Section V offers an analysis of the results. Finally, we conclude the paper in Section VI.

II. BACKGROUND

A. Baseline speaker verification systems

As baseline systems for our experiments, we use the two famous deep learning models that utilize different neural network architectures, ECAPA-TDNN [3] and Thin ResNet34 [14]. Both models extract fixed-dimensional speaker embeddings from mel-spectrograms using a similar computational flow. However, they are different in the sense that ECAPA-TDNN maintains the resolution of time frames but Thin ResNet34 downsamples the input frames in the feature extraction process.

1) ECAPA-TDNN: ECAPA-TDNN and its variants [3], [15] are based on the time-delay neural network (TDNN) [16] and use 1-dimensional convolutional layers to estimate

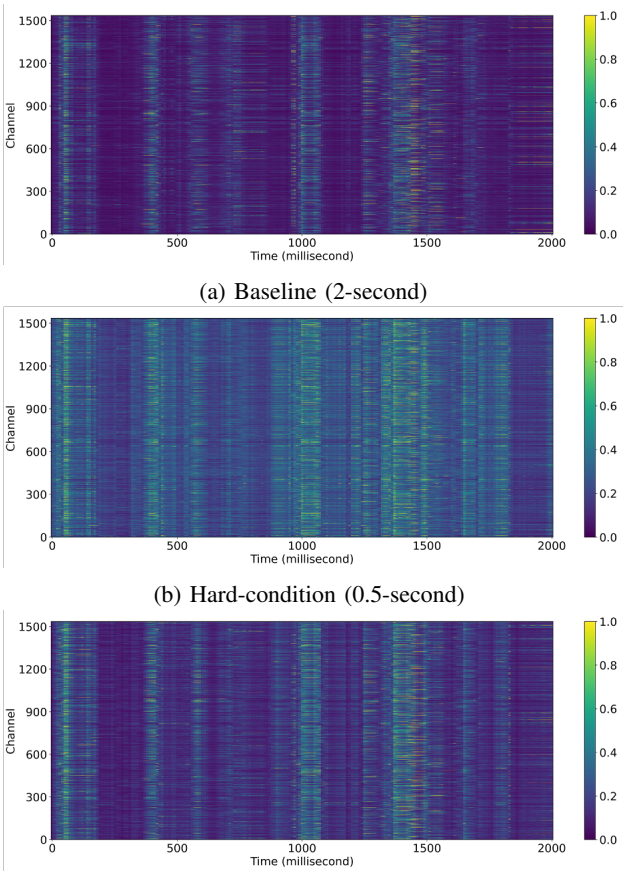
979-8-3503-0067-3/23/$31.00 ©2023 IEEE

speaker features. The frequency dimension of the input mel-spectrogram is first expanded to a large channel dimension using a 1-dimensional convolutional layer, and the hidden features maintain their dimension in both the channel and time axes up to the pooling layer. This time-preserving characteristic of ECAPA-TDNN enables the model to maintain the resolution of time-frames.

2) Thin ResNet34: ResNet systems utilize two-dimensional convolutional layers to process the features in both the time and frequency domains. Unlike ECAPA-TDNN, Thin ResNet34 down-samples the input mel-spectrogram by 1/4 and 1/8 in both the time and frequency axes, respectively.

B. Speaker-related features

Various speaker-related features have been studied for SV tasks. In [17], [18], such features are categorized into high-level and low-level features. High-level features include prosodic features such as pitch and energy, phonetic features such as pronunciation idiosyncrasies, and lexical features such as the preference of word usage, which reflect speaker habits and style not captured in the cepstral level. Low-level features, on the other hand, are related to the sound of a person's voice, such as cepstral features, acoustic correlates of timbre (color of sound), and features such as Mel-frequency cepstral coefficients (MFCC) [17].



III. Proposed Training Scheme

A. Fine and coarse-grained features

The categorization of high-level or low-level feature styles mentioned above is unsuitable for recent short-duration SV tasks because it is not easy to extract high-level features from the short length of utterances. Herein, taking the length of popular short-command datasets into account, we set 2-second as the reference length to define short or long utterances. In this paper, we categorize speaker-related features into fine-grained and coarse-grained features based on the length of the utterances used for training.

Coarse-grained feature: When an SV model is trained using long utterances ($\geq$2s), it tends to exploit the characteristics more coarsely. We denote features with large attention weights as coarse-grained features, as shown in Fig. 1a. SV models mainly focus on the time frames where more distinguishable speaker characteristics exist. In Fig. 2, the attention weight of the frames with high energy is larger compared to other frames. In other words, the SV models tend to concentrate on higher energy regions, rather than finding additional speaker characteristics existing between adjacent frames.

Fine-grained feature: In contrast, when the SV models are trained on short utterances, they tend to exploit utterances in a more fine-grained manner as shown in 1b. Disregarded frames or speaker characteristics in coarse-grained features are also thoroughly investigated. Detailed analysis of the two features will be discussed in Section V-A.

(a) Baseline (2-second)

(b) Hard-condition (0.5-second)

(c) Hard-condition mix III

Fig. 1: Channel-time attention plot of the attentive statistics pooling (ASP) layers from ECAPA-TDNN (identical 2-second inputs): (a) baseline (2-second) (b) hard-condition (0.5-second) (c) hard-condition mix III (2 and 0.5-second)

B. Hard-condition training

Conventional training schemes for SV systems [2], [3], [14] utilize a fixed length of relatively long utterances (2-3 second) for training, which allows the model to learn coarse-grained features. However, this approach causes the model to overlook fine-grained features during training, leading to poor performance in short-duration SV scenarios [19], [20]. Inherently, the amount of speaker-related features is less abundant in short utterances compared to long utterances, requiring a different approach for extracting speaker-related features. On the other hand, when the model is trained using only short utterances, it learns to extract fine-grained features; however, it shows poor performance [20] with respect to long utterance SV scenarios. To address this, we propose a hard-condition training scheme that trains the SV model using both short (0.5-1 second) and long (2-3 second) utterances to exploit both coarse and fine-grained features.

To fully utilize the essence of our proposed training scheme, it is essential to consider the neural architecture and processing flow of the SV model. For time-maintaining SV models such

as ECAPA-TDNN, using the training data with the combination of 0.5 and 2-second long utterances shows the best performance. However, for SV models having a temporal-downsampling architecture such as Thin ResNet34, training on short utterances lasting under 1-second is not recommended because the downsampling to time-frames affects the training of the SV model.

IV. Experiments

A. Database

We utilize the popular benchmark dataset, namely VoxCeleb 2 [21] dev set for training, and VoxCeleb 1 [22] test subset for evaluation. We do not perform any voice activity detection (VAD) or data augmentation schemes.

B. System Description

The baseline systems for our experiment are ECAPA-TDNN, Thin ResNet34, and Thin ResNet34-X. Thin ResNet34-X is a modified version of the original Thin ResNet34 that is designed to maintain the time frames. We modify the dimension of the output embedding to 512 for all systems. 80 and 40 dimension filterbank features extracted from a 25 ms frame window with a 10 ms shift are utilized as an input for ECAPA-TDNN and Thin ResNets, respectively. The network is trained with the Adam optimizer [23]. Initial learning rate and weight decay are set to 0.001 and 2e-5, respectively. For speaker loss, AAM-Softmax [24] with a margin of 0.3 and a scale of 30 is used for ECAPA-TDNN; alternatively, AM-Softmax [25] with a margin of 0.2 and a scale of 30 is utilized for Thin ResNet34 and Thin ResNet34-X.

C. Training Strategy

In this section, we explain the proposed training scheme in greater detail. For each training scheme, an equal number of audio samples are utilized for training.

- **Baseline-training**: Randomly crop 2-second-long utterances for training.
- **Hard-condition training-mix**: Randomly crop both long and short utterances for training.

D. Evaluation protocol

To effectively look into the efficiency of our proposed method, we simulated two different evaluation scenarios. And for both scenarios, we computed the cosine similarity between the speaker embeddings to obtain equal error rates (EERs), as done in [21]. No additional score normalization technique was used for evaluation. Details of each evaluation scenario are as follows:

Case 1 (Full-Short): We first simulated a scenario that the users enroll a relatively long speech, and test using a short utterance for convenience. For enrollment, we divide the full utterance into ten 3-second-long segments with regular intervals to extract the speaker embedding from each segment. For the short test utterance, we randomly crop x-second, which is identical to the length of the input short utterance, and extract a single embedding from it for the test. Subsequently, the cosine similarity scores between ten embeddings that are extracted from a full enrollment utterance and one embedding that is extracted from a short test utterance (10×1) are utilized to compute EERs.

Case 2 (Short-Short): To further improve user convenience, we also experimented with utilizing a short utterance for both enrollment and test. For both enrollment and test, we randomly crop x-second from each utterance and extract a single embedding.

To eliminate the randomness caused by randomly cropping short segment speech, we repeated ten trials for each experiment with identical random seed sets and averaged the resultant EERs to obtain the final score.

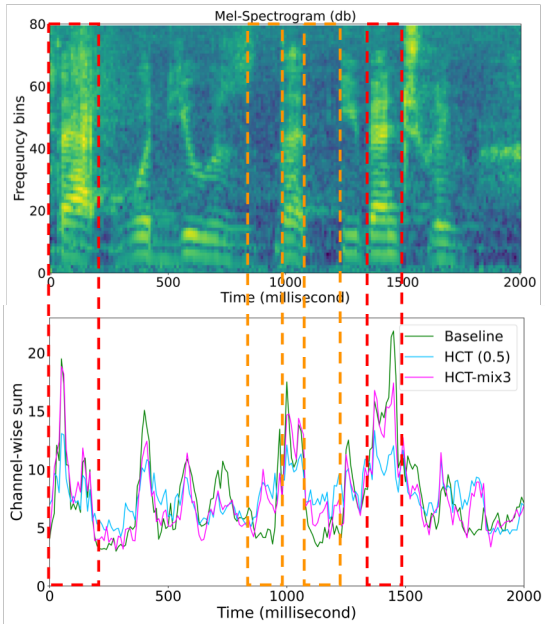


Fig. 2: Mel-spectrogram (upper) and corresponding channel-wise summation of attention weights obtained from ASP layers (lower).

V. Result and Analysis

A. Coarse-grained and fine-grained features

To analyze the coarse-grained and fine-grained features learned using different training schemes, we plot the channel-wise attention weights taken from the attentive statistic pooling layer in Fig. 1a. From the figure, we observed that the attention weights obtained from the baseline model selectively concentrate on certain time frames, whereas those of the model trained only with 0.5-second (Fig. 1b) focus on each frame in a more fine-grained manner. The HCT-mix III trained model (Fig. 1c) shows the intermediate behavior between the two.

To compare the characteristics of these features in detail, we plot the channel-wise sum of the three attentions in Fig. 1 along with the corresponding mel-spectrogram in Fig. 2. It is shown that the baseline model gives more weight to the voiced regions with high energy. On the other hand, the model

TABLE I: Performance was evaluated using the VoxCeleb1-O testset. We averaged ten evaluations for each experiment. HCT (0.5 sec) and HCT (1 sec) denote models trained with only 0.5 and 1-second, respectively. HCT-mix I, II, III denote training with a combination of [0.5, 1], [1, 2], and [0.5, 2] second with a 1:1 ratio, respectively.

Model	Training Scheme	Evaluation Protocol					
		Case 1 : Full-Short (EER)↓			Case 2 : Short-Short (EER)↓

trained with hard conditioning utilizes every time frame with a similar weight or exploits an inter-frame relationship. To be specific, the red dashed box highlights the time frames with high energy, indicating that the baseline model tends to give higher attention to those frames. By contrast, the attention weights in the orange dashed box indicate that our proposed training scheme also considers those time frames that are less regarded by the baseline. This characteristic of the hard-condition trained model indicates the success of capturing both coarse-grained and fine-grained features.

B. Effect of hard-condition training

Table I shows that using short utterances for training is crucial for achieving good performance on short utterances in the evaluation protocol of Case 2. The best-performing models in this scenario are those trained using either 0.5-second only or a mix of 0.5-second and longer utterances. For instance, the ECAPA-TDNN model trained using HCT (0.5-second) achieves an EER of 7.450% on short utterances, which is the best result in this evaluation protocol. Given the limited amount of information available in short utterances, fine-grained features are essential for extracting speaker embedding. The experiment result of ECAPA-TDNN on HCT (1 sec) and HCT (0.5 sec) further emphasizes the importance of fine-grained features for short utterances. HCT (0.5 sec) shows a superior result over HCT (1 sec) even in 1-second where the train-test condition matches.

However, simply focusing on the fine-grained features during training is not enough to achieve good performance on long utterances in the evaluation protocol of Case 1. Considering the length discrepancy between the enrollment utterance and the test utterance, speaker embedding should be robust to the length of the utterance. Thus, the SV models should consider both coarse-grained and fine-grained features when extracting speaker embeddings. In Table I, HCT-mix trained models show better performance compared baseline model in general. Specifically, The ECAPA-TDNN model trained using HCT-mix III, which utilizes both 0.5 and 2-second for training, achieves the best performance on this evaluation protocol. This model achieves an EER of 4.064% on 1-second utterances, which is a 28.7% improvement over the baseline result, as shown in Fig. 3. In summary, these results demonstrate the importance of using short utterances for training to learn fine-grained features, as well as the need to use longer utterances to learn coarse-grained features.

C. Analysis on model architecture

*1) **ECAPA-TDNN vs Thin ResNet34**:* In general, the experimental results obtained with Thin ResNet34 and ECAPA-TDNN show similar trends. As shown in Table I, Thin ResNet34 trained using HCT-mix I, II and III resulted in promising performance on both evaluation scenarios compared to simply using a single fixed length for training. In Fig. 3, both ECAPA-TDNN and Thin ResNet34 have shown significant improvement, and the trends of relative improvement are also similar for both models. However, the lower relative improvement on 0.5-second utterances is due to using the downsampling processing of Thin ResNet34, as mentioned in Section II. The temporal downsampling characteristic of Thin ResNet34 may distract the model from learning speaker-

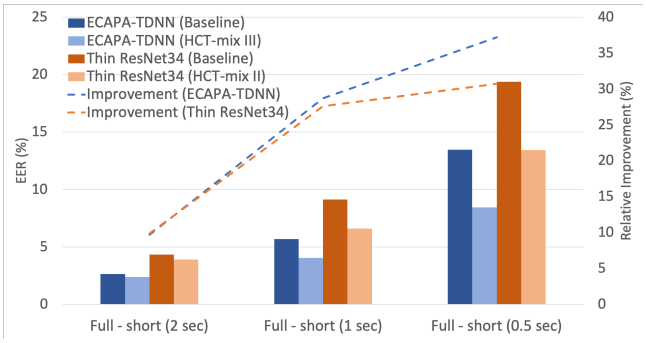

Fig. 3: SV performance evaluation protocol of Case 1 on two baseline models with relative improvement

related features on short training utterances. For example, in the case of HCT (0.5-second) for Thin ResNet34, the time frames are downsampled from 50 to 16 frames, resulting in poor performance on the evaluation protocol of Case 1.

*2) **Thin ResNet34 and Thin ResNet34-X**:* In Table I, the Thin ResNet34-X shows similar trends but superior results compared to the original Thin ResNet34 in all evaluation scenarios. This improvement is due to maintaining the length of time frames so that the model is capable for learning fine-grained features. Compared to the original Thin ResNet34, Thin ResNet34-X can process the hidden features in a more fine-grained manner and extract more detailed speaker-related features. Therefore, the result of Thin ResNet34-X resembles that of ECAPA-TDNN than the original Thin ResNet34, showing the best performance when trained using HCT-mix III.

VI. Conclusion

We thoroughly analyzed the varying feature characteristics of the speaker verification (SV) system depending on the length of training utterances. Pointing out the different speaker features on varying audio lengths and model characteristics, we emphasize the importance of using both the coarse-grained and fine-grained features for SV. By training the SV model with long and short utterances together, SV models are forced to focus not only on the coarse-grained features but also on the fine-grained features, resulting in much higher performance. As a result, our training scheme has achieved a relative improvement of 28.7%, 27.6% on the evaluation protocol of case 1 and 37.9%, 33.1% on case 2 for ECAPA-TDNN and Thin ResNet34, respectively. For future research, we plan to develop a new training framework to explore methods to effectively combine SV and keyword spotting systems.

Adversarial Robustness of Mel Based Speaker Recognition Systems

Ritu Srivastava Saiteja Kosgi Sarath Sivaprasad Neha Sahipjohn Vineet Gandhi

***Abstract*—Convolutional neural networks (CNN) applied to Mel spectrograms now have a dominant presence in the landscape of speaker recognition systems. Correspondingly, it is also important to evaluate their robustness to adversarial attacks that remains not thoroughly explored for end-to-end trained CNNs for speaker recognition. Our work addresses this gap and investigates variations of the iterative Fast Gradient Sign Method (FGSM) to perform adversarial attacks. We observe that a vanilla iterative FGSM can flip the identity of each speaker sample to that of every other speaker in the LibriSpeech dataset. Furthermore, we propose adversarial attacks specific to Mel spectrogram features by (a) limiting the number of pixels attacked, (b) restricting changes to specific frequency bands, (c) restricting changes to particular time duration, and (d) using a substitute model to craft the adversarial sample. Using thorough qualitative and quantitative results, we demonstrate the fragility and non-intuitive nature of the current CNN-based speaker recognition systems, where the predicted speaker identities can be flipped without any perceptible changes in the audio. The samples are available at "https://advdemo.github.io/speech/"**

I. Introduction

Convolutional neural networks have matured over the last decade and continue to show performance gains on numerous tasks [1]. However, one major concern with CNN models is that they are susceptible to small input perturbations. Previous works have shown that CNN models can be tricked to misclassify highly confident predictions by adding a small additive targeted noise to the input image [2]. Consequently, adversarial robustness has been an area of interest for deep learning research in recent years, and the robustness to adversarial attacks has become an important factor in evaluating systems. The study of adversarial robustness is specifically important in applications where the cost of misclassification is high, for example, biometric authentication. With access to the trained model (white-box attacks) or otherwise by multiple trials, an attacker can compute the gradients or its numerical approximation to break the authentication systems. To this extent, distortion-less adversarial attacks are malicious to authentication systems as they make it difficult to debug and trace the attack.

Speech signals are a popular modality for biometric authentication. Various features and modeling techniques have been proposed over the years to enhance the performance of Speaker Recognition (SR) systems. Earlier approaches relied on classifiers learned on top of common feature representations like i-vector [3] and x-vector [4]. The seminal work by Nagrani et al. [5] shows that an end-to-end CNN, when applied to raw spectrograms, gives promising results. Using Mel spectrograms as the input also circumvents the need to pre-process the audio data. Further, this approach of learning CNNs on Mel spectrograms has found success in numerous downstream tasks like automatic speech recognition, speaker recognition and style capture in speech generation.

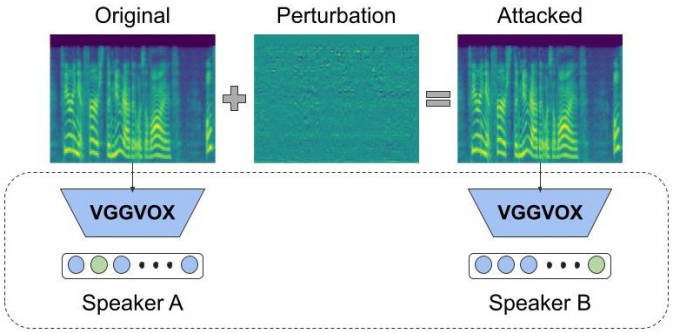

Fig. 1. Adversarial attack on Speaker Recognition Systems

Speaker recognition, among other applications, requires systems to be secure from malicious attacks and have been tested for their robustness to such attacks. Traditional testing methods focused on spoofing attacks like replaying recorded speech [6], mimicking human voice [7] and use of synthesized speech [8]. More recent forms of attacks attempt to fool models by supplying deceptive or adversarial input *i.e.*, to generate acoustic utterances that sound as one speaker (say speaker A) to the human ear but are classified by the system as another speaker (see Figure 1 for an illustration). Adversarial attacks on speaker identification systems have been studied for i-vector and x-vector systems, relying on Mel frequency cepstrum or MFCC features [9]–[11]. The adversarial robustness of current state-of-the-art, end-to-end CNN models on raw Mel spectrograms remains largely unexplored.

Our work bridges this gap and studies the adversarial robustness of end-to-end trained CNN models for speaker recognition. We perform our experiments on LibriSpeech dataset [12] using variants of Fast Gradient Sign Method (FGSM) [13] on the VGGVox architecture [5]. Our findings show that with limited change in the input pixels of Mel spectrogram, a vanilla iterative FGSM attack can change the prediction of each speaker sample to every other label in the dataset. We observe that the corresponding distortion in audio is proportional to the number of gradient updates in FGSM. We also evaluate the

979-8-3503-0067-3/23/$31.00 ©2023 IEEE

efficacy of adversarial attacks constrained to specific regions of the spectrogram. Predicted speaker labels can be flipped by limiting changes to a small time band, a small frequency band, or a few pixels (as illustrated in Figure 2). We also use a substitute model to compute the adversarial sample to show that the attack can be performed with minimal assumptions on the target model.

FGSM-like attacks become infeasible in the absence of access to the entire model. This mitigates the risk of adversarial attacks in many in-house developed real-world systems. However, since most models are trained using transfer learning, it is often the case that these backbone models are available in public. We show that adversarial samples can be crafted using a different model with the same backbone. Overall, our work makes the following contributions:

- We explore the robustness of VGGVox architecture to FGSM attack and show that it can change the prediction of a sample to any other class in the given dataset.
- We propose three constrained FGSM attacks and show that predictions can be altered with minimal changes to spectrogram that are mostly imperceptible to the human ear.
- We evaluate the performance of models when the adversarial samples are crafted without access to the actual model but using a different model with the same backbone.
- We present qualitative and quantitative results to demonstrate the efficacy of proposed methods with ablation studies analyzing the role of the number of iterations of FGSM, number of pixels, and different time/frequency bands.

II. Related Work

Early research in SR systems devoted significant resources to the study of crafting the suitable feature set for speaker recognition [14] [15]. In the pre-deep learning era, MFCC-like features were mostly used in speaker recognition systems. Classifiers using i-vectors [3], a low-dimensional speaker and channel-dependent space learned using factor analysis, achieved state-of-the-art results in SR. Subsequently, methods based on x-vector features [4] learned from deep networks outperformed earlier models [16]. x-vectors are extracted from a deep neural network trained for speaker classification [4].

Nagrani et al.[5] proposed modeling the SR system as an end-to-end convolutional network over 2D representation of Mel frequency intensities. End-to-end CNN models gave promising results and offer a methodically simple solution to SR. Since [5], using convolutions on Mel features has become popular in many speech and audio based tasks like audio tagging [17], acoustic scene classification [18], speech emotion classification [19], sound event detection [20], and style capture in speech generation [21].

Since CNNs are known to be susceptible to adversarial attack in image classification literature [2], it is natural to ask; how robust are speech and audio systems built with convolutions on spectrograms to adversarial attacks? Especially those like SR that are used in user authentication systems.

Different speaker recognition methods have been studied for their adversarial robustness. A detailed survey of existing research on the robustness of speaker recognition systems is presented in [22]. Li et al. [9] study the vulnerability of x-vector based SR system by developing adversarial samples that remain effective while being played over-the-air. This is achieved by modeling the air channel using the estimated room impulse response, then convolving it with the input, followed by FGSM. Wang et al. [11] also shows that x-vector based SR system can change speakers across genders with no perceptible distortion in the input. Chen et al. [10] studies the robustness of SR systems to adversarial attacks to understand their security weakness in the practical black-box setting. They propose an adversarial attack and explore its efficacy on i-vector based systems, GMM-UBM systems, and x-vector based systems.

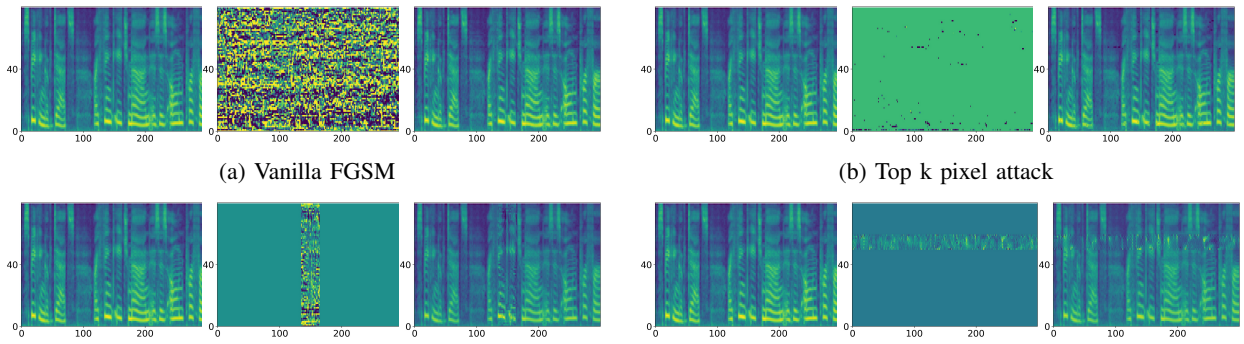
The prior art to be seen as closest to our work is [11], which proposed an imperceptible white-box psychoacoustics-based method to attack an x-vector model. We study the adversarial robustness of speaker recognition systems, which are end-to-end CNN based models that take raw spectrogram as input with softmax layer to predict the speaker label. Our work focuses on making a comprehensive analysis by restricting the attacks in time and frequency bands, limiting the number of editable pixels, and crafting adversarial samples by making minimal assumptions about the model.

III. Method

Adversarial samples are inputs explicitly designed to confuse or mislead a neural network, resulting in the misclassification of the sample. FGSM uses the gradients of the neural network to create the adversarial example. This method is known to achieve the attack through imperceptible additive perturbations.

Given an input spectrogram $\mathbf{x}$ belonging to y, we wish to generate $\tilde{\mathbf{x}} \sim \mathbf{x} + \eta$ with perturbation η that model will misclassify into y^*. FGSM generates perturbations using gradients of the loss J at $\mathbf{x}$ using y^* to generate $\tilde{\mathbf{x}}$ as,

$$\tilde{\mathbf{x}} = \mathbf{x} + \epsilon \operatorname{sign}\left(\nabla_{\mathbf{x}} J(\mathbf{x}, y^*; \theta)\right) \tag{1}$$



where θ is the network parameter and ϵ is a hyper-parameter controlling magnitude of the perturbation. We apply FGSM iteratively in our experiments with initialization $\tilde{\mathbf{x}}_0 = \mathbf{x}$ as,

$$\tilde{\mathbf{x}}_t = \tilde{\mathbf{x}}_{t-1} + \epsilon \operatorname{sign}\left(\nabla_{\tilde{\mathbf{x}}_{t-1}} J(\tilde{\mathbf{x}}_{t-1}, y^*; \theta)\right) \tag{2}$$

and terminating the loop when the predicted class label is flipped to the desired $y^* = \operatorname{argmax}_y f(\tilde{\mathbf{x}}^*; \theta)$. We propose variants of iterative FGSM , all of which can be considered as different masks applied on the gradient before applying on $\tilde{\mathbf{x}}$. The masked variations is,

$$\tilde{\mathbf{x}}_t = \tilde{\mathbf{x}}_{t-1} + \epsilon \left(\mathbf{M}_{t-1} \odot \operatorname{sign}\left(\nabla_{\tilde{\mathbf{x}}_{t-1}} J(\tilde{\mathbf{x}}_{t-1}, y^*; \theta)\right)\right) \tag{3}$$

where $\mathbf{M}_{t-1}$ is the binary mask and $\odot$ represents element-wise product. We evaluate three different masks in this work.

(a) Vanilla FGSM

(b) Top k pixel attack

(c) Selected time band

(d) Selected frequency band

Fig. 2. Figure shows the effect of the four attacks used on the spectrogram. For each experiment the three spectrograms in the figure shows: the original spectrogram, the computed perturbation and the attacked spectrogram respectively

Top-k pixels: In this variant, we restrict perturbations to a fraction k of all pixels in the spectrogram $\tilde{\mathbf{x}}$ with the largest gradient magnitude in the first iteration. Mask $[\mathbf{M}]_{ij} = 1$ is computed at the first iteration consisting of pixels with magnitude of the corresponding entry in gradient $[\text{abs}(\nabla_{\tilde{\mathbf{x}}} J(\tilde{\mathbf{x}}, y^*))]_{ij} > \tau$ and $[\ \cdot\ ]_{ij}$ is indexing operation into (i, j) element. Threshold τ is chosen such that $k * N$ pixels are allowed to be altered. N is the total number of pixels. In subsequent iterations, only pixels corresponding to $[\mathbf{M}]$ are updated. The resulting mask satisfies $\mathbf{1}^\top \mathbf{M} \mathbf{1} = k * N$ where $\mathbf{1}$ is a vector of ones.

Frequency band: In this case, we allow the attack only on a chosen frequency band of the spectrogram. The frequency band is a horizontal strip in the spectrogram, as shown in Figure 2(c). The mask here is a fixed matrix across all iterations set to $[\mathbf{M}_t]_{ij} = 1$ only for $i \in [\tilde{\nu} - \nu/2, \tilde{\nu} + \nu/2]$ for a chosen frequency $\tilde{\nu}$ and window length of ν around it. We report experiments for various frequencies $\tilde{\nu}$.

Time period: Similar to the frequency band restriction, we consider limiting attack to a specific time span of the speech signal. This corresponds to constraining the attack to a vertical strip of the spectrogram and the mask is fixed across all iterations to $[\mathbf{M}_t]_{ij} = 1$ only for $j \in [\tilde{\rho} - \rho/2, \tilde{\rho} + \rho/2]$ for a chosen time $\tilde{\rho}$ with window ρ.

Using a substitute model: We evaluate the adversarial robustness of SR models in two different scenarios. We train a model(M_1) on N speakers and craft an adversarial sample using this. The target model (M_2) has n speakers, such that $n << N$. M_2 is fine-tuned with the backbone of M_1. In the first setting, the two sets of speakers used to train source model M_1 and target model M_2 are mutually exclusive and exhaustive. In the second setting, one of the speakers is common between the training sets of M_1 and M_2.

IV. Experiments

We experiment with a CNN speaker recognition model as in [5] trained on LibriSpeech [12] corpus. While the complete LibriSpeech corpus consists of about 1000 hours of speech from 2400 speakers, we use only a clean subset of 360 hours comprising 927 speakers. We sample the waveforms at 22KHZ and convert them into Mel spectrograms with 80 Mel channels by short-time Fourier transform using a Hamming window of length 1024 and hop length of 256. We train the speaker discriminator with a simple training strategy using no augmentation.

We perform our FGSM attacks using the aforementioned trained model. For all our experiments, we compare the audio generated from the attacked Mel spectrogram with the audio generated from the original spectrogram using MelGan [23]. Also, we limit the maximum number of perturbation iterations allowed to 5000. In other words, we label the adversarial attack unsuccessful if the network prediction is not converted to the target label within 5000 updates.

We perform a human survey to qualitatively measure the distortion in the audio generated by the attacked Mel spectrogram. For each of our four experiments, we ask fifty users to evaluate twenty pairs of audio each. Each pair constitutes one audio generated from the original Mel spectrogram and the other generated from the attacked Mel spectrogram. We ask the participants to rate the distortion in the attacked audio compared to the former on a Likert scale of three; with zero corresponding to no distortion at all, one for minor distortions, and two for significant distortions. We report the Mean Opinion Score (MOS) of the participants for all four experiments.

Vanilla iterative attack vs. Top-k pixel attack: In the first experiment, we apply the vanilla iterative FGSM attack described in Equation 2 on one random sample of each 927 speakers. Each sample is perturbed to change the prediction to that of every other speaker in the dataset. We report the average number of iterations taken to change the label for each speaker. In the second experiment, we evaluate the efficacy of the top-k pixels attack strategy for two distinct values, $k = 1.25\%$ and $k = 2.5\%$. We measure the Perceptual Evaluation of Speech Quality (PESQ), Signal to Noise Ratio (SNR), and Mean Square Error (MSE) between the audio from the attacked Mel spectrogram and the audio from the original spectrogram for quantitative evaluation.

Frequency band and time period attack: We choose 50 speakers from the dataset for experiments with restricted

frequency and time band adversarial attack. We use stratified sampling to include same number of male and female speakers for this subset. We attack a sample from each speaker from this subset with all other speakers as target label. We choose a mask of width 1 KHz and evaluate the attack on ten such non-overlapping positions. Frequency values $\tilde{\nu}$ are chosen such that the 10 non-overlapping windows span the entire width of the spectrogram ranging from 0-8 KHz. In the fourth experiment, we evaluate the efficacy of time segment based attacks. We evaluate time segment attack by choosing a mask of width ρ as small as 2 frames to a maximum of 30 frames. We position the mask at the spectrogram's beginning, middle, and end.

Using a substitute model: We perform two experiments to evaluate the adversarial robustness of models when the adversarial sample is crafted using a substitute model. In the first experiment, we show the transferability of attacks using samples crafted from a model trained on a different set of labels. This experiment evaluates the adversarial robustness when a model with the same backbone is publicly available for crafting adversarial samples. We use 800 speakers to train the source model (M_1) and 121 different speakers to train the target model (M_2). M_2 is initialized with the backbone of M_1, and the backbone weights are frozen during the training. There are no common speaker identities between the trained set of M_1 and M_2, and we attack using the M_1 model to change the label to a speaker from the opposite gender and evaluate it on M_2. We flip between the two gender labels provided in the LibriSpeech dataset.

In this attack, we assume we cannot access the model M_2. For a sample $s \in testdata(M_2)$, we make a prediction using M_1. We then apply an iterative FGSM attack in M_1 to flip the identity so that the gender label flips. We call the attacked sample $\hat{s}$, following $(gender(M_1(s)) \neq gender(M_1(\hat{s})))$. We evaluate $\hat{s}$ on M_2 and call the attack successful if the prediction changes, in other words, $M_2(s) \neq M_2(\hat{s})$.

In the second experiment, we use the source model trained on 800 speakers and fine-tune the model on a new set of 127 speakers with one speaker C_s common to the substitute and source models. We perform targeted FGSM attack using the source model, such that the identity of every sample in the target model is changed to C_s.

V. Results and Discussion

Vanilla iterative attack vs. Top-k pixel attack: On training the CNN [5] model on the selected 927 speakers of LibriSpeech [12] corpus, we get an accuracy of 98.7% on the test set with an average confidence of 93% for prediction. Despite the network having such high accuracy and high confidence in the prediction, Table I shows that vanilla iterative FGSM can change samples from any 927 speakers to every other speaker in the dataset with minimal changes. The distortions in the audio caused by the attack are imperceptible in most cases, with a mean MOS of 0.08 in distinguishing the speech generated from original and attached spectrograms. We also show the results for the fifty samples which incurred most iterations in Table I. We observe higher distortion in these samples, with mean MOS jumping to 0.79. This correlation between the number of iterations and distortion can be observed from both qualitative and quantitative results Table I.

Table I further shows that allowing attack on only 2.5% pixels can still give an attack success rate of 89.2% in flipping every speaker to any other speaker in the dataset. It gives no significant added distortion to the audio as well. With a lower k, as low as 1.25% (about 300 pixels), we observe that 69% of the attacks are successful. As the MOS values indicate, both these attacks are almost imperceptible to humans.

To strengthen the claim of adversarial vulnerability of these models, we train the model with data augmentation (SpecAugment [24]) for randomly selected 200 speakers. We observe no significant improvement in robustness in simple iterative FGSM. We observe that the attack success rate remains the same post-augmentation, with the average number of iterations being 123.19 (without augmentation, the average number of iterations for the selected two hundred speakers is 113.11). The corresponding distortions are imperceptible.

Time period and frequency band attack: When the number of pixels modified is restricted to a time band as small as 2 frames (that is equivalent to 23ms), the average MOS score across different placements of the time band is 1.05. Table IV shows that the distortion is more perceptible when the time band appears in the middle of the audio clip compared to the beginning or end. In our study, the MOS when the mask is placed in the center is at least 50% more than the next best placement. It is interesting to note that the model prediction changes with a distortion limited to just 2ms output of an audio that spans three seconds. The distortion becomes less (and almost imperceptible) when the time window is increased to 30 frames (or 0.34s) with a mean MOS of 0.6.

Table III shows that the distortion caused by restricting

attacks to a specific frequency band is almost imperceptible irrespective of where we place the band except on the two bands on the extreme end of the spectrum. We hypothesize that since the lower frequencies(0-1 KHz) have higher activity with higher amplitudes, they are more perceptible with even minor distortions leading to significant audible differences. Our experiments show that with a sufficiently large band of 1 KHz, we can successfully attack the system in the range of 2-7 KHz without incurring much distortion in the audio.

Using a substitute model: On training the CNN [5] model such that target model (M2) has 121 speakers fine tuned with the backbone of pretrained model M1 on the selected 800 speakers of LibriSpeech [12] corpus, we get an accuracy of 100%. Despite the network having such high accuracy, Table II shows that iterative FGSM can change samples from any of the male speakers to every other female speaker in the dataset and vice versa with minimal change.

Transferability of attacks: We show the transferability of attacks using samples crafted from publicly available pre-trained models. We create a substitute model by training speaker detection on a portion of speakers. We fine-tune the model on a new set of 121 speakers with no speaker common to the substitute model label set. Here we observe an attack success rate of 84.2% when attack sample is crafted using substitute pretrained model and attack is performed on the fine-tuned model. The attack success rate is 91.6% when the source speaker is male and target speaker is female. Similarly, the attack success rate is 85.2% when source speaker is a female from the set of 800 speakers, and target speaker is a male from the set of 121 speakers.

We also fine-tune the model on a new set of 200 speakers with one speaker C_s common to the substitute model label set. We observe an attack success rate of 60% (with attack target C_s) when attack sample is crafted using substitute pretrained model and attack is performed on the fine-tuned model. This shows that with no access to the fine-tuned model, we can successfully attack a model with assumptions about the backbone.

Attack Cost vs. Success Rate In this section, we discuss the trade-off between Attack Success Rate (ASR) and the cost incurred for an attack measured in terms of the iterations required for the attack to succeed. In each run, we fix the maximum number of iterations required. We report the success rate over a range of iterations. Figure 3(a) shows the attack success and the iterations required for vanilla iterative FGSM attack. With just 186 iterations, we can achieve a 100% success rate with an average of 61 iterations across samples. For Top-k pixel attack, we can observe from Figure 3 (b) that with increase in k, the attack success rate increases. Which suggests it is easy to attack if we can modify more pixels. It can also be observed that attack success rates and iterations required are inversely correlated, suggesting if it is easy to attack a sample, it would require less number of iterations and attack success rate would be more. Conversely, if it is difficult to attack, the attack success rate would be less and requires large number of iterations.

We study the success-rate vs. iteration trade-off in frequency band and time period restricted attacks. Figure 3(c) shows the attack success rates vary across frequency bands. When limiting the number of iterations to 5000, the attack success rate largely decreases with frequency while the number of iterations required increases. Figure 3(d) shows the impact of the adversarial attack on time bands positioned at different positions (Start, Middle, and End) for a time band of 30 frames. The attack success rate remains above 75% across all three positions, while the number of iterations required is lower for the first position.

VI. CONCLUSIONS

We explored the adversarial robustness of the state-of-the-art speaker recognition system built from convolution operations. We observe that a vanilla FGSM attack can successfully flip speaker labels of every speaker to any other sample without perceivable changes to the audio. Further, the distortion in audio is proportional to the number of gradient updates in FGSM but is not correlated to the distance between the

embeddings learned by the speaker discriminator. We also evaluate the efficacy of adversarial attacks when the attack is restricted to a small set of pixels or a small band of time or frequency within the spectrogram, and empirical results show that it is possible to trick the classifier without major perturbations to the input. We would like to study further if these observations hold to the numerous downstream tasks which is very likely, and explore avenues for improving these high accuracy systems to be more robust to such attacks.

***Abstract*—This paper describes a multi-task learning method that detects the onset times of drums and the beat and downbeat times from a music signal. Since the drum part typically consists of repetitive patterns synchronized with the metrical structure in popular music, drum transcription and metrical analysis would benefit each other. The basic approach is to train a deep neural network (DNN) with a branching architecture that extracts latent features common to both tasks from a music signal and then feeds them to task-specific networks separately. The estimated frame-level posterior probabilities of drum onsets, beats, and downbeats, however, often have weak and inconsistent periodic structures. To solve this problem, we propose a regularized training method that encourages the three probability sequences to be highly auto- and cross-correlated. Specifically, our method aims to minimize the entropy of the auto-spectrum computed from each probability sequence and that of the cross-spectrum computed from each of the three sequence pairs, because a smaller entropy indicates a stronger element-wise periodicity or pairwise consistency. The experiment showed the mutual benefit of drum transcription and metrical analysis and the effectiveness of the periodicity- and consistency-based regularizations.**

I. Introduction

Automatic drum transcription (ADT) is one of the most fundamental subtasks of automatic music transcription (AMT) that aims to estimate the symbolic score of a music signal. Since the drum part affects the rhythmic characteristics of the song in popular music, drum transcription forms the basis of music information retrieval (MIR). Although the ultimate goal of ADT is audio-to-score transcription, we focus on audio-to-MIDI transcription that aims to estimate the onset times of drums in seconds as an intermediate goal.

In recent studies on audio-to-MIDI drum transcription, deep neural networks (DNNs) have successfully been used for estimating from a music spectrogram the posterior probabilities of the presence of drum onsets at the frame level [1]–[3]. Given a ground-truth binary sequence representing the presence or absence of drum onsets, one can train a DNN such that the posterior probability of the binary sequence is maximized, i.e., the cross-entropy loss is minimized. If only a limited amount of training data is available as is often the case with AMT [4], [5], however, the repetitive structures of the drum part observed at multiple metrical levels might not be captured well.

In this paper, we take the multi-task learning approach to joint drum transcription and metrical analysis (beat and downbeat detection). Both tasks are typically defined as binary classification problems that aim to estimate the presence or absence of drum onsets, beats, and downbeats at the frame level, and are expected to benefit each other by extracting common latent features with respect to periodicity from a music signal [2]. In this approach, one may train a DNN with a common feature extractor followed by task-specific binary classifiers. In such a basic branching architecture, however, the posterior probabilities of drum onsets, beats, and downbeats are estimated in a conditionally independent manner and are thus not guaranteed to be consistent in terms of periodicity.

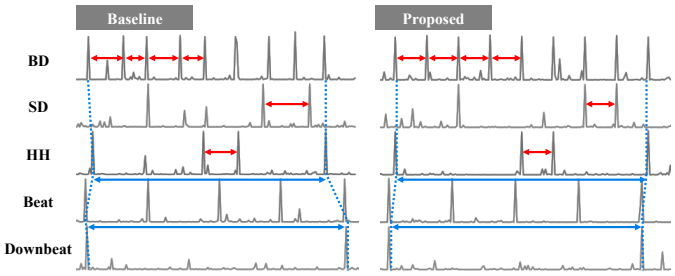

Fig. 1. The frame-level sequences of drum onset, beat, and downbeat probabilities estimated by the multi-task learning method without/with the periodicity-aware regularization. The red and blue arrows indicate the element-wise periodicity and pairwise consistency, respectively.

To mitigate this problem, we propose a regularized training method that encourages the sequences of drum onset, beat, and downbeat probabilities to have periodic patterns synchronously (Fig. 1). We focus on the fact that the tempo tends to be kept constant throughout the entire song in popular music. This requests that each sequence should have clear periodicity solely and that a sequence should share the same periodicity with another sequence. We thus propose element-wise and pairwise regularization terms described in detail below.

First, we focus on the auto-correlation function of each sequence. If the sequence of drum onset probabilities is repetitive at the measure level, its auto-correlation function exhibits sharp peaks spaced at the downbeat interval. The auto-spectrum obtained by applying the discrete Fourier transform (DFT) to the auto-correlation function exhibits a few peaks at the downbeat frequency. The *entropy of the auto-spectrum* can thus be used as a regularization term to be minimized. The same applies to the sequences of beat and downbeat probabilities exhibiting the periodicity at the beat and downbeat levels.

Second, we focus on the cross-correlation function for each of the three sequence pairs. In general, every time the sequence

979-8-3503-0067-3/23/$31.00 ©2023 IEEE

of drum onset probabilities is time-shifted by a downbeat interval, it matches well the sequence of downbeat probabilities in terms of peak positions. The cross-correlation function exhibits sharp peaks spaced at the downbeat interval. The *entropy of the cross-spectrum* can thus be another regularization term. The same applies to the other two pairs.

We experimentally show that the multi-task learning approach is especially effective for improving the performance of metrical analysis and the regularized training method has a potential of improving the performances of drum transcription and metrical analysis.

II. Related Work

Deep learning has been the central choice in modern ADT [2], [3], [5]–[10]. In general, a deep neural network (DNN) is trained in a supervised manner using paired data consisting of music signals and drum onset annotations. Due to the impulsive nature of drums sounds, CNNs have widely been used as basic building blocks for extracting local features. In particular, a CNN variant called the temporal convolutional network (TCN) [11], [12] has gained much attention because it can take into account both short- and long-term dependencies [13]. To consider long-term contextual information, a CNN is often followed by a recurrent neural network (RNN), resulting in a convolutional RNN (CRNN) [2].

To improve the performance with a limited amount of paired data, one may use data synthesis [14], data augmentation [5], or unsupervised learning [15]. However, these methods are still insufficient for dealing with considerable variations in real-world drum sounds. Alternatively, regularized training techniques based on prior knowledge of drum patterns have been explored [10] as well as phase consideration [16] and architectural innovations [7]. In this study, we focus on the periodicity of drum onsets for regularization.

For metrical analysis, DNN-HMM combinations have often been used [13], [17]–[20]. In this approach, a DNN is used for estimating sequences of beat and downbeat probabilities, and an HMM is then used for detecting beat and downbeat times from these sequences. Instead of the standard HMM, a hidden semi-Markov model (HSMM) that explicitly represents the duration of each state was proven to be effective for taking into account the tempo and meter consistency of beat and downbeat times. In this study, we use a similar HSMM-based decoder to obtain consistent results.

III. Proposed Method

This section describes the multi-task learning of drum transcription and metrical analysis with a periodicity-aware regularized training method.

A. Problem Specification

We tackle drum transcription and beat and downbeat detection from a music signal. We use the power spectrograms of the left and right channels of the audio signal $\mathbf{X} \in \mathbb{R}^{2\times F\times T}$ as input. Let $\mathbf{Y}^{\mathrm{D}} \in \{0,1\}^{K\times T}$, $\mathbf{Y}^{\mathrm{B}} \in \{0,1\}^{T}$, and $\mathbf{Y}^{\mathrm{W}} \in \{0,1\}^{T}$ denote the presence or absence of drum onsets, that of beats, and that of downbeats at the frame level, respectively, where F is the number of frequency bins, T is the number of frames, and K is the number of drum instruments. We focus on the three major drum classes ($K = 3$): bass drum (BD), snare drum (SD), and hi-hats (HH). Let $\mathbf{Y} \triangleq \{\mathbf{Y}^{\mathrm{D}}, \mathbf{Y}^{\mathrm{B}}, \mathbf{Y}^{\mathrm{W}}\}$. In the training phase, both $\mathbf{X}$ and $\mathbf{Y}$ are given as paired data. In the test phase, $\mathbf{Y}$ is estimated from $\mathbf{X}$.

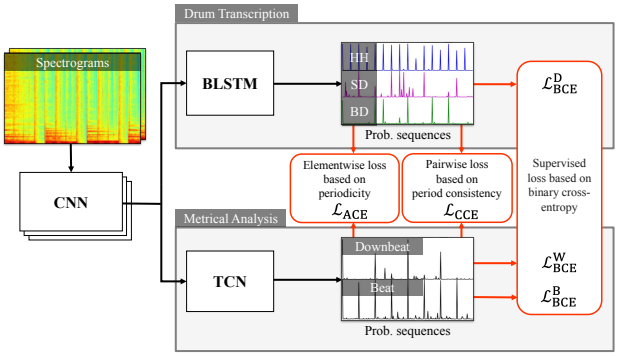

Fig. 2. The proposed joint drum transcription and metrical analysis based on periodicity-aware regularized multi-task learning.

B. Multi-Task Learning

We explain the loss function to be minimized for joint drum transcription and metrical analysis. Inspired by [17], [20], we use a CRNN with a branching architecture for jointly estimating a sequence of drum onset probabilities $\boldsymbol{\phi}^{\mathrm{D}} \in [0,1]^{K\times T}$, that of beat probabilities $\boldsymbol{\phi}^{\mathrm{B}} \in [0,1]^{T}$, and that of downbeat probabilities $\boldsymbol{\phi}^{\mathrm{D}} \in [0,1]^{T}$ from the input $\mathbf{X}$ (Fig. 2).

1) Drum Transcription Loss: The drum transcription loss is given by the binary cross-entropy (BCE) of $\boldsymbol{\phi}^{\mathrm{D}}$ for the ground-truth data $\mathbf{Y}^{\mathrm{D}}$:

$$\mathcal{L}^{\mathrm{D}}_{\mathrm{BCE}} = -\frac{1}{K}\sum_{k,t=1}^{K,T}\left(Y^{\mathrm{D}}_{kt}\log\phi^{\mathrm{D}}_{kt} + (1-Y^{\mathrm{D}}_{kt})\log(1-\phi^{\mathrm{D}}_{kt})\right). \quad (1)$$

2) Metrical Analysis Losses: The metrical analysis losses are given by the BCEs of $\boldsymbol{\phi}^{\mathrm{B}}$ and $\boldsymbol{\phi}^{\mathrm{W}}$ for the ground-truth data $\mathbf{Y}^{\mathrm{B}}$ and $\mathbf{Y}^{\mathrm{W}}$:

$$\mathcal{L}^{\mathrm{B}}_{\mathrm{BCE}} = -\sum_{t=1}^{T}\left(Y^{\mathrm{B}}_{t}\log\phi^{\mathrm{B}}_{t} + (1-Y^{\mathrm{B}}_{t})\log(1-\phi^{\mathrm{B}}_{t})\right), \quad (2)$$

$$\mathcal{L}^{\mathrm{W}}_{\mathrm{BCE}} = -\sum_{t=1}^{T}\left(Y^{\mathrm{W}}_{t}\log\phi^{\mathrm{W}}_{t} + (1-Y^{\mathrm{W}}_{t})\log(1-\phi^{\mathrm{W}}_{t})\right). \quad (3)$$

3) Total Loss: For joint training, we aim to minimize the weighted sum of the individual losses:

$$\mathcal{L}_{\mathrm{BCE}} = \lambda^{\mathrm{D}}_{\mathrm{BCE}}\mathcal{L}^{\mathrm{D}}_{\mathrm{BCE}} + \lambda^{\mathrm{B}}_{\mathrm{BCE}}\mathcal{L}^{\mathrm{B}}_{\mathrm{BCE}} + \lambda^{\mathrm{W}}_{\mathrm{BCE}}\mathcal{L}^{\mathrm{W}}_{\mathrm{BCE}}, \quad (4)$$

where $\lambda^{\mathrm{D}}_{\mathrm{BCE}}$, $\lambda^{\mathrm{B}}_{\mathrm{BCE}}$, and $\lambda^{\mathrm{W}}_{\mathrm{BCE}}$ are adjustable weights.

C. Periodicity-Aware Regularization

We explain regularization terms that encourage element-wise periodicity and pairwise consistency. We first explain the core ideas underlying the regularization terms (Figs. 3(a) and 3(b)) and describe the regularization terms.

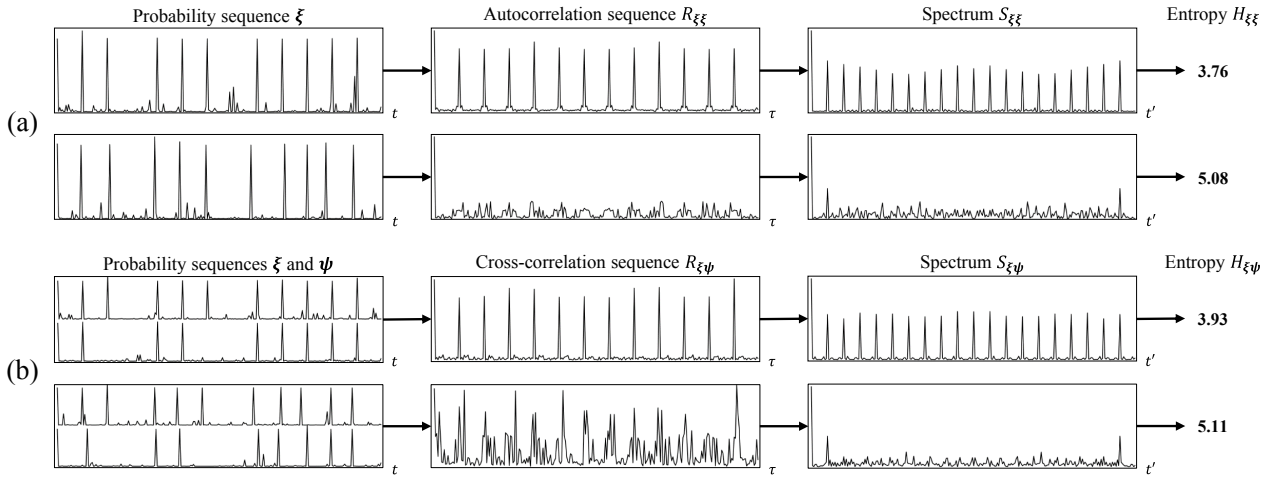

Fig. 3. (a) Examples of probability sequences and the corresponding auto-correlation functions and auto-spectra with entropies. A more periodic probability sequence results in the auto-spectrum with a smaller entropy. (b) Examples of probability sequence pairs and the corresponding cross-correlation functions and cross-spectra with entropies. A more consistent probability sequence pair results in the cross-spectrum with a smaller entropy.

1) Auto-Correlation Analysis: The auto-correlation function for a probability sequence $\boldsymbol{\xi} \in [0,1]^T$ is given by

$$R_{\boldsymbol{\xi}\boldsymbol{\xi}}(\tau) = \frac{1}{T}\sum_{t=1}^{T} \xi_t \xi_{(t+\tau-1)\%T+1}, \tag{5}$$

where $\%$ represents the modulo operation. Using the Wiener-Khinchin theorem, the spectrum of $R_{\boldsymbol{\xi}\boldsymbol{\xi}}$ is given by

$$S_{\boldsymbol{\xi}\boldsymbol{\xi}} = F R_{\boldsymbol{\xi}\boldsymbol{\xi}} = |F\boldsymbol{\xi}|^{\cdot 2}, \tag{6}$$

where $F \in \mathbb{C}^{T\times T}$ represents the discrete Fourier transform (DFT) matrix and $|\mathbf{a}|^{\cdot 2}$ represents the element-wise operation that takes the absolute square values of the elements of a vector $\mathbf{a}$. The entropy of the spectrum $S_{\boldsymbol{\xi}\boldsymbol{\xi}}$ is given by

$$H_{\boldsymbol{\xi}\boldsymbol{\xi}} = -\sum_{t=1}^{T} \bar{S}_{\boldsymbol{\xi}\boldsymbol{\xi}}(t) \log \bar{S}_{\boldsymbol{\xi}\boldsymbol{\xi}}(t), \tag{7}$$

$$\bar{S}_{\boldsymbol{\xi}\boldsymbol{\xi}} = \mathrm{Normalize}(S_{\boldsymbol{\xi}\boldsymbol{\xi}}), \tag{8}$$

where $\mathrm{Normalize}(\mathbf{a})$ represents the normalization operation that makes the sum of the elements of a vector $\mathbf{a}$ equal to 1. If the probability sequence $\boldsymbol{\xi}$ has clear periodicity, i.e., it has regular periodic patterns and the peak intervals are integer multiples of some basic time unit (e.g., tatum, beat, or downbeat), the auto-correlation function and the auto-spectrum have equally-spaced sharp peaks. The negative entropy $-H_{\boldsymbol{\xi}\boldsymbol{\xi}}$ can be used as an indicator of periodicity.

2) Cross-Correlation Analysis: The cross-correlation function for probability sequences $\boldsymbol{\xi}, \boldsymbol{\psi} \in [0,1]^T$ is given by

$$R_{\boldsymbol{\xi}\boldsymbol{\psi}}(\tau) = \frac{1}{T}\sum_{t=1}^{T} \xi_t \psi_{(t+\tau-1)\%T+1}. \tag{9}$$

Using the Wiener-Khinchin theorem, the magnitude spectrum of $R_{\boldsymbol{\xi}\boldsymbol{\psi}}$ is given by

$$S_{\boldsymbol{\xi}\boldsymbol{\psi}} = |F R_{\boldsymbol{\xi}\boldsymbol{\psi}}|^{\cdot} = |(F\boldsymbol{\xi})^* \odot (F\boldsymbol{\psi})|^{\cdot}, \tag{10}$$

where $\mathbf{a}^*$ represents the element-wise conjugate operation for a vector $\mathbf{a}$, $\odot$ represents the element-wise multiplication, and $|\mathbf{a}|^{\cdot}$ represents the element-wise operation that takes the absolute values of the elements of a vector $\mathbf{a}$. The entropy of the spectrum $S_{\boldsymbol{\xi}\boldsymbol{\psi}}$ is given by

$$H_{\boldsymbol{\xi}\boldsymbol{\xi}} = -\sum_{t=1}^{T} \bar{S}_{\boldsymbol{\xi}\boldsymbol{\psi}}(t) \log \bar{S}_{\boldsymbol{\xi}\boldsymbol{\psi}}(t), \tag{11}$$

$$\bar{S}_{\boldsymbol{\xi}\boldsymbol{\psi}} = \mathrm{Normalize}(S_{\boldsymbol{\xi}\boldsymbol{\psi}}). \tag{12}$$

If the probability sequences $\boldsymbol{\xi}$ and $\boldsymbol{\psi}$ are consistent in terms of periodicity, i.e., they have synchronous periodic patterns, the cross-correlation function and the cross-spectrum have equally-spaced sharp peaks. The negative entropy $-H_{\boldsymbol{\xi}\boldsymbol{\psi}}$ can be used as an indicator of consistency.

3) Element-Wise Regularization: We propose element-wise regularization terms, denoted by $\mathcal{L}^{\mathrm{D}}_{\mathrm{ACE}}$, $\mathcal{L}^{\mathrm{B}}_{\mathrm{ACE}}$, and $\mathcal{L}^{\mathrm{W}}_{\mathrm{ACE}}$, based on the auto-correlation entropy (ACE) of the drum onset probability sequence $\boldsymbol{\phi}^{\mathrm{D}}$, that of the beat probability sequence $\boldsymbol{\phi}^{\mathrm{B}}$, and that of the downbeat probability sequence $\boldsymbol{\phi}^{\mathrm{W}}$:

$$\mathcal{L}^{\mathrm{D}}_{\mathrm{ACE}} = -\frac{1}{K}\sum_{k,t=1}^{K,T} \bar{\phi}^{\mathrm{D}}_{kt} \log \bar{\phi}^{\mathrm{D}}_{kt}, \tag{13}$$

$$\bar{\boldsymbol{\phi}}^{\mathrm{D}}_{k} = \mathrm{Normalize}(|F\boldsymbol{\phi}^{\mathrm{D}}_{k}|^{\cdot 2}), \tag{14}$$

$$\mathcal{L}^{\mathrm{B}}_{\mathrm{ACE}} = -\sum_{t=1}^{T} \bar{\phi}^{\mathrm{B}}_{t} \log \bar{\phi}^{\mathrm{B}}_{t}, \tag{15}$$

$$\bar{\boldsymbol{\phi}}^{\mathrm{B}} = \mathrm{Normalize}(|F\boldsymbol{\phi}^{\mathrm{B}}|^{\cdot 2}), \tag{16}$$

$$\mathcal{L}^{\mathrm{W}}_{\mathrm{ACE}} = -\sum_{t=1}^{T} \bar{\phi}^{\mathrm{W}}_{t} \log \bar{\phi}^{\mathrm{W}}_{t}, \tag{17}$$

$$\bar{\boldsymbol{\phi}}^{\mathrm{W}} = \mathrm{Normalize}(|F\boldsymbol{\phi}^{\mathrm{W}}|^{\cdot 2}), \tag{18}$$

where $\boldsymbol{\phi}^{\mathrm{D}}_{k} \in [0,1]^T$ denotes the drum onset probability sequence for drum class k.

We aim to minimize the weighted sum of the individual regularization terms:

$$\mathcal{L}_{\text{ACE}} = \lambda^{\text{D}}_{\text{ACE}}\mathcal{L}^{\text{D}}_{\text{ACE}} + \lambda^{\text{B}}_{\text{ACE}}\mathcal{L}^{\text{B}}_{\text{ACE}} + \lambda^{\text{W}}_{\text{ACE}}\mathcal{L}^{\text{W}}_{\text{ACE}}, \tag{19}$$

where $\lambda^{\text{D}}_{\text{ACE}}$, $\lambda^{\text{B}}_{\text{ACE}}$, and $\lambda^{\text{W}}_{\text{ACE}}$ are adjustable weights.

4) Pairwise Regularization: We propose pairwise regularization terms, denoted by $\mathcal{L}^{\text{DB}}_{\text{CCE}}$, $\mathcal{L}^{\text{DW}}_{\text{CCE}}$, and $\mathcal{L}^{\text{BW}}_{\text{CCE}}$, based on the cross-correlation entropy (CCE) for each of the possible pairs between the drum onset probability sequence $\boldsymbol{\phi}^{\text{D}}$, the beat probability sequence $\boldsymbol{\phi}^{\text{B}}$, and the downbeat probability sequence $\boldsymbol{\phi}^{\text{W}}$:

$$\mathcal{L}^{\text{DB}}_{\text{CCE}} = -\frac{1}{K}\sum_{k,t=1}^{K,T} \bar{\phi}^{\text{DB}}_{kt} \log \bar{\phi}^{\text{DB}}_{kt}, \tag{20}$$

$$\bar{\boldsymbol{\phi}}^{\text{DB}}_{k} = \text{Normalize}(|F\boldsymbol{\phi}^{\text{D}}_{k}|^{\cdot} \odot |F\boldsymbol{\phi}^{\text{B}}|^{\cdot}), \tag{21}$$

$$\mathcal{L}^{\text{DW}}_{\text{CCE}} = -\frac{1}{K}\sum_{k,t=1}^{K,T} \bar{\phi}^{\text{DW}}_{kt} \log \bar{\phi}^{\text{DW}}_{kt}, \tag{22}$$

$$\bar{\boldsymbol{\phi}}^{\text{DW}}_{k} = \text{Normalize}(|F\boldsymbol{\phi}^{\text{D}}_{k}|^{\cdot} \odot |F\boldsymbol{\phi}^{\text{W}}|^{\cdot}), \tag{23}$$

$$\mathcal{L}^{\text{BW}}_{\text{CCE}} = -\sum_{t=1}^{T} \bar{\phi}^{\text{BW}}_{t} \log \bar{\phi}^{\text{BW}}_{t}, \tag{24}$$

$$\bar{\boldsymbol{\phi}}^{\text{BW}} = \text{Normalize}(|F\boldsymbol{\phi}^{\text{B}}|^{\cdot} \odot |F\boldsymbol{\phi}^{\text{W}}|^{\cdot}). \tag{25}$$

We aim to minimize the weighted sum of the individual regularization terms:

$$\mathcal{L}_{\text{CCE}} = \lambda^{\text{DB}}_{\text{CCE}}\mathcal{L}^{\text{DB}}_{\text{CCE}} + \lambda^{\text{DW}}_{\text{CCE}}\mathcal{L}^{\text{DW}}_{\text{CCE}} + \lambda^{\text{BW}}_{\text{CCE}}\mathcal{L}^{\text{BW}}_{\text{CCE}}, \tag{26}$$

where $\lambda^{\text{DB}}_{\text{CCE}}$, $\lambda^{\text{DW}}_{\text{CCE}}$, and $\lambda^{\text{BW}}_{\text{CCE}}$ are adjustable weights.

5) Total Loss: For regularized joint training, we aim to minimize the sum of the basic supervised loss $\mathcal{L}_{\text{BCE}}$ in (4), the element-wise regularization term $\mathcal{L}_{\text{ACE}}$ in (19), and the pairwise regularization term $\mathcal{L}_{\text{CCE}}$ in (26):

$$\mathcal{L} = \mathcal{L}_{\text{BCE}} + \mathcal{L}_{\text{ACE}} + \mathcal{L}_{\text{CCE}}. \tag{27}$$

The weights can be adjusted for controlling the relative importance of different tasks.

D. Decoding

In the test phase, given $\mathbf{X}$, we jointly estimate the drum onset probability sequence $\boldsymbol{\phi}^{\text{D}}$, the beat probability sequence $\boldsymbol{\phi}^{\text{B}}$, and the downbeat probability sequence $\boldsymbol{\phi}^{\text{W}}$ using the trained CRNN. For improved performance, we use different decoding techniques for detecting the drum onsets $\mathbf{Y}^{\text{D}}$ and the beat and downbeat times $\mathbf{Y}^{\text{B}}$ and $\mathbf{Y}^{\text{W}}$.

1) Drum Transcription: The final output $\mathbf{Y}^{\text{D}}$ is obtained by performing peak-picking and thresholding for $\boldsymbol{\phi}^{\text{D}}$ as follows:

$$Y^{\text{D}}_{kt} = \begin{cases} 1 & (\phi^{\text{D}}_{kt} \geq \delta_k) \\ 0 & (\text{otherwise}) \end{cases}, \tag{28}$$

where δ_k is a threshold configured for each drum instrument.

2) Metrical Analysis: Since the naive thresholding has a limitation in performance, the final outputs $\mathbf{Y}^{\text{B}}$ and $\mathbf{Y}^{\text{W}}$ are detected from from $\boldsymbol{\phi}^{\text{B}}$ and $\boldsymbol{\phi}^{\text{W}}$ with a metrical analysis method based on a dynamic Bayesian network (DBN) [21].

We explain the decoding method for the beat probability sequence $\boldsymbol{\phi}^{\text{B}}$. The DBN is a hidden Markov model (HMM) with hidden states $\mathbf{z}_t = [c_t, \dot{c}_t]$ at frame t. Here, $c_t \in \{1, 2, \ldots, \dot{c}\}$ is a discrete random variable representing the position within a beat at frame t, and $\dot{c}_t \in \{\dot{c}_{\text{min}}, \dot{c}_{\text{min}}+1, \ldots, \dot{c}_{\text{max}}\}$ is the total number of discretized positions within one beat, which is a random variable representing the tempo at frame t, where $\dot{c}_{\text{min}}$ and $\dot{c}_{\text{max}}$ denote the minimum and maximum values of the tempo, respectively. Let Δ be the frame length of the audio signal and BPM_{t} represent the tempo in beats per minute at frame t. Then, $\dot{c}_t$ can be expressed as follows:

$$\dot{c}_t = \text{round}\left(\frac{4 \times 60}{\text{BPM}_{\text{t}} * \Delta}\right). \tag{29}$$

If we denote the observation sequence as $\{\mathbf{o}_t\}_{t=1}^{T}$, the probability model can be defined as follows:

$$p(\mathbf{z}_{1:T}, \mathbf{o}_{1:T}) = p(\mathbf{z}_{1:T})p(\mathbf{o}_{1:T}|\mathbf{z}_{1:T}). \tag{30}$$

Our goal is to estimate the hidden state sequence $\mathbf{z}^{*}_{1:T}$ with the maximum posterior probability as follows:

$$\mathbf{z}^{*}_{1:T} = \underset{z_{1:T}}{\text{argmax}}\, p(\mathbf{z}_{1:T}|\mathbf{o}_{1:T}), \tag{31}$$

$$p(\mathbf{o}_{1:T}|\mathbf{z}_{1:T}) \propto p(\mathbf{z}_1)\prod_{t=2}^{T} p(\mathbf{z}_t|\mathbf{z}_{t-1})p(\mathbf{o}_t|\mathbf{z}_t), \tag{32}$$

where $p(\mathbf{o}_t|\mathbf{z}_t)$ represents the observation model, and $p(\mathbf{z}_t|\mathbf{z}_{t-1})$ represents the transition model. Equation (31) can be solved efficiently using the Viterbi algorithm [22]. The term $p(\mathbf{z}_{1:T})$ in (30) represents the generative process of the hidden states $\mathbf{z}_{1:T}$, which is given by

$$p(\mathbf{z}_{1:T}) = p(\mathbf{z}_1)\prod_{t=2}^{T} p(\mathbf{z}_t|\mathbf{z}_{t-1}), \tag{33}$$

where $p(\mathbf{z}_1)$ represents the initial probability and $p(\mathbf{z}_t|\mathbf{z}_{t-1})$ represents the transition probability given by

$$p(\mathbf{z}_t|\mathbf{z}_{t-1}) = p(c_t|c_{t-1}, \dot{c}_{t-1})p(\dot{c}_t|\dot{c}_{t-1}), \tag{34}$$

$$p(c_t|c_{t-1}, \dot{c}_{t-1}) = \mathbb{1}_z. \tag{35}$$

where $\mathbb{1}_z$ is a function that takes 1 if $c_t = (c_{t-1}+1) \bmod \dot{c}_{t-1}$ and 0 otherwise. If $c_{t-1} = \dot{c}_{t-1}$, we have

$$p(\dot{c}_t|\dot{c}_{t-1}) = \exp\left(-\lambda\left|\frac{\dot{c}_t}{\dot{c}_{t-1}} - 1\right|\right), \tag{36}$$

where λ is a hyperparameter. Otherwise, we have

$$p(\dot{c}_t|\dot{c}_{t-1}) = \begin{cases} 1 & (c_t = c_{t-1} + 1) \\ 0 & \text{otherwise} \end{cases}. \tag{37}$$

Finally, for the hidden state sequence $\mathbf{x}^{*}_{1:T}$ with the maximum posterior probability, we detect all t's where $c_t = 1$. This sequence is the estimated beat time sequence.

IV. EVALUATION

This section reports a comparative experiment conducted for evaluating the proposed regularized multi-task learning method through ablation study.

A. Experimental Conditions

The RWC Music Database: Popular Music [23] was used for evaluation. It consists of 100 Japanese popular songs (J-POP) with human-performed and synthesized drum tracks. We used 64 songs with accurate drum onset annotations and 10 songs without drum annotations. The stereo signals at a sampling rate of 44.1 kHz were processed using short-time Fourier transform (STFT) with a window size of 1024 points and a hop size of 441 points. The left and right channels were concatenated to form the input matrix $\mathbf{X}$.

Our CRNN consists of common convolutional layers for feature extraction followed by a bidirectional long short-term memory (BLSTM) network for drum transcription and a TCN for metrical analysis (Fig. 2). The convolutional layers, with a kernel size of 3×3, a padding size of 1×1, and a stride of 1, yielded a (512×4)-dimensional feature map, on which a dropout of 30% was applied before feeding it into a linear layer. The BLSTM network had three layers, each of which had hidden states of 200 dimensions. The TCN had eleven layers with a receptive field of about 80 [s]. The weights were set as follows: $\lambda^{\mathrm{D}}_{\mathrm{BCE}}=1$, $\lambda^{\mathrm{B}}_{\mathrm{BCE}}=\lambda^{\mathrm{W}}_{\mathrm{BCE}}=0.1$, $\lambda^{\mathrm{D}}_{\mathrm{ACE}}=1$, $\lambda^{\mathrm{B}}_{\mathrm{ACE}}=\lambda^{\mathrm{W}}_{\mathrm{ACE}}=0$, and $\lambda^{\mathrm{DB}}_{\mathrm{CCE}}=\lambda^{\mathrm{DW}}_{\mathrm{CCE}}=\lambda^{\mathrm{BW}}_{\mathrm{CCE}}=1$. We used AdamW [24] with a learning rate of $\gamma = 0.001$, weight decays parameters of $\lambda = 10^{-4}$, $\beta_1 = 0.9$, $\beta_2 = 0.98$, and $\varepsilon = 10^{-9}$ for optimization.

To evaluate the effectiveness of the individual components of the proposed method, we conducted an ablation study. We tackled drum transcription and metrical analysis jointly or separately with or without the element-wise and pairwise regularization terms. Five-fold cross-validation was conducted, where the performance was evaluated on the 64 songs with drum annotations. We also compared the proposed method with a state-of-the-art method [20].

The performances of drum transcription and metrical analysis were evaluated in terms of the F-measure with error tolerances of 30 [ms] and 70 [ms], respectively. The beat interval stability was also evaluated in terms of the CMLt and AMLt metrics [25] that consider double/half tempo ambiguity in beat interpretation. Note that the drum onset annotations might be inconsistent due to the characteristics of annotators. In the training phase, the ground-truth onset times were perturbed by being convolved with a Gaussian distribution with a mean of 0 [ms] and a standard deviation of 12 [ms]. For data augmentation, the time stretch operation was applied to each song with a scaling factor drawn from a Gaussian distribution with a mean of 1 and a standard deviation of 0.1.

TABLE II
THE PERFORMANCES OF METRICAL ANALYSIS FOR 100 SONGS OF RWC POPULAR MUSIC DATABASE. BOLD FONTS INDICATE THE BEST VALUES.

Ours	**92.8**	**85.9**	**94.3**	**86.3**	**81.3**	**89.4**

B. Experimental Results

As shown in Table I, the multi-task learning approach improved the beat and downbeat detection performances by approximately 4 and 2 pts, respectively, compared with the single-task learning approach. Both the elementwise and pairwise regularizations improved the performance of drum transcription by approximately 1–3 pts. For metrical analysis, in contrast, no significant improvement was observed, mainly because the DBN-based decoding had a dominant impact on the results. If the naive thresholding was used instead, some performance gain was obtained (not reported in the table). As shown in Table II, the configuration that achieved the best performance of beat detection for all the 100 songs of the RWC Popular Music Database (the ninth row in Table I) outperformed the state-of-the-art method [20] by approximately 3 pts higher.

Fig. 4 shows the positive and negative effects of the multi-task learning. In the left example, since the drum onsets were located on the beat and tatum grids, the snare drum onsets on unnatural positions were suppressed successfully. In contrast, in the right example, although the drum onsets with swing rhythm were deviated from the beat and tatum grids, they were encouraged to be synchronized with the grids.

Fig. 5 shows the positive effect of the regularized training. The histogram of the inter-onset intervals (IOIs) of the hi-hat onsets had a single sharp peak, meaning that the estimated onsets were placed at a constant interval. Such periodicity-aware regularization, however, might fail to estimate non-regular drum patterns (e.g., fill-ins) and degrade the performance.

These results suggest the importance of the weight configuration according to the target data. One promising solution worth investigation would be to use the self-attention mechanism for automatically adjusting the weights according to the regularity of drum patterns.

V. CONCLUSION

In this paper, we presented a multi-task learning approach to joint drum transcription and metrical analysis based on the periodicity-aware element-wise and pairwise regularization terms. Specifically, our method aims to minimize the entropy

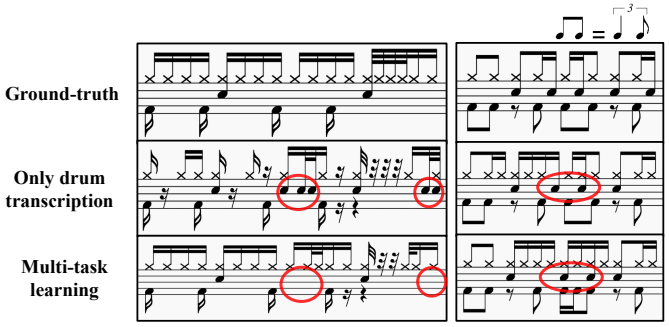

Fig. 4. Examples of drum transcription results obtained with the multi-task and single-task learning approaches. The performance was improved in the left example and was degraded in the right example.

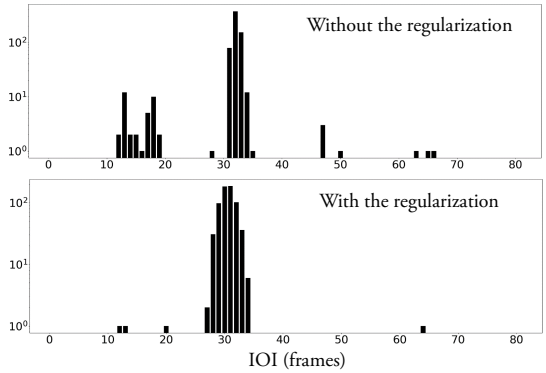

Fig. 5. Histograms of inter-onset intervals (IOIs) in frame units computed from hi-hat onsets detected without/with the regularization (RWC-MDB-P-2001 No. 11).

of the auto-spectrum computed from each probability sequence and that of the cross-spectrum computed from each of the three sequence pairs, because a smaller entropy indicates a stronger element-wise periodicity or pairwise consistency. We experimentally showed the effectiveness of using the multi-task learning and the regularized training for drum transcription. The performance of metrical analysis, however, was not maximized by the concurrent use of these methods. Further investigation is thus needed to determine the weights of the loss functions appropriately for each task, compare with other deep learning methods, and explore a peak detection method that maximizes the performance of the proposed method. In addition, we plan to investigate a new regularization term based on the fractal structure inherent in music.

***Abstract*—This paper describes end-to-end automatic drum transcription for directly estimating a drum score from an audio signal of popular music using non-aligned paired data. We aim to convert a sequence of frame-level acoustic features into a sequence of tatum-level score fragments (three-dimensional multi-hot vectors) representing the presence or absence of the onsets of the bass and snare drums and the hi-hats. The main challenge of this task lies in estimating the correct number of inactive tatums having no onset between active tatums. One may use the connectionist temporal classification (CTC) for end-to-end training of a deep neural network (DNN) that infers a frame-level state sequence (alignment path) including the special "blank" states representing the tatum boundaries. At run-time, a drum score is obtained by annexing repeated states and removing all blank states from the most likely frame-level state sequence. This approach, however, tends to yield a shortened drum score in which repeated inactive tatums are annexed mistakenly because the blank state (tatum boundary) cannot be distinguished acoustically from the inactive state (onset absence) at the frame level. In this paper, we propose a sophisticated version of the CTC with constant tempo constraint, CTC2 in short, that encourages each tatum to be aligned with almost the same number of frames. Although the loss function can be computed efficiently as in the basic CTC, the backpropagation over the huge computation graph made through the forward algorithm is computationally prohibitive. To solve this problem, we propose to perform the backpropagation with only an alignment path stochastically drawn with Gibbs sampling. The experiment showed that the proposed method worked well as expected.**

I. Introduction

Automatic drum transcription (ADT) is a fundamental task that aims to estimate a drum score (MusicXML format) from a music signal. Although ADT plays a key role in computational music understanding, it has been tackled only partially; most studies aim to estimate a piano roll (MIDI format) by detecting the onset times of drums in seconds [1], [2]. To estimate a drum score, for example, one may estimate the beat and downbeat times in advance [3], [4] and then perform quantized onset detection [5]. Instead, one may take a more sophisticated approach in the same way as the state-of-the-art automatic piano transcription [6] based on the combination of audio-to-MIDI transcription [7] and MIDI-to-score transcription (rhythm transcription) [8]. Such a cascading approach, however, suffers from the error propagation problem.

Inspired by the great success of end-to-end automatic speech recognition (ASR), end-to-end automatic music transcription (AMT) has recently been investigated [9]–[13]. This approach can circumvent the error propagation problem and make effective use of non-aligned pairs of music signals and the corresponding scores as training data. Considering the monotonic nature of the audio-to-score mapping, we focus on the connectionist temporal classification (CTC) [14] (cf. [9]) because it is expected to work stably with a limited amount of training data, compared with the encoder-decoder model (cf. [10]) and that with the attention mechanism [15] (cf. [11]–[13]).

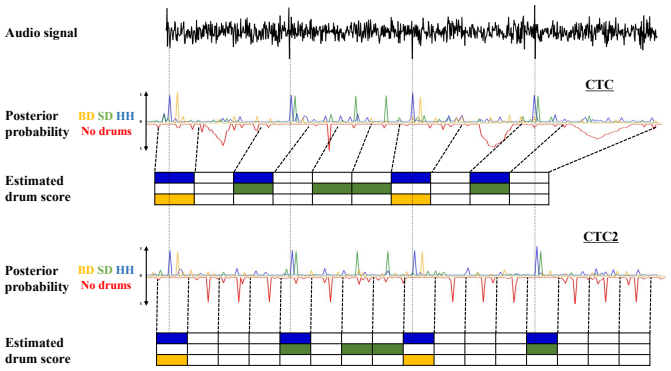

Fig. 1. The comparison of the basic CTC and the proposed CTC with constant tempo constraint (CTC2). The repeated inactive tatums having no drum onsets can be estimated correctly by encouraging the frames to be segmented into the tatums with almost the same length.

End-to-end AMT methods can also be characterized by their score representations: how to define symbols constituting the output sequence. The representation affects the difficulty unique to AMT in estimating the temporal information about note values (quantized durations) and metrical structures. The basic way is to convert a sequence of frame-level acoustic features into a sequence of *notation-level score components* (e.g., notes and bars) [12]. The note values (temporal attribute), however, are considerably harder to estimate than the note pitches (instantaneous attribute) with the basic input-output alignment mechanism. Another way is to estimate a sequence of *tatum-level score fragments* [11], where the tatum is a basic time unit on the score at the sub-beat level (typically at the sixteenth-note level). Instead of directly estimating the note values, this approach aims to estimate the presence or absence of the note onsets (instantaneous attribute) at the tatum level.

979-8-3503-0067-3/23/$31.00 ©2023 IEEE

In this paper we tackle CTC-based ADT that aims to estimate a sequence of tatum-level score fragments (Fig. 1). Each fragment (tatum) is represented as a three-dimensional multi-hot vector indicating the presence or absence of the onsets of the bass and snare drums and the hi-hats (eight states in total). The main challenge unique to this task is to estimate the correct number of inactive tatums (a state corresponding to the all-zero vector) between active tatums (the other seven states). If the basic CTC is used for end-to-end training, the state of each tatum of the ground-truth sequence is associated with frames of the input sequence whose acoustic features are particularly relevant to the state through forced alignment. Such frames are typically only at the beginning of the tatum; the special blank state (denoted by "_") is associated with the other acoustically irrelevant frames. At run-time, however, successive inactive tatums are annexed mistakenly because the blank state (tatum boundary) and the inactive state (onset absence) are hard to distinguish acoustically at the frame level.

To solve this problem, we propose a sophisticated version of the CTC with constant tempo constraint, CTC2 in short, based on the reasonable assumption that the tempo is usually kept constant throughout the song in popular music (Fig. 1). In the basic CTC, the frame-to-tatum alignment is obtained through unconstrained time stretch because only the order of output symbols (states) matters and their durations are ignored, as in the inference of the latent state sequence of the hidden Markov model (HMM). Inspired by the hidden semi-Markov model (HSMM) with explicit duration modeling [16], we instead encourage the tatum boundaries (transitions between the main eight states and the blank state) to occur regularly with a constant interval, where adjacent tatums favor to have the same duration [3], [17]. This makes successive inactive frames split into an appropriate number of successive inactive tatums at the frames associated with the blank state.

We also propose an efficient training method that works with the CTC and its variants. The objective function of the CTC2 to be maximized is given by the sum of the posterior probabilities of all possible alignment paths as in the CTC. Although it can thus be computed efficiently with dynamic programming (forward algorithm) in the analogy of the HMM to the HSMM, the backpropagation over the huge computation graph is computationally prohibitive. We thus perform the backpropagation along only an alignment path stochastically drawn according to the posterior probability with Gibbs sampling. Technically, we run the forward filtering-backward sampling in the evaluation mode to draw a path and then make a compact computation graph along the path in the training mode.

II. Related Work

This section reviews related work on ADT and that on end-to-end AMT.

A. Automatic Drum Transcription

Deep neural networks (DNNs) have intensively been used for ADT [1], [2], [5], [18]–[22]. In general, the spectrogram of an audio signal is used as input, and the annotated drum onset times are used as training data. For feature extraction, convolutional neural networks (CNNs) have commonly been used. Regularization based on prior information about drum scores [5] and refined network architectures [23] have also been attempted, resulting in improved performance of transcription. For converting DNN outputs into musical scores, we use beat information for quantization, and it has been reported that using temporal convolutional networks (TCNs) [24], [25] for beat tracking is effective. However, one problem with these methods is that they require as training data a sufficient amount of music spectrograms with precise annotations of drum onset times. To address this issue, the use of synthetic datasets [26], data augmentation [19], and unsupervised learning [27] have been proposed. Nevertheless, these approaches still face challenges in terms of robustness against real performances and the ability to handle variations in drum sounds.

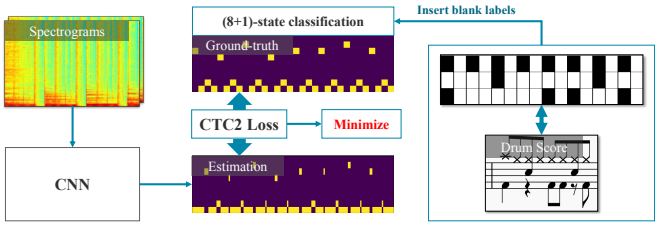

Fig. 2. The proposed ADT method based on the CTC2.

B. End-to-End Automatic Music Transcription

For end-to-end AMT that aims to directly estimate a musical score (a sequence of musical notations on the score), the attention mechanism [12] and the CTC [28], [29] have been investigated. In singing transcription based on the attention mechanism, the tempo consistency was taken into account [12], where the frame-to-tatum alignment is encouraged to be monotonic and regular by imposing a regularization term on the attention matrix. Such regularization, however, was found to prevent the initial progress of the training.

III. Proposed Method

This section describes the audio-to-score ADT method based on the CTC2-based end-to-end training (Fig. 2).

A. Problem Specification

Our goal is to estimate a drum score from a sequence of the stereo power spectra of a target musical piece, $\mathbf{X} \triangleq \{\mathbf{x}_t\}_{t=1}^{T}$ ($\mathbf{x}_t \in \mathbb{R}^{2F}$), where F is the number of frequency bins and T is the number of frames. We aim to estimate the presence or absence of the onsets of I drum instruments at the tatum level. In this study, we focus on the three common drum instruments: bass drum (BD), snare drum (SD), and hi-hats (HH) ($I = 3$). Let $y_n \in \{1, \ldots, K\}$ be the state of tatum n, which is defined as $y_n = 1 + 2^0\langle \mathtt{BD} \rangle_n + 2^1\langle \mathtt{SD} \rangle_n + 2^2\langle \mathtt{HH} \rangle_n$, where $K = 2^I = 8$, and $\langle \mathtt{DR} \rangle_n$ is a binary value indicating the presence or absence of an onset of DR at the tatum. Let $\mathbf{Y} \triangleq \{y_n\}_{n=1}^{N}$, where N is the number of tatums. The tatum is defined as the one-fourth of the beat, i.e., the tatum and beat correspond to the durations of the sixteenth and quarter notes, respectively.

B. Training and Inference

We describe the basic flow of end-to-end ADT. In addition to the main states indexed by $\{1, 2, \dots, K\}$ (Section III-A), we introduce the special blank state indexed by 0. Let $\boldsymbol{\pi} \triangleq \{\pi_t\}_{t=1}^{T}$ be a redundant state sequence, where $\pi_t \in \{0, \dots, K\}$ represents the state of frame t. We use a DNN with parameters θ that outputs the posterior probabilities of the $(K+1)$ states at the frame level, denoted by $\boldsymbol{\phi} \triangleq \{\phi_{k,t}\}_{k=0,t=1}^{K,T}$, where $\phi_{k,t}$ represents the probability of state k at frame t.

1) Training: Given a non-aligned pair of $\mathbf{X}$ and $\mathbf{Y}$ as training data, we train the DNN. Let $\mathcal{B}(\boldsymbol{\pi})$ be a one-to-one reducer that returns $\mathbf{Y}$ by annexing repeated states and removing all blank states from $\boldsymbol{\pi}$, e.g., $\mathcal{B}(01110112) = \mathcal{B}(01100122) = 112$. Let $\mathcal{B}^{-1}(\mathbf{Y})$ be a one-to-many expander that returns a set of all possible redundant state sequences that reduce to $\mathbf{Y}$, e.g., $\mathcal{B}^{-1}(112) = \{01110112, 1100122, \dots\}$. The DNN parameters θ are optimized such that the following posterior probability is maximized:

$$\begin{aligned} \mathcal{L} &= \log p(\mathbf{Y}|\mathbf{X}, \theta) \\ &= \log \sum_{\boldsymbol{\pi} \in \mathcal{B}^{-1}(\mathbf{Y})} p(\boldsymbol{\pi}|\mathbf{X}, \theta). \end{aligned} \tag{1}$$

2) Inference: Given $\mathbf{X}$, we estimate $\mathbf{Y}$ using a trained DNN with the parameters θ. The redundant state sequence $\boldsymbol{\pi}$ is obtained by selecting the most likely state at each frame:

$$\pi_t = \operatorname*{argmax}_k \phi_{k,t}. \tag{2}$$

The final output $\mathbf{Y}$ is given by $\mathbf{Y} = \mathcal{B}(\boldsymbol{\pi})$.

C. Conventional CTC

As a baseline, we briefly explain the training method based on the basic CTC. The posterior probability of an alignment path $\boldsymbol{\pi}$ in (1) is given by the product of the frame-wise posterior probabilities of the states as follows:

$$p(\boldsymbol{\pi}|\mathbf{X}, \theta) = \prod_{t=1}^{T} \phi_{\pi_t, t}. \tag{3}$$

The loss function $\mathcal{L}$ or $p(\mathbf{Y}|\mathbf{X}, \theta)$ in (1) can be computed efficiently with a dynamic programming technique called the forward algorithm as in the HMM. Let $\mathbf{Y}' \triangleq \{y'_s\}_{s=0}^{S}$ be an expanded state sequence obtained by inserting the $N-1$ blank states between the N states of $\mathbf{Y}$ and pushing the blank states to the front and back of $\mathbf{Y}$, i.e., $S = 2N+1$, $y'_{2n-1} = y_n$, and $y'_s = y_{\lfloor \frac{s}{2}+1 \rfloor}$. Let $\alpha_t(s)$ be the forward probability obtained by accumulating the posterior probabilities of all possible paths that align x_t with y'_s:

$$\alpha_t(s) = \sum_{\pi_{1:t} \in \mathcal{B}^{-1}(y_{1:\lfloor \frac{s}{2} \rfloor})} \prod_{\tau=1}^{t} \phi_{\pi_\tau, \tau}, \tag{4}$$

where $a_{1:t} \triangleq \{a_1, \dots, a_t\}$. Since an alignment path $\boldsymbol{\pi}$ is valid if the last frame x_T is aligned with the last non-blank symbol $y'_{S-1} = y_n$ or the last blank symbol y'_S, we have

$$p(\mathbf{Y}|\mathbf{X}, \theta) = \alpha_T(S-1) + \alpha_T(S). \tag{5}$$

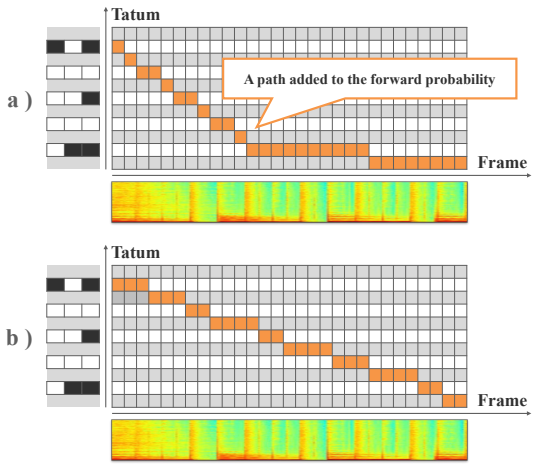

Fig. 3. Examples of the alignment path $\boldsymbol{\pi}$ estimated by a) the CTC- and b) CTC2-based training methods.

The forward probabilities can be computed recursively with the time complexity of $O(TS)$. First, we set the initial values:

$$\alpha_1(1) = \phi_{0,1}, \tag{6}$$

$$\alpha_1(2) = \phi_{y_1,1}, \tag{7}$$

$$\alpha_1(s) = 0, \forall s > 2. \tag{8}$$

We then use the following recursive formulas:

$$\alpha_t(s) = \begin{cases} \text{if } y'_s = \text{blank or } y'_{s-2} \\ \quad [\alpha_{t-1}(s) + \alpha_{t-1}(s-1)]\, \phi_{\pi_s, t}, \\ \text{else} \\ \quad [\alpha_{t-1}(s) + \alpha_{t-1}(s-1) + \alpha_{t-1}(s-2)]\, \phi_{\pi_s, t}. \end{cases} \tag{9}$$

In the inference stage, however, the optimal alignment path $\boldsymbol{\pi}$ estimated by (2) tends to deviate considerably from the diagonal line on the alignment map between the input sequence $\mathbf{X}$ and the estimated sequence $\mathbf{Y}'$ (Fig. 3-a). The durations of the N symbols in $\mathbf{Y} = \mathcal{B}(\boldsymbol{\pi})$ thus have a large variation, meaning that the tempo is allowed to frequently change at the tatum level in a musically-unnatural manner.

D. Training with Proposed CTC2

We then explain the training method based on the proposed CTC2 for explicit duration modeling with the constant tempo constraint (Fig. 4). Let $\mathbf{D} = \{d_n\}_{n=1}^{N}$ $(D_{\min} \le d_n \le D_{\max})$ denote the durations of the N symbols of $\mathbf{Y}$, where $D_{\min}$ and $D_{\max}$ are the minimum and maximum durations to be considered. When the frame shift is 10 [ms], the local tempo at tatum n is $1500/d_n$ [bpm]. Let $\mathcal{B}(\boldsymbol{\pi})$ be redefined as a one-to-one reducer that returns a pair $(\mathbf{Y}, \mathbf{D})$, e.g., $\mathcal{B}(01110112) = (112, 421)$, $\mathcal{B}(01100122) = (112, 412)$. Let $\mathcal{B}^{-1}(\mathbf{Y}, \mathbf{D})$ be redefined as a one-to-many expander that returns all possible sequences that reduce to $(\mathbf{Y}, \mathbf{D})$, e.g., $\mathcal{B}^{-1}(112, 412) = \{01110112, 1100122, \dots\}$. Note that even if both $\mathbf{Y}$ and $\mathbf{D}$ are given, $\mathcal{B}^{-1}(\mathbf{Y})$ may return multiple paths.

The posterior probability of $\mathbf{Y}$ in (1) is given by

$$p(\mathbf{Y}|\mathbf{X}, \theta) = \sum_{\mathbf{D}} p(\mathbf{Y}|\mathbf{X}, \theta, \mathbf{D}) p(\mathbf{D}), \tag{10}$$

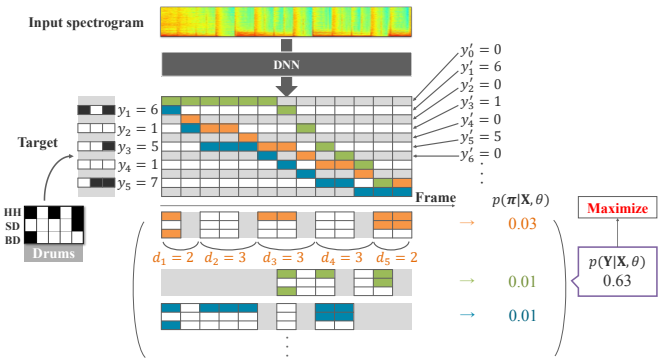

Fig. 4. The forward algorithm in the proposed CTC2-based training with explicit duration modeling.

where $p(\mathbf{Y}|\mathbf{X},\theta,\mathbf{D})$ is the posterior probability of $\mathbf{Y}$ conditioned by $\mathbf{D}$ and $p(\mathbf{D})$ is the generative probability of $\mathbf{D}$ given by a Markov model as follows:

$$p(\mathbf{D}) = p(d_1)\prod_{n=2}^{N} p(d_n|d_{n-1}), \tag{11}$$

$$p(d_1) \propto 1, \tag{12}$$

$$p(d_n|d_{n-1}) \propto \exp\left(-\lambda\left|\frac{d_n}{d_{n-1}} - 1\right|\right). \tag{13}$$

The loss function $\mathcal{L}$ or $p(\mathbf{Y}|\mathbf{X},\theta)$ in (1) can be computed efficiently as in the HSMM. Let $\alpha_t(s,d,c)$ be the forward probability obtained by accumulating the posterior probabilities of all possible paths that align x_t with y'_s:

$$\alpha_t(s,d,c) = \sum_{\pi_{1:t}\in\mathcal{B}^{-1}(y_{1:\lfloor\frac{s}{2}\rfloor},d_{1:\lfloor\frac{s}{2}\rfloor})} \prod_{\tau=1}^{t} \phi_{\pi_\tau,\tau}\cdot p(d_{1:\lfloor\frac{s}{2}\rfloor}), \tag{14}$$

$$p(d_{1:\lfloor\frac{s}{2}\rfloor}) = p(d_1)\prod_{n=2}^{\lfloor\frac{s}{2}\rfloor} p(d_n|d_{n-1}), \tag{15}$$

where d represents the duration of the current main state $y_{\lfloor\frac{s}{2}\rfloor}$ and c is a counter variable that is set to d when a new state starts and is then decremented until the state ends. We have

$$p(\mathbf{Y}|\mathbf{X},\theta) = \sum_{s=S-1}^{S}\sum_{d=D_{\min}}^{D_{\max}}\sum_{c=1}^{d}\alpha_T(s,d,c). \tag{16}$$

Note that if $\lambda = 0$ in (13), i.e., the durations of the output symbols are allowed to take any values with the same probability, i.e., $p(\mathbf{D}) = 1$, the CTC2 reduces to the CTC, i.e., (14) and (16) reduce to (4) and (5), respectively.

The forward probabilities can be computed recursively with the time complexity of $O(TSD^2)$, where $D \triangleq D_{\max} - D_{\min} + 1$. First, we set the initial values:

$$\alpha_1(1,d,c) = \phi_{0,1}, \forall d,c, \tag{17}$$

$$\alpha_1(2,d,c) = \phi_{y_1,1}, \forall d,c, \tag{18}$$

$$\alpha_1(s,d,c) = 0, \forall s > 2. \tag{19}$$

We then use the following recursive formulas:

$$\alpha_t(s,d,c) = \begin{cases} \text{if } d = c \\ \quad \text{if } y'_s = \text{blank} \\ \quad\quad 0, \\ \quad \text{else if } y'_s = y'_{s-2} \\ \quad\quad \sum_{d'}\alpha_{t-1}(s-1,d',1)\cdot\phi_{y'_s,t}\cdot p(d|d'), \\ \quad \text{else} \\ \quad\quad \sum_{d'}\bar{\alpha}_t(s,d,c)\cdot\phi_{y'_s,t}\cdot p(d|d'), \\ \text{else if } d > c \\ \quad \text{if } y'_s = \text{blank} \\ \quad\quad \bar{\bar{\alpha}}_t(s,d,c)\cdot\phi_{y'_s,t}, \\ \quad \text{else} \\ \quad\quad \alpha_{t-1}(s,d',c+1)\cdot\phi_{y'_s,t}, \\ \text{else} \\ \quad 0, \end{cases} \tag{20}$$

$$\bar{\alpha}_t(s,d,c) = \alpha_{t-1}(s-1,d,1) + \alpha_{t-1}(s-2,d,1), \tag{21}$$

$$\bar{\bar{\alpha}}_t(s,d,c) = \alpha_{t-1}(s,d,c+1) + \alpha_{t-1}(s-1,d,c+1). \tag{22}$$

In the inference stage, the optimal alignment path $\boldsymbol{\pi}$ estimated by (2) tends to roughly follow the diagonal line on the alignment map between the input sequence $\mathbf{X}$ and the estimated sequence $\mathbf{Y}'$ (Fig. 3-b). The durations $\mathbf{D}$ of the N symbols of $\mathbf{Y}$, which are given by $(\mathbf{Y},\mathbf{D}) = \mathcal{B}(\boldsymbol{\pi})$, are thus kept almost constant. This enables the active and inactive states (tatums) to have similar durations.

The CTC2, however, considers several orders of magnitude larger number of possible paths than the CTC and thus makes the exact backpropagation prohibitive in practice. Note that the forward computation in the inference mode without constructing the computation graph can still be performed quickly.

E. Computationally-Efficient Training

We propose an efficient training method that can be applied to the CTC2 (and the CTC) at a minimum sacrifice of performance. Instead of backpropagating the error through all possible paths on the huge computation graph constructed by the forward algorithm, we focus on only the most likely path found by the Viterbi algorithm or a path randomly selected according to its posterior probability with the Gibbs sampling. To determine such a path, the forward and backward recursions can be executed faster in the inference mode. Since the Gibbs sampling stochastically generates likely paths not limited to the most likely one, it is expected to be more robust against local optima than the Viterbi algorithm. Let $\mathbf{Z} \triangleq \{z_t\}_{t=1}^{T}$ be a latent state sequence, where $z_t \triangleq (s_t,d_t,c_t)$. An alignment path $\boldsymbol{\pi}$ is uniquely determined by $\mathbf{Z}$.

1) Viterbi Algorithm: In the forward recursion, the forward probabilities $\{\alpha_t(z_t)\}_{t=1}^{T}$ are computed as described in Section III-D except that the sum operations over d' of (20) and the additions of (21) and (22) are replaced with the max operations, where the indices and terms that take the maximum values are memorized. In the backward recursion, the states of most likely $\mathbf{Z}$ are determined in the reverse order by backtracing the memorized path from z_T such that $\alpha_T(z_T)$ is maximized, where $s_T \in \{S-1,S\}$, $d_T \in \{D_{\min},\ldots,D_{\max}\}$, and $c_T \in \{1,\ldots,d_T\}$.

2) Gibbs Sampling: We use the forward filtering-backward sampling algorithm, which was originally proposed for sampling the latent sequence of an HMM or HSMM [30]. In the forward filtering, the forward probabilities are computed as described in Section III-D. In the backward sampling, the states of $\mathbf{Z}$ are sampled in the reverse order according to

$$p(z_T) \propto \alpha_T(z_T), \tag{23}$$

$$p(z_t|z_{t+1:T}) \propto \alpha_t(z_t) A_{z_t z_{t+1}} \ (t = \{T-1, \ldots, 1\}), \tag{24}$$

where $A_{z_t z_{t+1}}$ represents the transition probability from z_t to z_{t+1} obtained by normalizing the following matrix:

$$A'_{z_t z_{t+1}} = \begin{cases} p(d_t|d_{t+1}) & \text{if condition 1 holds,} \\ 1 & \text{if condition 2 holds,} \\ 0 & \text{otherwise,} \end{cases} \tag{25}$$

condition 1: $c_t = 1$ and ($y'_s =$ blank and $s_{t+1} = s_t + 1$ or $y'_s \neq$ blank and $y'_s \neq y'_{s+2}$ and $s_{t+1} = s_t + 2$),

condition 2: $d_t > c_t$ and $d_t = d_{t+1}$ and $c = c_{t+1} + 1$ and ($y'_s =$ blank and $s_{t+1} = s_t + 1$ or $s_{t+1} = s_t$).

IV. Evaluation

This section reports a comparative experiment conducted for evaluating the performance of the proposed ADT method and the effectiveness of the efficient training.

A. Experimental Conditions

The 100 songs of the RWC Music Database: Popular Music [31] were randomly split into 60 and 40 songs for training and test data, respectively. The stereo signals of each song sampled at 44.1 kHz were analyzed by short-time Fourier transform (STFT) with a window size of 1024 pts ($F = 513$) and a hop size of 441 pts (10 [ms]). The left and right channels were concatenated to form the input data $\mathbf{X}$. The tempo was assumed to be between 50 and 250 [bpm], i.e., the duration of a tatum was between $D_{\min} = 6$ to $D_{\max} = 30$.

We trained a convolutional recurrent neural network (CRNN) with the basic CTC or the proposed CTC2. It has 11 convolutional layers with a kernel size of 3×3, a padding size of 1×1, and a stride of 1 yielding a (512×4)-dimensional feature map, on which a dropout of 30% was applied before feeding it into a linear layer, followed by three bi-directional long short-term memory (BLSTM) layers with 200-dimensional hidden states. We used AdamW [32] with a learning rate $\gamma = 0.001$, a weight decay parameters $\lambda = 10^{-4}$, $\beta_1 = 0.9$, $\beta_2 = 0.98$, and $\varepsilon = 10^{-9}$ for optimization. When the Viterbi algorithm or the Gibbs sampling (Section III-E) was used with the CTC, the basic training (Section III-C) was performed for initialization. For the CTC2, the basic training could not be tested due to the huge computational cost.

For comparison, we implemented to test a recent audio-to-MIDI transcription method based on multi-task learning that jointly detects drum onset times and beat times at the frame level [2]. This method was trained using music signals with frame-level onset annotations, whereas our method was trained end-to-end using music signals with *non-aligned* scores. For MIDI-to-score transcription, the detected drum onset times were quantized on the tatum grid made of the beat times estimated by an HMM-based beat tracker [3] as post-processing.

Our end-to-end transcription method with the CTC or CTC2 and the cascading method mentioned above [2], [3] were evaluated in terms of the tatum- and frame-level accuracies. For tatum-level evaluation of estimated *scores*, we used the tatum error rate (TER), an edit distance similar in spirit to the word error rate (WER) in speech recognition, as follows:

$$\mathrm{TER} = \frac{\#\mathrm{insersion} + \#\mathrm{deletion} + \#\mathrm{substitution}}{N}, \tag{26}$$

where $\#$insersion, $\#$deletion, $\#$substitution represent the numbers of insertion, deletion, and substitution errors, respectively, and N represents the total number of tatums in the ground-truth data. For frame-level evaluation of estimated *onset times*, we set the error tolerance to 70 [ms]. Note that the initial frames of the active states (tatums) determined by the estimated alignment path $\boldsymbol{\pi}$ were regarded as drum onset times for convenience in our end-to-end method. Since those onset times tend to have a constant offset from the ground-truth onset times, the best offset was found for each song such that the performance was maximized for fair comparison.

TABLE I
THE TATUM- AND FRAME-LEVEL EVALUATION RESULTS.

Method	Tatum error rate ↓			F-measure ↑		
	Basic	Viterbi	Gibbs	Basic	Viterbi	Gibbs
CTC [14]	34.4	35.1	35.6	79.4	78.6	76.1
CTC2 (ours)	-	**33.8**	**33.8**	-	79.2	79.0
Vogl et al. [2]		34.5			**83.1**	

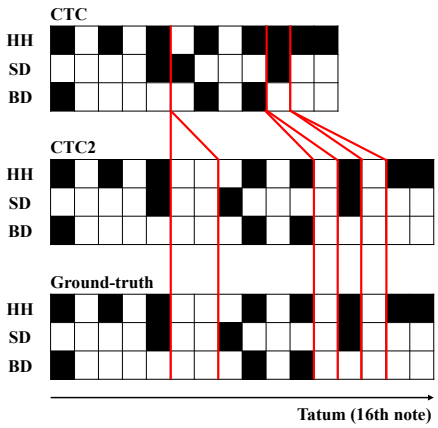

Fig. 5. Examples of tatum-level drum score fragments estimated by the CRNN trained with the basic CTC or the proposed CTC2. Whereas the CTC often failed to detect inactive states, the CTC2 correctly detected them.

B. Experimental Results

As shown in Table I, the CTC2 steadily outperformed the CTC in both metrics. Although the quantitative difference was small, the CTC2 yielded considerably better drum scores in the naturalness of rhythm despite the fact that the metrical structure was not considered. As shown in Fig. 5, the CTC2 successfully estimated a correct number of inactive tatums,

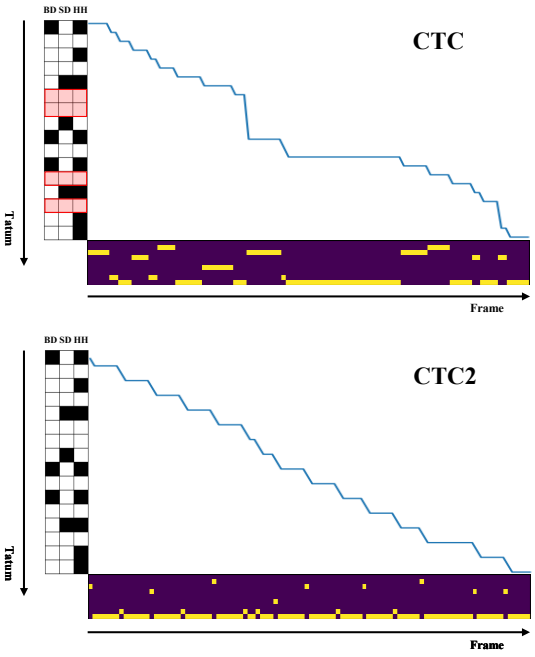

Fig. 6. Examples of alignment paths estimated by the CRNN trained with the basic CTC or the proposed CTC2 in the training phase. Whereas the CTC yielded a path with sudden tempo changes, the CTC2 yielded a diagonal path with an almost constant tempo.

which were missed by the CTC, between active tatums thanks to the constant tempo constraint. As shown in Fig. 6, in the training phase based on the forced alignment between the estimated and ground-truth state sequences, the CTC2 yielded an alignment path with an almost constant grade (tempo) around the diagonal line on the lattice. The CTC, in contrast, allowed an alignment path to discontinuously and frequently change the grade in a musically-unnatural manner. The Viterbi algorithm and the Gibbs sampling worked comparably in performance (Table I) and were several orders of magnitude faster than the basic backpropagation on the entire computation graph at a minimum sacrifice of performance (Fig. 7).

Compared with the conventional cascading method [2], our end-to-end method with the CTC2 performed slightly better by 0.7 pts in the TER, but worse by 6.0 pts in the F-measure. Note that the frame-level metric is advantageous for audio-to-MIDI transcription methods that use precise frame-level onset annotations for training. Considering that our method can be trained end-to-end with non-aligned audio-score pairs and does not aim at frame-level onset detection (the alignment path does not necessarily indicate precise onset times), this result is still considered to be promising.

V. Conclusion

In this paper, we proposed an end-to-end ADT method based on the CTC with constant tempo constraint, CTC2 in short, that estimates a sequence of tatum-level drum score fragments from a music signal. Although the loss function can be computed efficiently as in the vanilla CTC, the backpropagation

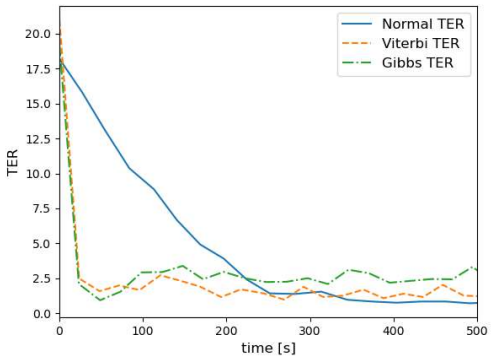

Fig. 7. Comparion of convergence speeds achieved by the basic training, the Viterbi algorithm, and the Gibbs learning.

over the huge computation graph made by the forward algorithm is computationally prohibitive. To solve this problem, we proposed a novel efficient training method that performs the backpropagation through only an alignment path found by the Viterbi algorithm or stochastically drawn with Gibbs sampling. Since non-aligned drum scores are easier to collect than labor-intensive frame-level onset annotations, the proposed end-to-end ADT method has a large potential for performance improvement based on large-scale training.

The CTC2 is a general technique for explicit duration modeling in a monotonic sequence-to-sequence mapping task not limited to ADT. It can be customized by formulating a duration model according to the task. In handwritten character recognition [33], for example, the CTC with constant "size" constraint would be useful for encouraging each character to have almost the same size. The Viterbi algorithm and the Gibbs sampling can also be applied to a wide range of tasks in various fields for accelerated CTC-based training. We are currently investigating how to effectively use the Viterbi algorithm in the inference phase as well as the training phase.

***Abstract*—This paper describes a data-driven music structure analysis (MSA) method that performs segmentation and clustering of musical sections for a music signal. Since the intra-section homogeneity and inter-section difference are important clues for MSA, most studies on MSA have focused on self-similarity matrices (SSMs) computed from various acoustic features of a music signal. The performance of this approach, however, might be limited because the acoustic features used for computing SSMs are designed manually, and multiple SSMs are often integrated in a heuristic manner. To overcome these limitations, we propose a method that learns latent features useful for MSA with a stack of convolution-augmented multi-head self-attention (CAMHSA) layers that compute and fuse multiple self-attention maps representing multifaceted self-similarity. The estimated features are then clustered into an appropriate number of sections with a Gaussian mixture model (GMM). In the segmentation and clustering tasks, the proposed method outperformed baseline methods based on hand-crafted SSMs. In particular, it achieved state-of-the-art performance on the segmentation task. We found that the internal attention maps represent the section boundaries at the fine and course levels.**

I. Introduction

Audio-based music structure analysis (MSA) aims to split a musical recording into musically-meaningful segments based on the homogeneity and heterogeneity of the musical contents, and then assign a letter (e.g., A, B, or C) or functional label (e.g., verse, chorus, or bridge) to each of the segments. The process of MSA can be divided into two sub-tasks: *segmentation* and *clustering*. The former aims to detect the boundaries of musical sections. The latter aims to categorize the segments into multiple groups. In the field of music information retrieval (MIR), the two tasks are often tackled separately.

Given the repetitive nature of music, the self-similarity matrix (SSM) has been a common feature for tackling MSA [1]–[3], as repetitions and musically homogeneous parts typically result in diagonals and block patterns on the SSM. Nevertheless, the choice of audio representation for computing the SSM has a crucial impact on the performance of MSA. For instance, using timbre- or harmony-related features might yield two different SSMs highlighting possibly two distinct temporal structures for the same audio signal, as depicted in Fig. 1. Considering the multiple aspects of similarity, one may compute multiple SSMs from various kinds of acoustic features [4]. Several techniques have also been proposed for fusing different aspects of similarity [5], [6]. Such an approach, however, has a performance limitation due to a finite number of hand-crafted features used for computing SSMs. In addition, segmentation and clustering algorithms should be tailor-made according to the characteristics of each SSM.

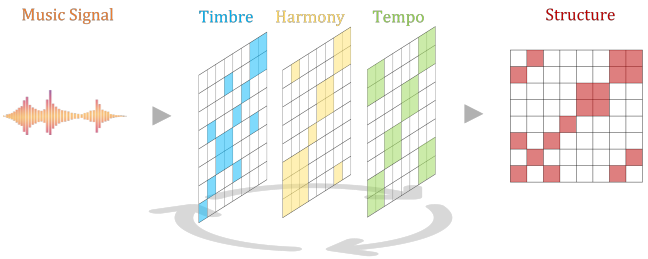

Fig. 1: The self-similarity of a music signal varies with the aspect across musical elements (e.g., timbre, harmony, and tempo). Learning a multifaceted view of self-similarity is thus crucial for music structure analysis.

To overcome these limitations, we propose an MSA method that performs segmentation and clustering on latent features learned by a deep neural network (DNN) with a convolution-augmented multi-head self-attention (CAMHSA) mechanism, an extension of the multi-head self-attention (MHSA) mechanism [7]. The main motivation for our study is that the self-attention maps computed internally through a stack of MHSA layers (i.e., the transformer encoder [7]) are expected to represent multifaceted self-similarity at different abstract levels. Our method is capable of learning to fuse such self-attention maps with additional convolutional operations in each layer. Specifically, the DNN is trained in a supervised manner to output latent features with which section boundaries are detected accurately and from which the derived SSM is made close to the ground-truth SSM. The latent features are then used for an unsupervised clustering method based on the Gaussian mixture model (GMM).

The main contributions of this study are twofold. We theoretically and experimentally show the effectiveness of the CAMHSA in learning a multifaceted self-similarity for MSA. We achieved a state-of-the-art performance of segmentation.

II. Related Work

This section briefly introduces audio-based music structure analysis and the self-attention mechanism.

A. Music Structure Analysis

Previous research in MIR often tackles MSA from either the segmentation or the clustering aspects. For the segmentation task, a bunch of deep learning approaches is proposed to identify musical boundaries within a given piece [8]–[12]. This task is often formulated as a binary classification problem, where spectrogram-based features, such as chromagram and mel-spectrogram, and SSMs derived from these features are commonly used as the inputs. Considering the size of SSMs grows quadratically with the duration of the corresponding audio signal, self-similarity lag matrices (SSLMs) [13] can be used instead to represent the similarities of each audio frame to a limited number of the preceding frames.

In contrast, the clustering task is typically approached as a clustering problem. This involves utilizing frame-wise acoustic features or affinity matrices (either hand-crafted or learned) as inputs for a clustering algorithm or a matrix decomposition method in order to group the audio frames [5], [6], [14]. Alternatively, this task can be formulated as a classification problem, and a model is employed to label each audio frame with a predefined vocabulary [15]. With manually annotated datasets such as the SALAMI dataset [16] and the Beatles dataset (released originally in the Isophonics dataset [17]), previous studies mostly applied supervised learning frameworks to the segmentation and clustering tasks. Recently, contrastive learning approaches are also explored in learning audio representations for MSA in an unsupervised or self-supervised fashion [18], [19]. For a detailed review of the audio-based MSA in MIR, we refer readers to [20].

B. Self-Attention Mechanism

The intra-attention mechanism [21], [22], also known as the *self-attention* (SA) [7], is proposed to encode compositional relationships between a set of elements (e.g., words of a sentence), and has demonstrated its effectiveness in various research fields such as natural language processing (NLP) [23]–[25] and computer vision (CV) [26]–[28]. In the field of MIR, several studies have utilized the SA [29]–[31]. However, the potential of the SA for MSA has yet to be investigated.

Formally, given a sequence of t elements with d-dimensional features, $\mathbf{X} \in \mathbb{R}^{t \times d}$, the SA yields a new representation of the sequence, i.e., $\mathrm{SA}(\mathbf{X}) \in \mathbb{R}^{t \times d}$, by internally computing an affinity matrix or an *attention map*, $\mathbf{A} \in \mathbb{R}^{t \times t}$, indicating the similarity between each pair of the elements in the sequence as follows:

$$\begin{aligned} \mathrm{SA}(\mathbf{X}) &= \mathbf{A} f_v(\mathbf{X}) \\ &= \mathrm{softmax}(f_q(\mathbf{X}) f_k(\mathbf{X})^{\mathrm{T}}) f_v(\mathbf{X}), \end{aligned} \tag{1}$$

where $f_{\{q,k,v\}} \colon \mathbb{R}^{d_{in}} \to \mathbb{R}^{d_{out}}$ are learnable layers projecting the *query*, *key*, and *value* [7] (all denote the same input for self-attention) to a common latent space in which similarity is measured and the input is represented. With this definition, the attention map can be regarded as a generalization of a softmax-normalized SSM computed in the latent space, and it becomes an exact SSM if $f_q(\cdot) = f_k(\cdot)$.

Based on the idea of the SA, the multi-head self-attention (MHSA) mechanism [7] consists of multiple SAs for extracting multifaceted similarity information from various representation subspaces as follows:

$$\mathrm{MHSA}(\mathbf{X}) = [\mathrm{SA}(\mathbf{X}^{(1)}), \cdots, \mathrm{SA}(\mathbf{X}^{(h)})]\mathbf{W}, \tag{2}$$

where $h \in \mathbb{N}^+$ is the number of heads, $\mathbf{X}^{(\mathrm{h}=1:h)} \in \mathbb{R}^{t \times \frac{d}{h}}$ is a division of $\mathbf{X}$ within the feature dimension, $[\ ]$ denotes a matrix concatenation along the feature dimension, and $\mathbf{W} \in \mathbb{R}^{d \times d}$ is a learnable parameter used to fuse information from the attention heads. In practice, the attention heads can be computed in a parallel manner via manipulating the dimensionality of $f_{\{q,k,v\}}(\mathbf{X})$. Let $\hat{f}_{\{q,k,v\}}(\mathbf{X}) \in \mathbb{R}^{h \times t \times \frac{d}{h}}$ be the dimensionality-manipulated tensor of $f_{\{q,k,v\}}(\mathbf{X})$. We can rewrite (2) as follows:

$$\mathrm{MHSA}(\mathbf{X}) = \mathrm{restore}(\hat{\mathbf{A}} \hat{f}_v(\mathbf{X}))\mathbf{W}, \tag{3}$$

where $\hat{\mathbf{A}} = \mathrm{softmax}(\hat{f}_q(\mathbf{X}) \hat{f}_k(\mathbf{X})^{\mathrm{T}})$ and $\mathrm{restore}(\cdot)$ get back the dimensionality from $\mathbb{R}^{h \times t \times \frac{d}{h}}$ to $\mathbb{R}^{t \times d}$.

The MHSA can attend to various relations in different latent spaces by referring to multiple SSMs. Previous studies have pointed out that the attention heads of the MHSA are capable of capturing different types of implicit relationships between the elements of a sequence [32], [33]. The MHSA mechanism is thus favorable for MSA as it can alleviate the feature selection issue with learned features and affinity matrices.

III. Proposed Method

To cope with the feature selection issue when employing SSMs for MSA, we propose the *convolution-augmented multi-head self-attention*, which learns to *construct* and *fuse* multiple affinity matrices. Besides, we tackle the MSA with a two-stage framework. In the first stage, we employ a DNN equipped with the proposed attention mechanism to jointly predict musical boundaries and frame-wise representations for a given input. In the second stage, we obtain structural groups by clustering the frame-wise representations.

A. Data Representation

The input is a standardized audio signal sampled at 32 kHz. Three types of acoustic features are extracted from the signal: *mel-spectrogram*, *chromagram*, and *tempogram* [34]. For mel-spectrogram ($\mathbf{X}_m \in \mathbb{R}^{t \times 80}$), we use a mel-scaled filterbank of 80 triangular filters from 80 Hz to 16 kHz and scale magnitudes logarithmically. For chromagram ($\mathbf{X}_c \in \mathbb{R}^{t \times 12}$), the constant-Q spectrogram of 12 bins per octave is used. For tempogram ($\mathbf{X}_t \in \mathbb{R}^{t \times 384}$), the rhythmic content is encoded via the local auto-correlation of the onset strength envelope. All the features are calculated with *librosa* [35]. To analyze the entire piece once, which is crucial for learning long-term music structure, we compute all three acoustic features with a large hop size of

1600 points and downsample them with a factor of 10 using a median filter, resulting in a frame size of 0.5 sec.

The boundary annotation of each piece is given as a binary sequence ($\mathbf{Y}_b$) where 1 indicates a boundary and 0 otherwise; for the clustering task, the annotations of section names are converted into a finite alphabet ($\mathbf{Y}_s$) and the variation signs (e.g., '′' and '″') are ripped off. For instance, the annotation `[verse,verse′,chorus]` would become `[A,A,B]`.

B. Convolution-Augmented Multi-Head Self-Attention

While the MHSA is capable of capturing various relantionships between a set of elements, the calculations of the attention heads are independent of each other. More precisely, each attention map is computed individually without being related to other attention maps. In fact, it has been demonstrated that the tasks of MSA can benefit from integrating multiple affinity matrices into a united representation [6], [9]. For this reason, we propose to equip the MHSA with convolutional layers to fuse information from multiple attention maps. Concretely, we perform 2-D convolutions on the stack of the attention maps before the softmax function is applied. The convolution-augmented MHSA, denoted by $\mathrm{CAMHSA}(\mathbf{X}) \in \mathbb{R}^{t\times d}$, can thus be formulated as follows (Fig. 2):

$$\mathrm{CAMHSA}(\mathbf{X}) = \mathrm{restore}(\hat{\mathbf{A}}^{*} f_v(\hat{\mathbf{X}}))\mathbf{W}, \tag{4}$$

where $\hat{\mathbf{A}}^{*} = \mathrm{softmax}(\mathrm{conv}(f_q(\hat{\mathbf{X}}) f_k(\hat{\mathbf{X}})^{\mathrm{T}}))$ is an attention map and $\mathrm{conv}(\cdot)$ is a stack of two successive convolutional layers with a layer normalization [36] in between.

In fact, a recent work, i.e., the Conformer [37], has explored the combination of CNNs and the MHSA mechanism for modeling both local and global dependencies of a given sequence. Our approach differs from this work in how convolutions are employed. As shown in Fig. 3, the Conformer employs a 1-D CNN *outside* the MHSA block to capture local dependencies of the output sequence, whereas the CAMHSA performs 2-D convolutions *inside* the MHSA block to merge structural information of different attention maps. By utilizing convolutions, the CAMHSA can learn the correlations among various attention maps, leading to the enhancement of the attention heads.

C. Model Architecture

The model for MSA is composed of three parts, as shown in Fig. 4. The three types of input features are separately encoded by a 2-D CNN. The encoded features, $\mathbf{E}_{\{m,\ c,\ t\}} \in \mathbb{R}^{t\times d}$ for $\mathbf{X}_{\{m,\ c,\ t\}}$ respectively, are fused with another 2-D CNN. The fused feature, $\mathbf{E} \in \mathbb{R}^{t\times d}$, is then fed into a 2-layer transformer encoder with 8 attention heads [7], in which the MHSA mechanism is replaced by the CAMHSA. Finally, the latent representation by the transformer encoder, $\mathbf{H} \in \mathbb{R}^{t\times d}$, is used to predict segmentation, $\mathbf{P}_b \in \mathbb{R}^{t}$, for the segmentation task and frame-wise representations, $\mathbf{P}_s \in \mathbb{R}^{t\times d}$, for the clustering task with two 1-D CNNs. We set $d = 80$ for the model. The details of the computation blocks are depicted in Fig. 5 and elaborated as follows.

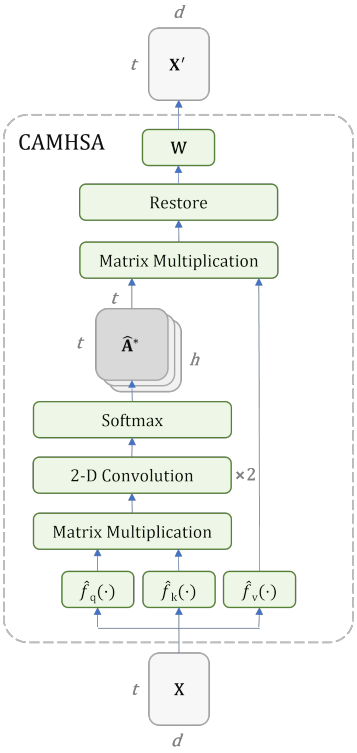

Fig. 2: Schematic diagram of the CAMHSA mechanism. The CAMHSA transforms $\mathbf{X}$ into $\mathbf{X}'$ similarly to the MHSA but with the addition of 2-D convolutions fusing information of the attention maps after the first matrix multiplication.

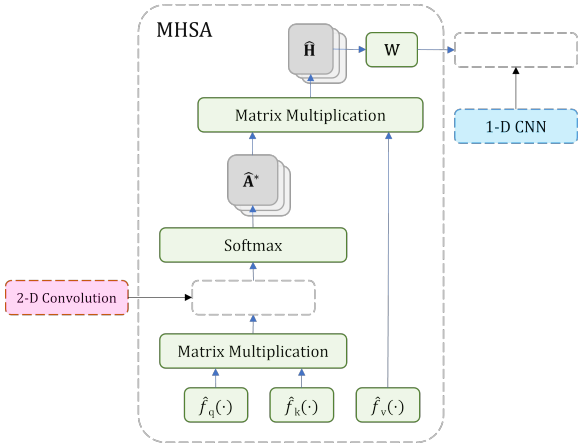

Fig. 3: Comparison between the CAMHSA and the Conformer. The CAMHSA improves the MHSA by performing 2-D convolutions after the matrix multiplication, whereas the Conformer utilizes a 1-D CNN for the MHSA output.

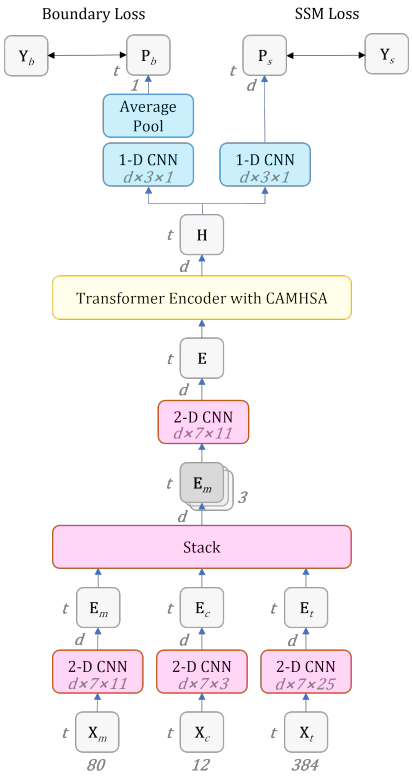
1) 2-D CNN (Fig. 5c): The 2-D CNNs are composed of three successive 2-D convolutions, each of which is followed by AdaNorm [38], the ReLU activation, and the *Squeeze-and-Excitation* (SE) operation [39], two branches of the dimension reduction performing *Max Pool* and *Dense* on the inner dimension, and a fusion of the two branches (*Dense & AdaNorm*



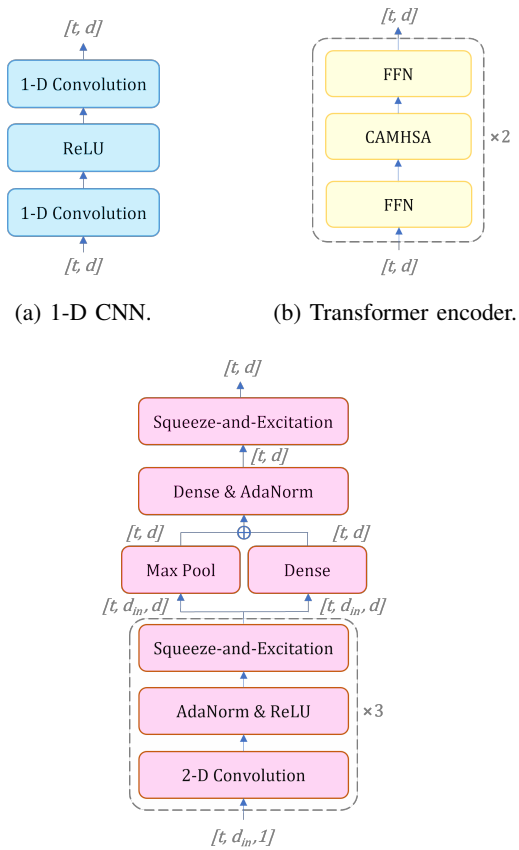


Fig. 4: Proposed model for MSA. The 2-D CNNs are used to encode and fuse the inputs; the Transformer encoder captures structural information via the CAMHSA mechanism; finally, the 1-D CNN functions as an output layer for boundary prediction. For each CNN, the number of convolution filters (c) and the kernel size, represented by height (h) and width (w), are denoted as $c \times h \times w$.

(a) 1-D CNN. (b) Transformer encoder.

(c) 2-D CNN.

Fig. 5: Computation blocks of the segmentation model. The MHSA block of the Transformer encoder is replaced by the CAMHSA. The dimensionality is indicated in the brackets.

followed by *SE*). The two branches of the dimension reduction function as global pooling layers summarizing the information of the *feature dimension* of the input (i.e., d_{in} in the figure).

2) Transformer Encoder with CAMHSA (Fig. 5b): We use a variant of the transformer architecture, i.e., the Macaron Net [37], [40], which has two feed-forward networks (FFNs) sandwiching the CAMHSA. Moreover, we employ relative positional embeddings to represent the distances between elements [41]. Besides, the residual connection and layer normalization techniques are also utilized in both the CAMHSA and the FFN (as used in the transformer blocks) despite not being displayed in the figure.

3) 1-D CNN (Fig. 5a): The 1-D CNNs consist of two 1-D convolutions with a ReLU activation in between.

D. Loss Functions

We employ two losses to jointly optimize the model (Fig. 4). The *boundary loss* is used for the segmentation task, while the *SSM loss* is used for the clustering task. The total loss is thus a summation of the two losses:

$$\text{Total Loss} = \text{Boundary Loss} + \text{SSM Loss}. \tag{5}$$

The boundary loss is a combination of the binary cross entropy loss (BCE) and the dice loss (DL) [42]:

$$\text{Boundary Loss} = \text{BCE}(\mathbf{P}_b, \mathbf{Y}_b) + \text{DL}(\mathbf{P}_b, \mathbf{Y}_b), \tag{6}$$

where $\text{DL}(\mathbf{A}, \mathbf{B}) = 1 - \frac{2 \times \sum \mathbf{A} \odot \mathbf{B}}{\sum \mathbf{A}^2 + \sum \mathbf{B}^2}$ ($\odot$ denotes the Hadamard product). We integrate the DL with the commonly used BCE, for it allows the model to pay attention to the overlapped regions between the predicted segmentation and the ground truth annotation [43], [44], and thus can alleviate the data imbalance issue in the segmentation task (i.e., the imbalance between boundary and non-boundary audio frames).

In contrast, we employ the SSM loss to regulate the predicted features, i.e., $\mathbf{P}_s$. Specifically, we compute two SSMs, $\mathbf{M}^{\mathbf{P}_s} \in \mathbb{R}^{t \times t}$ and $\mathbf{M}^{\mathbf{Y}_s} \in \mathbb{R}^{t \times t}$, with $\mathbf{P}_s$ and $\mathbf{Y}_s$ respectively, and then calculate the mean squared error:

$$\text{SSM Loss} = \frac{1}{t^2} \sum_{i,j=1:t} (\mathbf{M}^{\mathbf{P}_s} - \mathbf{M}^{\mathbf{Y}_s})^2, \tag{7}$$

where $\mathbf{M}_{ij}^{\mathbf{P}_s}$ is a similarity score ($\in [0, 2]$) measuring the normalized Euclidean distance between $\mathbf{P}_{s,i}$ and $\mathbf{P}_{s,j}$, and $\mathbf{M}_{ij}^{\mathbf{Y}_s} = 2$ if $\mathbf{Y}_{s,i} = \mathbf{Y}_{s,j}$ otherwise 0.

E. Clustering

We use the learned features by the proposed model, i.e., $\mathbf{P}_s$, to obtain section groups. We first perform the principal component analysis (PCA) to reduce the feature dimension of $\mathbf{P}_s$ from 80-D to 60-D. The reduced features are then clustered with Gaussian mixture models (GMMs). Specifically, we employ a set of GMMs with the number of mixture components ranging from 1 to k_{max} for each input piece, and then choose the best GMM based on the Bayesian information criterion (BIC) [45]. Finally, given the boundary prediction, we smooth the clustering results by reassigning the most common label in each segment to all frames within the segment.

IV. Evaluation

In this section, we present the comparative experiment conducted to evaluate the performance of the proposed method in terms of segmentation and clustering.

A. Data

To evaluate the proposed method, two datasets have been included. 1) The Beatles-TUT dataset[1] is a refined version of the Beatles dataset [17] by members of the Tampere University of Technology. It contains 174 songs by the Beatles and the corresponding *flat* (one-level, *upper*) annotations of structure. 2) The SALAMI dataset [16] is the largest publicly available set which contains *hierarchical* (two-level, *upper* and *lower*) annotations for 1,359 tracks. We use version 2.0 of the dataset[2] for the evaluation. We acquired 441 audio tracks from the Internet Archive[3] and found 555 matching tracks on YouTube[4].

We train and evaluate the proposed model with the two datasets individually. In the case of the Beatles-TUT dataset, we exclude 14 songs from the first album for testing and use the remaining 160 songs for training purposes. As for the SALAMI dataset, we utilize the 555 tracks from YouTube for training and the 441 tracks from the Internet Archive for testing. For both datasets, we augment the training data by 3 times via shifting the pitch of each track by ± 1 semitone.

B. Evaluation Metrics

For the segmentation task, we report the Hit Rate measure [46] with a time tolerance of ± 0.5 sec and ± 3 sec (which are the most frequently used values in the literature). This metric computes precision (P), recall (R), and F1 score (F1) by checking if a predicted boundary is close enough to an annotated boundary according to the given time tolerance.

For the clustering task, two metrics are employed. The *pairwise agreement* [47] is used to evaluate the frame-clustering segmentation regarding a flat annotation, while the *L-measure* [48] assesses all segmentation levels as a whole concerning a hierarchical annotation. Similarly to the Hit Rate measure, both the pairwise agreement and the L-measure compute the P, R, and F1 scores. Note that the L-measure is applied to the SALAMI dataset only as there are no hierarchical annotations in the Beatles-TUT dataset. All the evaluations are done using the *mir_eval* package [49].

C. Experiment Settings

The proposed model is evaluated separately on the segmentation task and the clustering task. Since the SALAMI dataset contains annotations at two structure levels, we equip the proposed model with an additional branch when training with the SALAMI dataset. Concretely, we create a branch by duplicating all computation blocks following the stack operation (see Fig. 4), while the first three 2-D CNNs are shared by the branches.

To validate our approach regarding the CAMHSA mechanism, we build a baseline model by removing the transformer encoder from the proposed model and including as additional inputs the SSMs derived from $\{\mathbf{X}_m, \mathbf{X}_c, \mathbf{X}_t\}$. Since it is memory-consuming to apply deep learning models to multiple track-level SSMs, we alternatively build three baseline models (denoted as *baseline-*$\{m, c, t\}$), each of which uses one of $\{\mathbf{X}_m, \mathbf{X}_c, \mathbf{X}_t\}$ and its corresponding SSM as inputs.

In comparison to previous work using supervised learning approaches, we report the best results in [9] (segmentation on SALAMI) and [11] (segmentation on Beatles and the upper level of SALAMI). To our knowledge, the former achieves the best segmentation performance on the SALAMI dataset while the latter on the Beatles dataset. We also report the results by [19] (segmentation and clustering on both Beatles and SALAMI) in comparison with the unsupervised learning approach. Note that the comparisons to these works should be taken with a grain of salt for there are many differences between these works and ours, such as dataset version (e.g., Beatles-Isophonics and Beatles-TUT), data usage (e.g., training and testing sets), and data representation.

Finally, we conduct ablation studies on the CAMHSA mechanism and the loss functions. Specifically, we build a model (denoted as *proposed w/o conv*) by replacing the CAMHSA blocks of the proposed model with the MHSA to validate the incorporation of convolutions; we also train the proposed model without including the DL in the boundary loss (denoted as *proposed w/o dl*) to investigate whether the DL provides any benefits to the segmentation task.

D. Results and Discussions

1) The Segmentation Task (Table I): On the Beatles-TUT dataset (Table Ia), our approach consistently outperformed all the baselines. Likewise, on the SALAMI dataset (Table Ib), our method was superior in all cases except for *Hit Rate(3)* at the lower level. When compared with the previous works, our method achieved new state-of-the-art segmentation performances on both datasets. More strikingly, our approach can rival the unsupervised approach [19] where the amount of audio tracks for training is two orders of magnitude larger than ours. Based on these findings, it appears that acquiring knowledge of multifaceted self-similarity is a more effective approach than relying on pre-established affinity matrices.

(b) Evaluation on the SALAMI dataset.

2) The Clustering Task (Table II): Similarly to the segmentation task, our approach surpassed the baselines in almost all cases. In general, the clustering performance on the SALAMI dataset (Table IIb) is worse than that on the Beatles-TUT (Table IIa) since the SALAMI dataset is more diverse in terms of music genres and styles. Upon evaluation, it is apparent that clustering at the lower level is more challenging than at the upper level for the SALAMI dataset. This can be attributed to the greater number of boundaries in the lower level compared to the upper level. Furthermore, the pairwise agreement measure is sensitive to the precise placement of the boundaries between the prediction and the ground truth [50]. Besides, it is worth pointing out that [19] obtained remarkable performances on the clustering task due to its contrastive learning objective aligning with the evaluation metrics.

3) Ablation studies (proposed w/o conv and w/o dl): When the CAMHSA is replaced by the MHSA (*proposed w/o conv*), we noticed a decline in both segmentation and clustering performances. This suggests that the correlations among the attention maps of different heads could potentially play a role in MSA. As for the ablation on the loss functions (*proposed w/o dl*), we found that employing the DL positively impacted the overall performance.

TABLE II: Performance on the clustering task. Note that the L-measure can be applied to the SALAMI dataset only, and it computes a unified score over the two levels although we report the results at the *upper* level.

Level	Model	Pairwise Agreement			L-measure

(b) Evaluation on the SALAMI dataset.

4) Feature Selection Issue (baseline-{m, c, t}): When comparing the baselines, it becomes clear that there is no prevailing feature for MSA. The mel-spectrogram exhibited superiority in the segmentation task, while the chromagram appeared to be preferable to the clustering task. Besides, the tempogram can also provide structural information to some extent. These results highlight the importance of learning higher-level representations and affinity matrices instead of relying on manually crafted features.

5) Visualization of Attention Maps: To examine the knowledge gained by CAMHSA on MSA, we analyzed the attention maps of the testing data from the SALAMI dataset. There were three primary observations exemplified in Fig. 6: 1) the attention heads display a variety of block patterns; 2) the size of the block patterns tends to be larger at the upper level compared to the lower level; 3) the SSM computed from the learned representation ($\mathbf{M}^{\mathbf{P}_s}$) is similar to the annotated one ($\mathbf{M}^{\mathbf{Y}_s}$). The first observation is in line with previous works suggesting that the attention heads can capture diverse relationships. The second observation reflects the fact that the musical segments tend to have longer duration at the upper

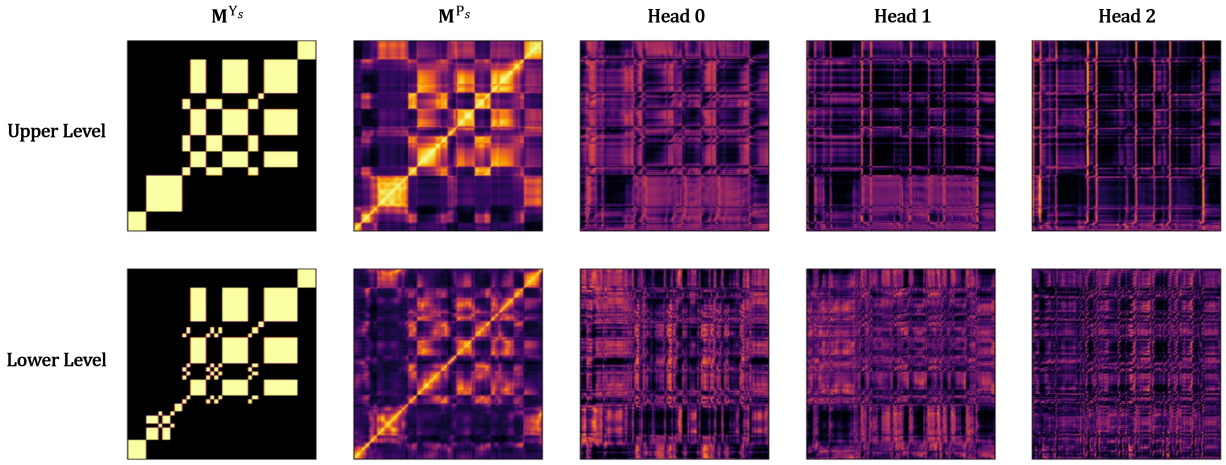

Fig. 6: Visualization of the attention maps for the song "Shim Sham" by Caravan of Thieves (song id 1038 of the SALAMI dataset). $\mathbf{M}^{\{\mathbf{Y}_s,\ \mathbf{P}_s\}}$ is the SSM computed with $\{\mathbf{Y}_s,\ \mathbf{P}_s\}$, respectively. Only the first three heads (index $\{0,\ 1,\ 2\}$) at the second layer of the transformer encoder are shown.

level. The third observation shows that the CAMHSA can effectively combine attention maps from different sources to create a cohesive representation ($\mathbf{P}_s$) that closely resembles the ground truth ($\mathbf{Y}_s$) in terms of SMMs.

V. Conclusion

This research focused on utilizing the multi-head self-attention (MHSA) mechanism to learn a multifaceted view of self-similarity across multiple abstraction levels. To achieve this, we have developed the convolution-augmented MHSA (CAMHSA) mechanism, which fuses various perspectives of self-similarity to extract latent features for audio-based MSA. Through our experiments, we have clearly demonstrated the effectiveness of the CAMHSA by comparing it with other methods that rely on hand-crafted affinity matrices. Especially for the segmentation task, we obtained new state-of-the-art results on the Beatles-TUT and the SALAMI datasets. For the clustering task, we adopted a two-stage framework, where the learning of audio representations is detached from the successive clustering stage. The clustering performance would thus heavily depend on the capability of the employed clustering algorithm. To mitigate this potential incompatibility, we plan to involve a deep clustering method in the current framework. Finally, by fusing different acoustic features, we are able to find a unified structure for each input signal. Examining the differences between the attention maps and SSMs derived from these features can provide musical insights into the relationship between the unified structure and each specific feature.

***Abstract*—We introduce a general framework for measuring acoustic properties such as liner time-invariant (LTI) response, signal-dependent time-invariant (SDTI) component, and random and time-varying (RTV) component simultaneously using structured periodic test signals. The framework also enables music pieces and other sound materials as test signals by "safeguarding" them by adding slight deterministic "noise." Measurement using swept-sin, MLS (Maxim Length Sequence), and their variants are special cases of the proposed framework. We implemented interactive and real-time measuring tools based on this framework and made them open-source. Furthermore, we applied this framework to assess pitch extractors objectively.**

I. Introduction

Computing devices today are 10^9 times more powerful than those available a half-century ago [1]. This power makes it possible to process huge amount of speech materials (for example: [2], [3]). This advancement motivated us to establish a framework for making speech materials more usable based on our recent findings [4]–[6].

The speech materials mentioned above do not necessarily fulfill recommended conditions for scientific research [7]. However, the abovementioned conditions are too strict depending on the research purpose. There is room to make speech materials usable by providing tools for assisting data acquisition and retrospective assesment [8].

The framework we introduce in this article provides a solid basis for tools making speech materials reusable. We start with a big picture of the framework, followed by descriptions of constituent algorithms. Then, we introduce acoustic measurement tools followed by applications other than acoustic measurement. Finally, we discuss issues and related works.

The main contribution of this paper is the fundamental reformulation of the underlying algorithms and the complete revision of the infrastructure, computationally efficient implementation based on FFT and inverse FFT. Our previous works consisted of many conceptual confusions and ad hoc and inefficient procedures [4]–[6], [17], [18], [20]–[22]. This paper enables us to renew all applications and tools while maintaining their functionality.

II. Measurement of acoustic attributes

Figure 1 shows a schematic representation of the whole types of acoustic attributes measurement that we will introduce in this article. The following three subsections outline this framework followed by sections describing technical details and applications.

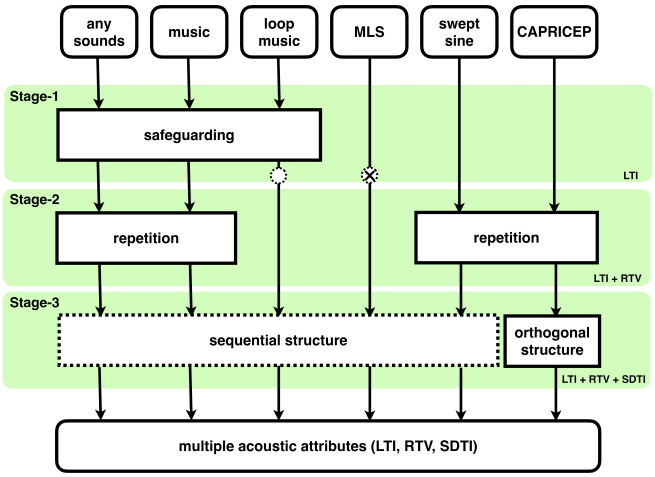

Fig. 1. Acoustic attributes and test signals. (LTI: Linear Time-Invariant, RTV: Random and Time-Varying, and SDTI: Signal Dependent Time-Invariant). The terminal symbol placed at the bottom of Stage-1 on the line from "MLS" represents that results are erroneous. The terminal symbol on the line from "loop music" represents that it destroys the signal design, looping.

A. Linear time-invariant (LTI) response: Stage-1

For linear time invariant (LTI) systems, response to input impulse (impulse response) uniquely determines the target system. In the frequency domain, dividing the Fourier transform of the target system output by the Fourier transform of the input signal provides the transfer function of the target system. The symbol "swept sine" [9] and "MLS" (Maximum Length Sequence [10], [11]) are commonly used test signals. They are members of TSP (Time Stretched Pulse) and have flat power spectrum. The symbol "CAPRICEP" (Casceded All-Pass filters with RandomIzed CEnter frequencies and Phase polority) is also a new member of TSP we proposed [5].

Spectral division using any other signals also provides the transfer function, in principle. However, their spectrum generally consists of very weak component(s) that makes

979-8-3503-0067-3/23/$31.00 ©2023 IEEE

spectral division impractical. We introduced "safeguarding" method for making such signal usable for transfer function measurement [6].

B. Random and time-varying component: Stage-2

Two neighboring periods excerpted from the repeatedly concatenated periodic segments are identical. However, periods excerpted from different parts of the acquired signal are not identical because the background noise and sensitivity fluctuations do not have the same periodicity. The difference between observed periods provides background noise and sensitivity fluctuations information. This way, the repetitive presentation of periodic segments makes simultaneous measurement of the LTI response and the disturbance in the measurement.

C. Signal dependent component: Stage-3

Estimated impulse responses using different input signals are identical when the system is strictly LTI. However, estimated impulse responses of an acoustic system in the real world are not identical for different input signals because of non-linearity, even after suppressing the random and time-varying component by averaging many repetitive measurement results. The differences in estimated impulse responses are the second type of disturbing component. The component depends on the used test signals. It is necessary to describe the used test signals.

Repetition (used in Stage-2) is one type of structuring for the test signal. Sequentially aligning different repetitive test signals is the second type of test signal structuring. Using CAPRICEP, we introduce the third type of structuring, simultaneous structuring, by using the orthogonal nature of the Walsh-Hadamard matrix.

III. Algorithm

This section describes the underlying algorithms in each stage. The test and the acquired signals are discrete-time signals and share the same sampling clock. (In the appendix, we introduce a solution for handling signals sampled by independent clocks.)

A. LTI response: Stage-1, linear convolution

Let $x[n], y[n]$, and $h[n]$ represent an input signal, an output signal, and the impulse response of a system. The time index n is an integer. Assume that $x[n]$ is non-zero for $0 \leq n \leq N-1$ and $h[n]$ is non-zero for $0 \leq n \leq M-1$. Then, the output signal $y[n]$ is non-zero for $0 \leq n \leq M+N-1$. This setting, usually called as "zero-padding", is a common practice to calculate linear convolution using DFT-based circular convolution [12]. (See Fig. 2)

By using the discrete Fourier transform $\mathcal{F}[\cdot]$ of length $L > M+N-1$, the following equation provides the transfer function $H[k]$ of the system. The symbol k represents the index of the discrete frequency.

$$H[k] = \frac{\mathcal{F}[y[n]]}{\mathcal{F}[x[n]]}. \tag{1}$$

Without additive noise, the inverse transform $\mathcal{F}^{-1}[\cdot]$ of the transfer function provides the estimate of the impulse response $h_{\text{est}}[n]$.

$$h_{\text{est}}[n] = \mathcal{F}^{-1}[H[k]]. \tag{2}$$

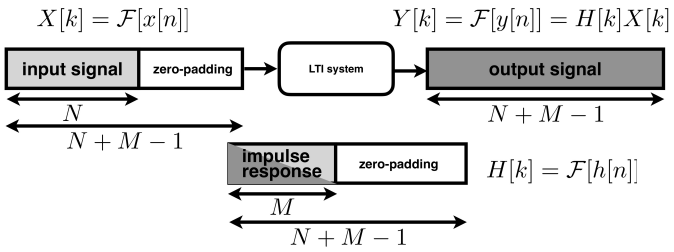

Fig. 2. Convolution of discrete-time signals. Implementation using cyclic convolution with zero-padding.

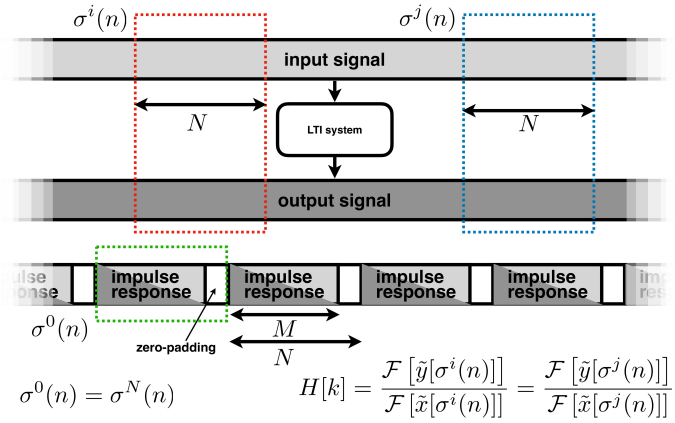

Fig. 3. Convolution of periodic signals. Implementation using cyclic convolution without zero-padding for input and output signals. The same cyclic permutation to input and output does not change the estimated transfer function.

The typical TSP (Time Stretched-Pulse) signal, swept-sine, and the recent member of TSP, unit-CAPRICEP, (usually) have frequency independent gain, such as $|H[k]| = 1$ for all k. Because of the background noise, frequency-dependent gain improves estimation accuracy [13].

1) Terminal symbols: Figure 1 has two terminal symbols for "loop music" and "MLS" at the bottom of Stage-1. We placed the symbol because MLS is a periodic sequence and is orthogonal only under cyclic convolution. The separated single cycle of the MLS sequence is not a time-stretched pulse under linear convolution. For loop music, isolating one repeated phrase is usable for calculating the LTI response, although it is not looping and destroys the original design purpose.

2) Signal safeguarding: Equation (2) holds for input signals with frequency-dependent spectral values. However, the estimated transfer functions are not usable because small absolute values in the denominator magnify the effects of observation noise. Signal-safeguarding, our proposal, significantly suppresses observation noise effects and makes any sounds appropriate for acoustic measurement [6]. With safeguarding, if necessary, all signals are relevant for acoustic measurement.

B. LTI response, and random and time-varying component: Stage-2, cyclic convolution

Figure 3 summarizes this stage. Zero padding is inefficient. The periodic nature of the discrete Fourier transform removes the zero-padding for input and output in Fig. 2.

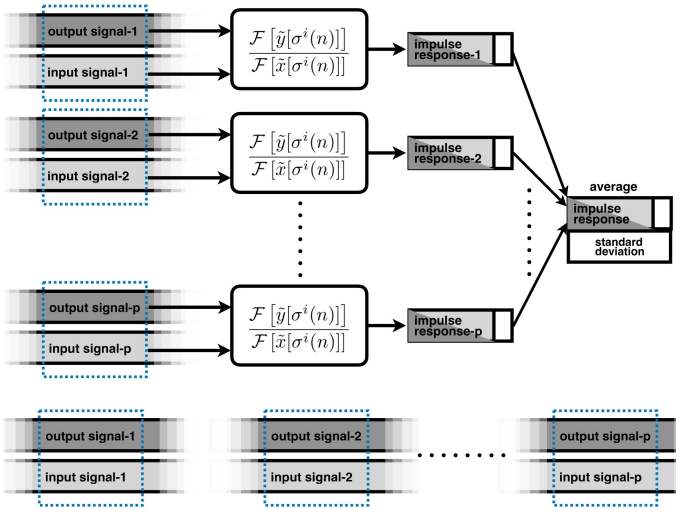

Fig. 4. Serial structuring illustration. Signal-dependent component isolation by averaging and calculating sample standard deviation of estimated impulse responses using different test signals.

Assume that $x[n], y[n]$, and $h[n]$ are periodic and share the same period, L. Then, there is no need for excessive zero-padding for test signals. Using a swept-sine signal in this repetitive presentation, removing zero-valued parts does not cause any problems. The following equation provides the transfer function.

$$H[k] = \frac{\mathcal{F}\left[\tilde{y}[n]\right]}{\mathcal{F}\left[\tilde{x}[n]\right]}, \tag{3}$$

where $\tilde{x}[n]$ and $\tilde{y}[n]$ represent that the signals are periodic.

Periodic test signal enables repeated measurement. Disturbance in measurement, such as background noise and interfering sounds, does not share the same periodicity with the test signal. Then, it is safe to assume that disturbing sounds are independent at each repetition. Averaging of the estimated impulse responses reduces the estimation variance. This averaging and calculation of observed standard deviation provide an estimate of the random and time-varying component (RTV in Fig. 1).

Periodic test signal has additional merits. Because it is periodic, there is no need to repeat the calculation of the Fourier transform of the test signal. Because it is periodic, there is no need to find the initial position of the analysis segment. Wherever the initial position is, the signal is periodic as far as the length is identical to the period. In short, the following holds.

$$\frac{\mathcal{F}\left[\tilde{y}[\sigma^i(n)]\right]}{\mathcal{F}\left[\tilde{x}[\sigma^i(n)]\right]} = \frac{\mathcal{F}\left[\tilde{y}[\sigma^j(n)]\right]}{\mathcal{F}\left[\tilde{x}[\sigma^j(n)]\right]}, \tag{4}$$

where $\sigma^i(n)$ and $\sigma^j(n)$ represent i-th and j-th cyclic permutations of the discrete time sequence n. Figure 3 illustrates these merits.

C. LTI response, and random and time-varying, and signal dependent components: Stage-3, using different test signals

The estimated impulse response is identical when the system is LTI strictly, and no noise exists. However, in actual acoustic measurement, impulse responses estimated using different input test signals are different. Averaging impulse responses using many different test signals provides less distorted LTI response. The difference between each impulse response and the averaged one provides an estimate of the magnitude of signal-dependent deviation. Note that we assume each estimated impulse response for a test signal is an average of repetition, and this averaging suppresses random variations.

Figure 4 illustrates one implementation of this strategy, serial structuring. This serial structuring is the only option for test signals other than CAPRICEP.

D. LTI response, and random and time-varying, and signal dependent components: Stage-3, structured test signal

CAPRICEP has another option, orthogonal structuring. Each unit-CAPRICEP has a raised-cosine-shaped power envelope. Periodic allocation of each unit-CAPRICEP with 50% overlap yields a constant power envelope. We use the Walsh-Hadamard matrix B of order 4 to determine the polarity of three different unit-CAPRICEPs.

$$B = \begin{bmatrix} 1 & 1 & 1 & 1 \\ 1 & -1 & 1 & -1 \\ 1 & 1 & -1 & -1 \\ 1 & -1 & -1 & 1 \end{bmatrix} = \begin{bmatrix} b_{1,1} & \cdots & \cdots & b_{1,4} \\ \vdots & b_{2,2} & & \vdots \\ \vdots & & \ddots & \vdots \\ b_{4,1} & \cdots & \cdots & b_{4,4} \end{bmatrix}. \tag{5}$$

1) Periodic signal generation: The following part describes a procedure to make a periodic test signal $\tilde{s}[n]$ from three different unit-CAPRICEPs. The discrete Fourier transform of $\tilde{s}[n]$ yields discrete spectral representation $S[k]$. The following procedure makes the absolute value $|S[k]|$ a constant, that is independent of the discrete frequency k.

Multiplying coefficient $b_{i,j}$ to each unit-CAPRICEP $g_{\mathrm{uC}}^{(q)}[n]$ and applying the overlap-and-add operation with $N/4$ shift for three different unit-CAPRICEPs provide a base unit sequence $u[n]$.

$$u[n] = \sum_{q=1}^{3} C_q \sum_{r=1}^{4} b_{q,r}\; g_{\mathrm{uC}}^{(q)}\left[n - \frac{(q-1)N}{4}\right] \tag{6}$$

where the super-script q of $g_{\mathrm{uC}}^{(q)}[n]$ is the identifier of each unit-CAPRICEP. The coefficient C_q value is 1 for $q = 1, 2$, and $\sqrt{2}$ for $q = 3$.

The next step is to make a periodic test signal $\tilde{s}[n]$ from the base unit sequence $u[n]$. Since the width of a unit-CAPRICEP is four to six times wider than the allocation interval $N/4$ (see Appendix), it is necessary to allocate (overlap-and-add) $u[n]$ more than $6 + 1$ times to make a periodic segment. Let P represent the number of repetitions. Considering the condition and for simplicity, we select an even number $P \geq 8$.

The periodic test signal $\tilde{s}[n]$ is an excerpt from the following intermediate signal $s_{\mathrm{tmp}}[n]$.

$$s_{\mathrm{tmp}}[n] = \sum_{p=1}^{P} u[n - (p-1)N], \tag{7}$$

Excerpting a segment with length N around the center location of $s_{\mathrm{tmp}}[n]$ provides the periodic test signal $\tilde{s}[n]$.

$$\tilde{s}[n] = s_{\mathrm{tmp}}\left[n - \left(\frac{P}{2} - 1\right) N\right], \quad (n = 0, \ldots, N-1) \tag{8}$$

2) Simultaneous multiple impulse response measurement: The following procedure provides three different impulse responses from the output signal $\tilde{y}[n]$. First, similar to the second stage, using the ratio of the discrete Fourier transform of input test signal and output provides an estimate of the impulse response $\hat{h}_{\mathrm{L}}[n]$.

$$\hat{h}_{\mathrm{L}}[n] = \mathcal{F}^{-1}\left[\frac{\mathcal{F}[\tilde{y}[n]]}{\mathcal{F}[\tilde{s}[n]]}\right], \tag{9}$$

where the subscript L of $\hat{h}_{\mathrm{L}}[n]$ represents that it is a longer impulse response obtained from the measurement. The length of $\hat{h}_{\mathrm{L}}[n]$ is L. Although, in actual measurement, other than the initial part, the noise floor (due to background noise and non-linearity, mainly) masks the impulse response corresponds to the LTI part.

The orthogonal structure of $\tilde{s}[n]$ provides three shorter impulse responses by using the virtual target signal $\tilde{v}_{\mathrm{S}}^{(q)}[n]$.

$$\tilde{v}_{\mathrm{S}}^{(q)}[n] = \sum_{r=1}^{4} b_{q,r}\ \delta\left[n, \frac{(q-1)N}{4}\right], \tag{10}$$

where $\delta[i, j]$ is the Kronecker delta and q identifies the corresponding unit-CAPRICEP.

The first $N/4$ elements of the signal defined by the following equation provide a short impulse response $\hat{h}_{\mathrm{S}}^{(q)}[n]$.

$$\hat{h}_{\mathrm{S}}^{(q)}[n] = \mathcal{F}^{-1}\left[\frac{\mathcal{F}[\tilde{v}_{\mathrm{S}}^{(q)}[n]]\mathcal{F}[\tilde{y}[n]]}{\mathcal{F}[\tilde{s}[n]]}\right]. \tag{11}$$

As noted, the initial $N/4$ elements are unique and relevant for impulse response estimates. Deviations from the same initial part of $\hat{h}_{\mathrm{L}}[n]$ represent the signal-dependent component.

Note that $\mathcal{F}[\tilde{v}_{\mathrm{S}}^{(q)}[n]]$ functions as a selector of discrete frequency components. Figure 5 illustrates how it works in the discrete frequency domain. For example, $\hat{h}_{\mathrm{S}}^{(1)}[n]$ selects the bleu-colored component, and $\hat{h}_{\mathrm{S}}^{(2)}[n]$ and $\hat{h}_{\mathrm{S}}^{(3)}[n]$ select red-colored and yellow-colored components.

There is a caveat that the procedure above suppresses the signal-dependent component resulting from even-symmetric nonlinearity. It is necessary to estimate impulse responses using the negated test signal $-\tilde{s}[n]$ to detect components caused by even-symmetric nonlinearity.

E. Implementation details

The descriptions mentioned above are simplified summaries. We placed descriptions of technical details in Appendix sections for readability. The discussed details are as follows: a) Optimized weighting shape for reducing artifacts due to truncation of acquired interfering signals. (Appendix A) b) Phase manipulation function that makes better localization of the generated unit-CAPRICEP. (Appndix B) c) Evaluation of signal safeguarding merits. (Appendix C)

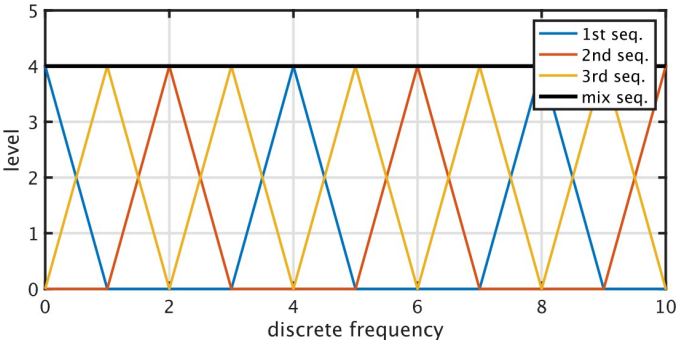

Fig. 5. Discrete spectral levels of the whole test signal $\tilde{s}[n]$ and constituent sequences corresponding first, second, and the third unit-CAPRICEP. The plot shows the initial 11 discrete frequency components.

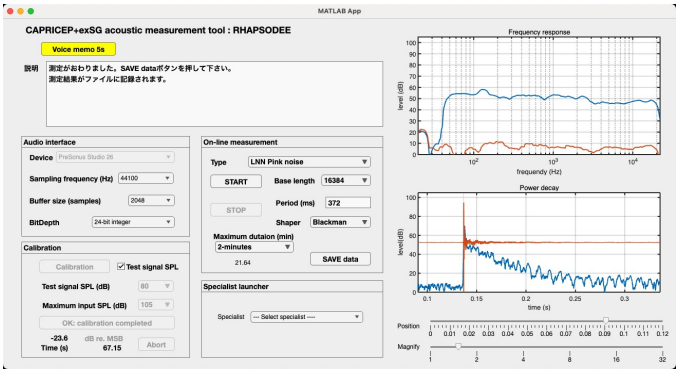

Fig. 6. Snapshot of the GUI of the "Control panel" for acoustic calibration and application launcher [15].

IV. Acoustic Measurement Tools

We developed acoustic measurement tools based on the proposed framework. This section introduces several examples. The tools introduced here are accessible in the first author's GitHub repositories [14].

A. Control panel for acoustic applications

Figure 6 shows a snapshot of the GUI of the "Control panel" for acoustic calibration and application launcher [15]. The top-left wide field is for showing prompt instructions for users. The left-middle and bottom sub-panels are for setting the audio interface and calibrating input sensitivity. The center sub-panel is for controlling the acoustic measurement. The center-bottom sub-panel is the application launcher.

Figure 7 shows a collection of GUI snapshots of speech-related applications we developed [15]–[18]. Selecting an item from the dropdown menu in the application launcher sub-panel launches the application.

The screenshot of Fig. 6 shows an interactive and real-time measurement of the sound recording environment using a periodic test signal with a modified pink-noise spectral shape. A powered loudspeaker (IKmultimedia iLound Micro Monitor) simulates a talker, and a measuring microphone (Earthworks M50) placed 20 cm in front of the loudspeaker acquires the output sound. The top-right graph shows the smoothed gain (blue line) of the transfer function $H[k]$ and the smoothed

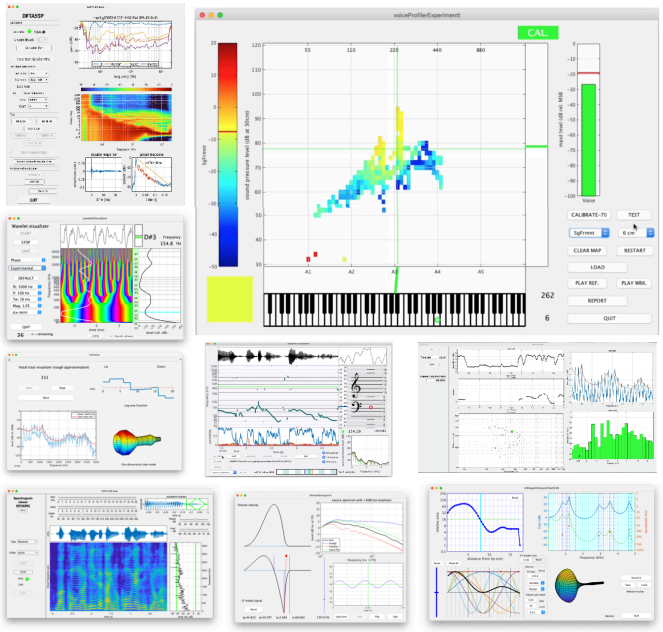

Fig. 7. Snapshots of application GUIs [15]–[18]. This controller launches applications by selecting the dropdown menu in the application launcher sub-panel.

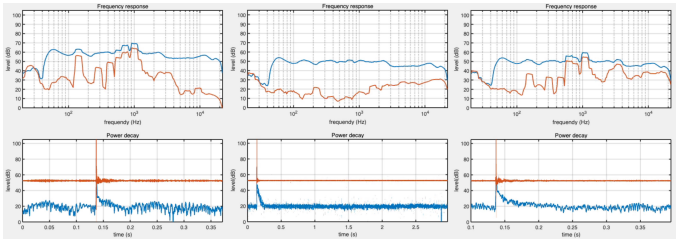

Fig. 8. Snapshots of monitored acoustic conditions. The left shows when the experimenter disturbed the measurement by one's voice /a/. The center shows the monitored LTI response and background noise using a test sound that is a safeguarded utterance (a Japanese sentence /bakuoN ga ginsekai no kougen ni hirogaru/ "A roaring sound spreads across the silvery snow-covered plateau.") spoken by a Japanese male. These are snapshots excerpted from a demonstration movie.

disturbing component (red line). The following graph shows the impulse response waveform (red line) and the smoothed power of the impulse response represented in dB (blue line).

Figure 8 shows monitored results in different conditions. These snapshots are excerpts from a demonstration movie[1].

The left graph shows when the experimenter disturbs the measurement by producing a loud /a/ voice. The disturbing component in the red line pushes the LTI estimate at several parts. The smoothed impulse response power also shows distortions in low-level parts.

The center graph shows the result using a safeguarded read sentence. The length of the period of the test signal used in this measurement is 2^{17}. Figure 16 in Appendix C shows the spectra of the original and safeguarded signals. The measured LTI gain is virtually identical to the result in Fig. 6. However, the level of disturbing components is higher than Fig. 6. It is because the power spectral level in the higher frequency region of the safeguarded test signal decreases steeper than that of the pink noise. Note that the noise floor, due to background noise, masks the smoothed power level of the estimated impulse response other than the initial part of the impulse response.

The right graph shows when the experimenter disturbs the measurement by producing a loud /a/ voice, similar to the left graph. Similarly, the disturbing component in the red line pushes the LTI estimate at several parts. There are differences in the shape of the disturbing components in the left and right graphs. The disturbing level is lower in the low-frequency region and higher in the high-frequency region. These differences are due to the spectral difference of the test signals. The pink noise-shaped test signal has higher energy in the high-frequency region than the safeguarded speech sounds.

V. Other Applications

We developed several tools other than acoustic measurement based on the proposed framework. This section introduces two applications closely related to each other.

The first one is measurement of voice f_o (fundamental frequency[2] This research measures the frequency modulation transfer function using the f_o frequency modulation by the spectrally shaped test signal made from CAPRICEP as the test signal. Then the f_o modulation of the produced voice sound as the output.

The second one is an objective measurement of pitch extractors using the f_o modulation transfer function [22]. In this investigation, we replaced the human with the pitch extractor. The movie that compares 16 pitch extractors using this method is informative[3].

VI. Discussion and Related Works

The proposed framework does not replace existing acoustic measurement methods. Instead, it provides them additional values and is an efficient computational infrastructure. For example, exponential swept-sine analyzes nonlinearity in a diagnostic way [24]. Our proposed framework provides information on the target system's behavior handling signals they are designed to use. In this manner, the proposed framework plays a complementing role in acoustic measurement.

Reverberation radius [23] represents the distance where the energy of the direct and the reverberant sounds equals. It is an essential attribute in, for example, classroom acoustics. Our method enables us to measure the reverberation radius and other acoustic attributes using actual teaching materials in a classroom while teaching students. Moreover, using the smartphones of each student, simultaneous measurements of each student's listening acoustic conditions are possible.

VII. Conclusions

We introduced a general framework for measuring acoustic properties such as liner time-invariant (LTI) response, signal-dependent component, and random and time-varying component simultaneously using structured periodic test signals. The framework also enables music pieces and other sound materials

[1] https://youtu.be/-nxD-8hbCv4

[2] See [19] for the reason why we are using f_o instead of using F0) response to auditory stimulation [20], [21].

[3] https://youtu.be/iXnP1tIuVic

as test signals by "safeguarding" them by adding slight deterministic "noise." Measurement using swept-sin, MLS (Maximum Length Sequence), and their variants are special cases of the proposed framework. We implemented interactive and real-time measuring tools based on this framework and made them open-source. Furthermore, we applied this framework to assess pitch extractors objectively. The proposed framework is general enough and applicable to many other fields.

APPENDIX

A. Reducing truncation artifacts

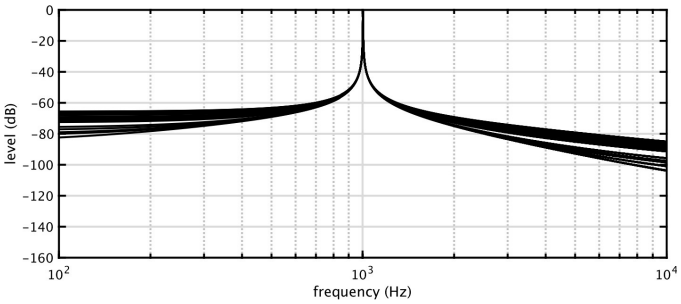

Fig. 9. Power spectra of truncated signal without any shaping the both ends.

Figure 9 shows an example of signal truncation asynchronous to the signal. This example uses a sinusoid having

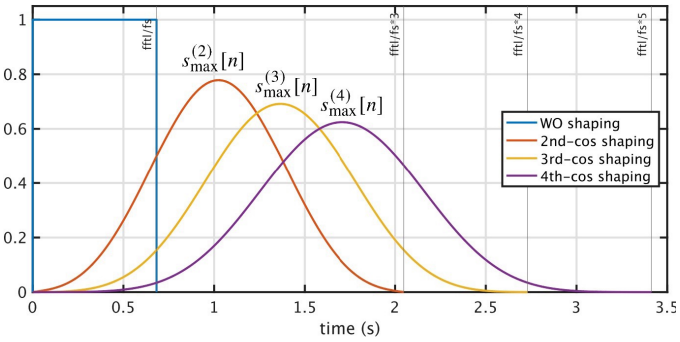

Fig. 10. Periodicity preservation tests of shaping functions. Plot shows the weighting function shapes.

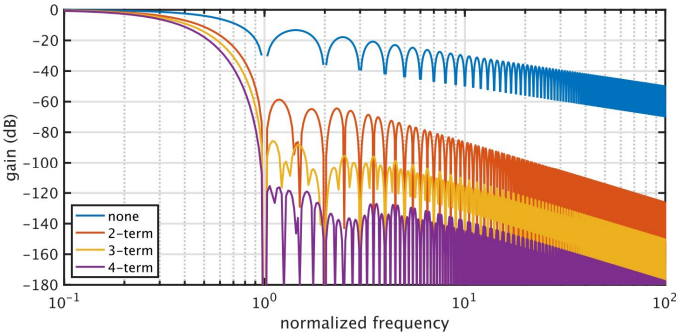

Fig. 11. Optimized weighting functions made from several cosine series convolved with a rectangular function with the repetition period length. They are numerically optimezed to minimize the maximum side-lobe level.

a frequency $1000 + \pi$ Hz. As shown in the figure, truncation produces spectral spread.

Using more than one cycle of the periodic signal and a weighting function reduces this issue. The weighting function has to be a constant value one when wrapped. Figure 10 shows such weighting functions. They are cosine-based window functions convolved with a rectangular function having the period width. The annotation $s^{(k)}_{\max}[n]$ indicates that the convolved cosine series has k-terms. The coefficients are numerically optimized to minimize the maximum side-lobe level.

Figure 11 shows their frequency responses.

Figure 12 shows the same asynchronous signal truncated using the optimized weighting function $s^{(4)}_{\max}[n]$. Note that

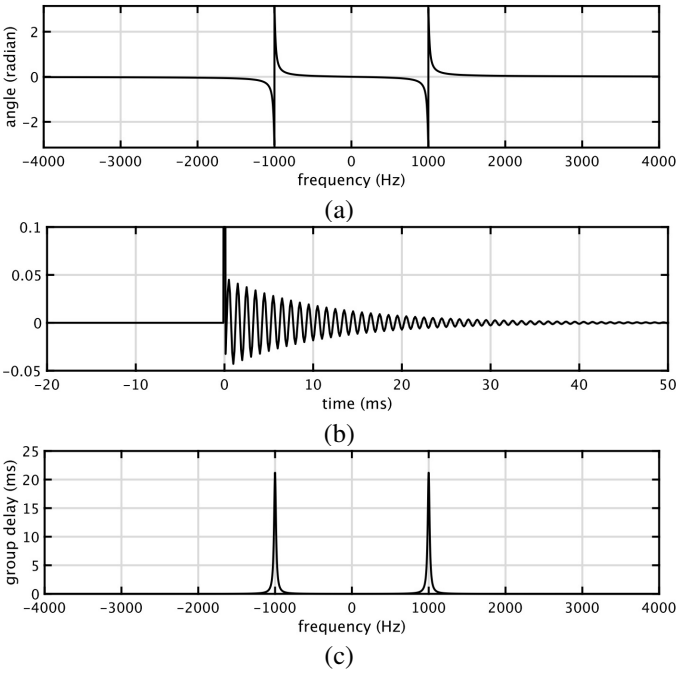

Fig. 14. Attributes of IIR-type all-pass filter. (a) phase-frequency response, (b) impulse response, and (c) group delay response.

weighting effectively suppressed the spectral spreads.

B. *Phase manipulation function*

Let us start with the result. Figure 13 shows the RMS average of the unit-CAPRICEP designed using a phase manipulation function of the original proposal [5] (IIR) and the error function, integrated Gaussian function (Erf) and its approximating function sigmoid (sigmoid).

Figure 14 shows an example of relations between phase manipulation, impulse response, and the group delay of the initially proposed phase function [5]. It is the phase of an IIR all-pass filter. This manipulation example and the following examples use phase manipulation at one point, 1000 Hz. The actual unit-CAPRICEP of 0.25 s effective width consists of about 7000 phase manipulation points.

Figure 15 shows impulse responses using the error function

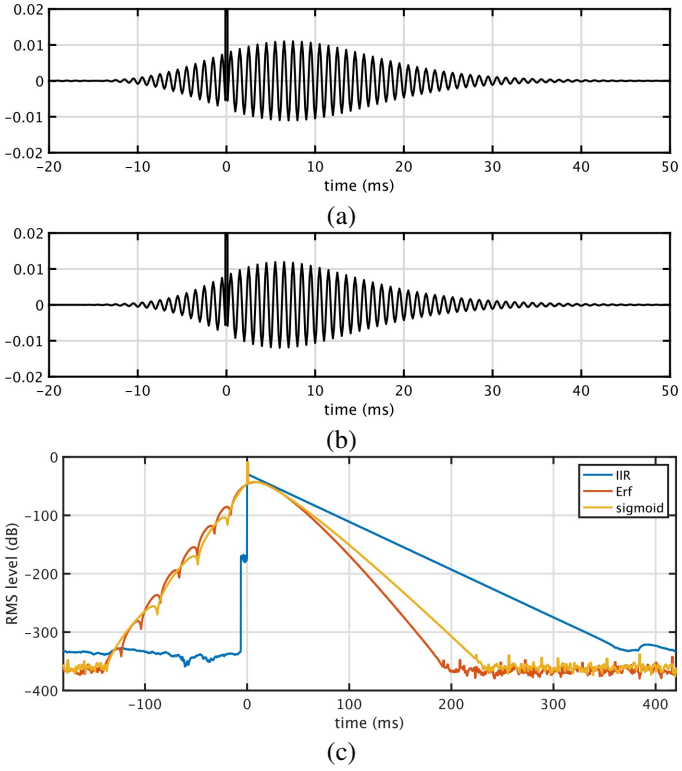

Fig. 15. Impulse response of the all-pass filters made from error function (a) and the sigmoid (b). The plot (c) shows smoothed RMS levels (in dB) of the impulse response of the IIR (original CAPRICEP [5]), the error function (Erf), and the sigmoid (sigmoid).

and the sigmoid. The bottom plot compares IIR, Erf, and Sigmoid's power decay. The decay of Erf is the steepest, and we selected Erf to design unit-CAPRICEP in our implementation.

C. Safeguarded signal and its merits

This is a revised excerpt form [6]. Let $x[n]$ be a periodic discrete-time signal with a period L. Convolution of $x[n]$ and the impulse response $h[n]$ of the target system yields the output $y[n]$. Because the signal is periodic, the DFT (Discrete Fourier transform) of $x[n]$ and $y[n]$ segments (their length is L) are invariant other than the phase rotation proportional to frequency. Let $X[k]$ and $Y[k]$ represent their DFT, where k, $(k = 0, \ldots, L-1)$, is the discrete frequency. Then, the ratio $Y[k]/X[k]$ is independent of the location of the segment. This ratio agrees with the DFT $H[k]$ of the impulse response $h[n]$, where $X[k] \neq 0$ for all k values is the condition of this relation to provide physically meaningful results.

However, this simple solution is sensitive to noise when the absolute value $|X[k]|$ is very small relative to absolute values $|H[k]|$ of other k values. We propose to limit the absolute value $|X[k]|$ to have larger value than a threshold[4]. We use the following equation to derive the DFT $X_s[m]$ of the safeguarded signal $\tilde{x}_s[n]$.

$$X_s[k] = \begin{cases} \dfrac{\theta_L[k]X[k]}{|X[k]|} & \text{for} \quad 0 < |X[k]| < \theta_L[k] \\ X[k] & \theta_L \leq |X[k]| \end{cases}, \qquad (12)$$

where we set $X_s[k] = \theta_L[k]$ when $X[k] = 0$. Then, we derive the safeguarded transfer function $H_s[k]$ as follows.

$$H_s[k] = \frac{Y_s[k]}{X_s[k]}, \qquad (13)$$

where $Y_s[k]$ represents the DFT of the output of the target system for periodic test signal $\tilde{x}_s[n]$. Because the safeguarded signal $\tilde{x}_s[n]$ is periodic, we can make *the safeguarded test signal* for acoustic measurement by concatenating it as many times as required.

Figure 16 shows example of safeguarding. The level represents the absolute values of discrete Fourier transform of a whole sentence length samples (the original and safeguarded ones). Figure 17 illustrates the merit of safeguarding.

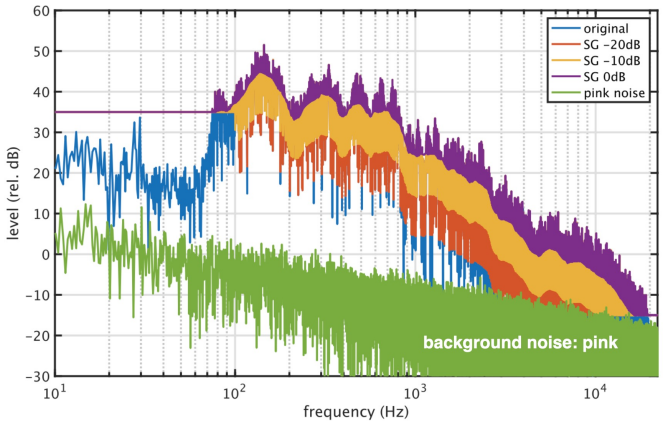

Fig. 16. Absolute values of the original (a Japanese sentence /bakuon ga ginsekai no kougeN ni hirogaru/ spoken by a male speaker) and safeguarded speech samples. The signal period is 2^{17} samples at 44100 Hz. Frequency-dependent thresholding uses a smoothed power spectrum with 1/3 octave width as a reference. The light green line represents the background pink noise for testing noise tolerance.

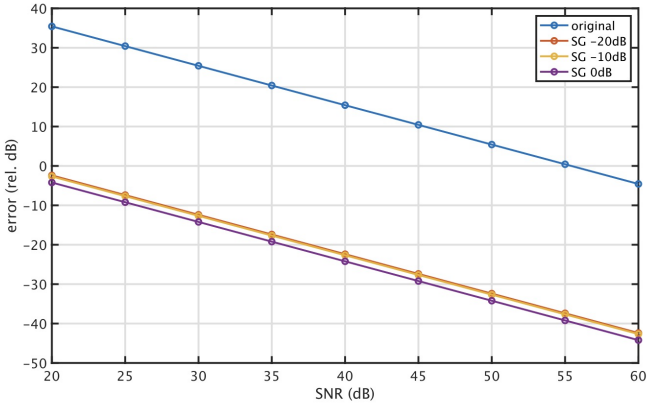

Fig. 17. Estimation error of the impulse responses using the original and the safeguarded signals for the test signal. For noise tolerance test, we added a background pink noise as shown in Fig. 16.

[4]In actual implementation we use frequency dependent threshold $\theta_L[k]$ using power spectra of the original signal and the background noise. We also set the minimum level and low frequency limit for $\theta_L[k]$.

Cognitive Assessment of Autism Spectrum Disorder Using an EEG-based Social Interaction Platform

Abstract — **Previous studies have suggested a strong correlation between social interaction skills and the social environment, as well as personal experiences. Neuroimaging studies have further demonstrated the link between social interaction and brain oscillations. In this study, we developed a game-based social training platform that recorded electroencephalography (EEG) signals to provide neurophysiological indicators for cognitive assessment in autistic teenagers. Both typically developed (TD) participants and individuals with autism spectrum disorder (ASD) were recruited to participate in the social training game, with 12-channel EEG signals recorded during the sessions. The EEG signals underwent preprocessing, and the event-related potentials (ERPs) and event-related spectral perturbations (ERSPs) were analyzed and compared between the two groups. Six machine learning frameworks were employed for computer-aided assessment of ASD. The results revealed that the support-vector machine with a polynomial kernel function achieved the highest balanced accuracy of 91.67% when both ERPs and ERSPs were utilized as features for evaluating autism. These findings suggest the potential use of EEG features incorporated into a game-based social training interface for the cognitive assessment of ASD.**

I. Introduction

Autism spectrum disorder (ASD) is a neurodevelopmental disorder classified in the Diagnostic and Statistical Manual of Mental Disorders Fifth Ed. (DSM-5) [1]. Previous research suggests that individuals with ASD often struggle with facial processing and recognizing emotions, which impacts their ability to express emotions and affects their social cognition [2, 3]. Recent studies propose that challenges in social interaction among individuals with ASD can be attributed to impaired social motivation and deficits in basic perception [3-5]. Early interventions and cognitive assessments based on developmental and neuroimaging findings are essential for effectively evaluating the social and cognitive abilities of individuals with autism.

The use of game-based training platforms for behavioral interventions has gained popularity due to the reported enjoyment of individuals with autism in using computer technology [6]. In the preceding decade, a multitude of serious games have been created with the purpose of delivering individualized training and conducting cognitive assessment within domains encompassing emotions, social interactions, and communication [7-10]. These games cover various aspects of training, including behavioral, affective, cognitive functions, and social skills [10]. However, the effectiveness of these games has primarily been evaluated through behavioral questionnaires or verbal feedback. Progress in human-machine interfaces has opened avenues for integrating physiological indicators like heart rate, electroencephalography (EEG), and eye-tracking into forthcoming interfaces based on gaming. Utilizing these physiological signals will enable a deeper understanding of the underlying mechanisms and identification of reliable biomarkers for computer-aided diagnosis, cognitive assessment, and the effectiveness of game interventions.

To address the subjectivity of current behavior-dependent diagnosis and cognitive assessment processes, various neurophysiological and neuroimaging methods have been employed to investigate the relationship between brain functionality and autism behavior [11]. Among these methods, EEG stands out as a valuable tool for investigating and diagnosing ASD [12, 13]. Several studies have successfully detected ASD using EEG [13]. The physiological features extracted from these previous investigations can be broadly categorized into groups, including spectral power [12, 14-16], functional connectivity [17-19], and information dynamics [20].

In this study, we have developed a social cognitive paradigm specifically tailored for autistic teenagers. To evaluate brain oscillations and functional connectivity during the game, we recorded EEG signals using a mobile EEG device. Our

979-8-3503-0067-3/23/$31.00 ©2023 IEEE

previous research [21] has demonstrated that deficits in joint attention and basic gaze perception can hinder the development of social cognition in individuals with ASD. Building upon these findings, our hypothesis for this study was that altered brain oscillations could be observed in autistic preadolescents during social interaction, and these patterns could serve as promising biomarkers for assessing social abilities in autistic preadolescents.

II. Materials and Methods

A. Participants

This study recruited 18 participants, consisting of 12 typically developing (TD) preadolescents (aged 11.83 ± 1.27; seven boys) and 6 autistic preadolescents and adolescents (aged 13.83 ± 3.71; four boys). Participants with a history of head trauma, neurological, and physiological diseases were excluded. All autistic participants were recruited from National Taiwan University Hospital, and diagnosed according to the diagnostic criteria of the DSM-5 [1] and International Classification of Diseases (ICD-10; WHO 1994). Approval for this study was granted by the Research Ethics Committee at National Taiwan University Hospital, Taiwan (REC no. 201709023RIPD). Written informed consent was obtained from all legal guardians of the participants before the commencement of the experiment.

B. Game-based Interface for Social Cognitive Training

A game-based training interface was designed including several interactive scenarios with different topics for autistic preadolescents and teenagers to learn, such as recognition of facial emotional expressions and social interaction skills. This game-based social cognitive interface is divided into events to fit the criteria of designing an EEG experimental paradigm. The Unity game engine (Unity Technologies 2018.1.14f) was used to develop the games and synchronize the timing with a mobile EEG system. As depicted in Fig. 1A, the game-based interface comprises two modules, each operating with distinct modes. The initial module introduces an intricate version of the facial emotional recognition game, encompassing fundamental facial expression techniques and attention-sharing elements. The second module integrates the first one and uses role-playing and first-person scenarios to simulate social interactions close to real life (Fig. 1B). Proper rewards are offered in the game based on the ages and preferences of the participants. The resultant game for social cognitive training is a 30-minute, personalized interactive computer-based activity. It encompasses 84 trials focused on facial emotion recognition and 45 trials centered around selecting social behaviors. These

Fig. 1 The game-based social cognitive paradigm with scenarios for the selection of (A) emotional expressions and (B) appropriate behaviors.

trials are synchronized with the wireless EEG system through triggers conveyed via the lab streaming layer. The game aims to evaluate the abilities of facial emotional recognition and social behavioral reactions. Within each trial, a 12-second scenario description is presented. Subsequently, participants are directed to establish eye contact with a character displayed on the screen and correctly identify the corresponding facial emotional expression aligned with the given social context (taking 1-3 seconds). Lastly, participants are prompted to choose a suitable behavior or reaction in accordance with the character's social interactions (allowing 7-10 seconds). Subsequent analysis focused on the participants' behavioral and electrophysiological responses within these two conditions.

C. EEG Recording and Signal Processing

A mobile and dry-electrode EEG headset (Quick-20 Dry EEG Headset, Cognionics, Inc., San Diego, CA) was used for EEG recording while the participants were playing the social training game. According to the 10–20 system, EEG signals from 12 scalp locations were recorded, including F3, F4, F7, F8, Fz, C3, C4, P3, P4, P7, P8, and Pz, with a reference on A1.

The sampling rate of the EEG signals was 500 Hz, and the signals were then amplified with a band-pass filter with a bandwidth of 0 to 50 Hz. The stimuli triggers were synchronized with EEG data streams and consolidated into a unified file employing the LSL data acquisition and synchronization framework. EEG data were analyzed using MATLAB R2021b (The MathWorks, Inc., Natick, Mass, USA). For the preprocessing of EEG data, independent component analysis and artifact subspace reconstruction from the EEGLAB toolbox [22-24] were used to identify and remove artifact components and trials for each subject. The cleaned and epoched EEG data then underwent Morlet wavelet transformation to retrieve the event-related potentials or oscillations (ERPs or ERSPs). Group-level averaged ERSPs were computed relative to the baseline period for each channel location. The parametric paired t-test was conducted for each time-frequency interval to examine the difference of brain oscillations between the two groups at distinct frequency bands.

D. Computer-aided assessment

The machine learning-based classification process involves feature extraction and classification. To extract representative features, the F score is employed to rank all potential features extracted from ERPs and ERSPs. For the classification task, six different classifiers are employed, namely k-Nearest Neighbors (kNN) with a neighbor number of ten (k = 10), Binary Decision Tree (BDT), Gentle Adaptive Boosting (GAB), Support Vector Machine (SVM) with linear, radial, and polynomial kernel functions. he optimization for classification was resolved using the SVM toolbox function LibSVM [25] incorporated in MATLAB R2021b. The performance of the classification methods was evaluated by leave-one-subject-out validation due to the limited number of participants. Groups of training sets and testing sets were fed into the classifiers. The categorization performance of the proposed framework is measured using sensitivity, specificity, F1 score, and balanced accuracy averaged after 100 iterations.

III. Results and Discussions

A. Rule-based feature extraction

The ERPs were compared between autistic and TD participants in Fig. 2 during facial emotional recognition. The average ERPs in the parietal regions (Pz and P7) were compared. Significant differences were observed around 200-240 ms and 550-750 ms between the two groups. Increased amplitudes of P2 components between 200 and 240 ms after the stimulus onset were observed at P7 in autistic preadolescents and adolescents (Fig. 2A). Fig. 2A presents the

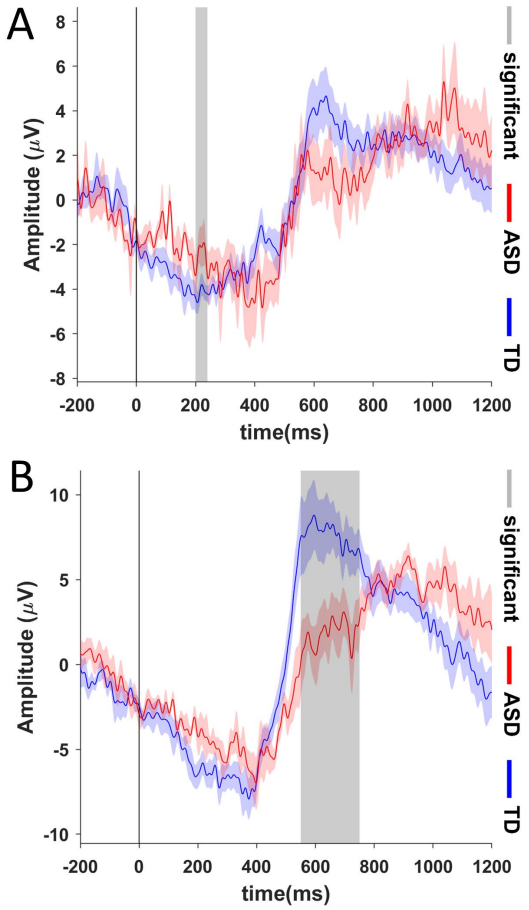

Fig. 2 The average ERPs during facial emotional recognition of the social cognitive game in the following time intervals in the parietal regions: (A) 200-240 ms (P2 component) at P7, and (B) 550-750 ms (LPP component) at Pz.

collective mean amplitudes and grand averages of the P2 waveform at channel P7. When contrasted with the TD group's mean of -4.18 ± 1.53 μV, the ASD preadolescents' mean of -2.44 ± 1.72 μV indicated a relatively augmented P2 ($p = 0.041$). This finding suggests an impairment in the structural encoding of facial features among the ASD group. The grand averages of the LPP waveforms at the Pz channel and the corresponding mean amplitudes are shown in Fig. 2B, which can be considered as a component to capture the allocation of attention toward motivational salient objects [26-31]. The autistic participants exhibited a smaller LPP (1.79 ± 3.58 μV) than the TD group (7.60 ± 4.72 μV, $p = 0.024$). This implies that preadolescents and adolescents with autism encountered challenges in directing attention towards the target stimulus.

The results of ERSPs revealed that brain oscillations in the delta, theta, and beta frequency bands showed significant differences between the two groups during facial emotional

recognition of the social-cognitive game. In TD preadolescents, there was a notable increment of theta (5-8 Hz) synchronization around 400 ms in the left frontal (F7) regions. However, this phenomenon was not observed in autistic participants ($p < 0.001$). In contrast, larger delta (1-4 Hz) synchronization is observed in autistic preadolescents in the left frontal ($p < 0.001$), right central ($p = 0.022$), and right parietal ($p < 0.001$) regions, as well as larger beta desynchronization between 15 and 20 Hz in the left frontal ($p < 0.001$) and right central ($p = 0.006$) regions after 500 ms.

Table 1 Performance for different machine learning classifiers (kNN: k-nearest neighbors; BDT: Binary decision tree; GAB: Gentle adaptive boosting)

Classifier	*Sensitivity(%)*	*Specificity(%)*	*F1 score*	*Balanced accuracy(%)*
kNN	50	100	0.67	75.00
BDT	83	75	0.71	79.17
GAB	67	83	0.67	75.00
SVM-linear	83	92	0.83	87.50
SVM-poly	**83**	**100**	**0.91**	**91.67**
SVM-radial	67	92	0.73	79.17

B. Results of machine learning

Table 1 presents the overall performance of the six classifiers mentioned. Among them, the SVM-based approach with a polynomial kernel function demonstrates the highest overall performance with a balanced accuracy of 91.67%, while the kNN and GBA-based methods show the lowest overall performance with balanced accuracy of 75.00%. In terms of sensitivity, the BDT classifier and SVM framework with linear and polynomial kernel functions achieve the highest value of 83%, and kNN has the lowest sensitivity of 50%. On the other hand, kNN and SVM with a polynomial kernel exhibit the highest average specificity value of 100%, and BDT has the lowest specificity value of 75%. In summary, SVM achieves the highest performance in terms of balanced accuracy and maintains a good balance between sensitivity and specificity, resulting in F1 scores and accuracy values of 0.91.

IV. Conclusions

Rather than relying on behavioral questionnaires, we employed an EEG-compatible social interaction game to assess cognitive abilities. We analyzed the altered ERPs and ERSPs in preadolescents with autism during the game. Our results indicate that these atypical EEG responses can be dependable indicators for assessing emotional recognition, social information processing, and cognitive functions in autistic teenagers. Specifically, we noted modified amplitudes of the P2 and LPP components, along with decreased theta synchronization and beta frequency band desynchronization in individuals with autism. Using SVM, computer-aided assessment of autism achieved a high performance with a balanced accuracy of up to 91.67%. This study highlights the potential of incorporating EEG as an indicator for computer-aided diagnosis and evaluation of cognitive performance during real-life game playing, given its portability and flexibility compared to other neuroimaging techniques.

Abstract* — *This case series cohort study investigated gait characteristics based on sensor data obtained from personalized active powered lower limb exoskeletal robot-assisted gait training and assessed its putative therapeutic effects in patients with stroke. Preliminary findings suggest that the application of the exoskeletal robot did not improve gait symmetry under robot assistance and could facilitate inter-joint coordination within the hip-knee joint movement on the affected side. These findings suggest that robot-assisted gait training could improve gait by guiding motor learning.

I. INTRODUCTION

Cerebrovascular disease, a leading cause of disability worldwide, particularly causes hemiplegia even following a full course of rehabilitation, a condition inducing a partial or complete loss of ambulatory ability and significant healthcare burdens. However, advancements in the field of exoskeletal rehabilitation robots present a promising opportunity for aiding stroke patients in their ambulation training.

Among these developments, the personalized lower limb exoskeletal robot (PLER) offers advantages in the realm of stroke rehabilitation. It provides personalized and highly repetitive training, which fits the unique needs of each patient and compensates for their specific gait. This adaptability sets the PLER apart from conventional rehabilitation methods. However, it is important to acknowledge that the application and setup of the PLER involve a complex and laborious process. The gait control of the robot relies on a variety of parameters, and each patient presents varying degrees of strength, posture, spasticity, and symmetry. Consequently, configuring these parameters during the early fitting phase is challenging and thus demands significant expertise from engineers and clinical professionals. In this sense, a rapid determination of the optimal control parameters within a short timeframe will be pivotal for enhancing usability, patient satisfaction, and overall clinical effectiveness.

It is important to apply appropriate methods for analyzing the gait function when a subject is using a robotic device. Spatiotemporal gait parameters, such as gait velocity[1] and gait symmetry[2, 3], are widely used and are helpful in measuring walking performance. Gait symmetry is a vital complementary measure to gait velocity[3]. Clinically, the reduction of asymmetry is commonly addressed by therapists particularly in the post-stroke population[4]. Gait symmetry can be considered an indicator of the degree of gait control as it is a summary measure of gait parameters between the two lower limbs. Although previous studies have introduced several symmetry indexes for gait analysis, these indexes have certain limitations, such as low sensitivity [2], reliance on a single point or a limited set of points from waveforms to determine symmetry, and failure to analyze the entire curve or gait cycle comprehensively.

The inter-joint coordination can be quantified by a range of techniques that provide differing complexity and accuracy of results [6]. The cyclogram, also called the angle-angle diagram, proposed by Grieve[5], might be used to represent inter-joint coordination, the functional relationship between joint pairs during a whole gait cycle. The cyclogram is formed by plotting two angles directly, such as the alteration of hip and knee joint angles, in an X-Y plane without time information. It is possible that the cyclogram can be used clinically by analyzing geometric properties, such as its range of motion, area, and perimeter, as studies have supported the utility of the cyclogram for orthopedic [7, 8] and neurologic conditions [9, 10].

979-8-3503-0067-3/23/$31.00 ©2023 IEEE

In the present case series cohort study, the strategy of personalized parameter setting of PLER was conducted by asking the patients to perform their best gait symmetry during the robot-assisted walking. We also recorded the gait signal before and during each robot-assisted walking, and then analyzed these signals using cyclogram-based spatiotemporal analysis. Finally, we analyzed the treatment effect by clinical assessment. The specific aims of this work are (1) to investigate the effects of the use of personalized parameter setting with performing a better gait symmetry in robot-assisted training, and (2) to explore indexes for monitoring the change of gait induced by the robot-assisted training.

II. Materials and Methods

A. Participants

The participants with stroke, whose age is ≧ 20 years, and without exclusion criteria of: (1) Individuals who are unable to stand and walk even with the support of lower limb exoskeleton robots; (2) vulnerable populations prone to injuries; (3) non-native speakers; (4) participants with conditions such as aphasia, moderate to severe cognitive impairment (e.g., moderate to severe dementia), or mental disorders (e.g., delirium) that hinder their ability to cooperate with the experiment; (5) individuals with severe musculoskeletal disorders of the lower limbs (e.g., fractures, tendon ruptures) that make them unable to withstand external forces; (6) individuals with skin disorders (e.g., pressure sores, wounds, cellulitis) that prevent them from using lower limb exoskeleton rehabilitation robots; (7) individuals with complete paralysis of the lower limbs or unhealed ulcers; (8) individuals with unilateral or bilateral deep vein thrombosis of the lower limbs or amputations; (9) individuals with severe hypertension who cannot maintain resting blood pressure within 180/100 millimeters of mercury (mmHg) under medical control; (10) Individuals with severe heart diseases, including a history of hospitalization for myocardial infarction or cardiac surgery within the past 3 months, congestive heart failure, severe and unstable arrhythmias, hypertrophic cardiomyopathy, severe aortic valve stenosis, angina, or respiratory difficulties during rest or daily activities; (11) individuals with joint diseases of the hip or knee joints that limit sufficient active range of motion (AROM) for walking, sitting, or squatting. Hip joint AROM < 60° or knee joint AROM < 90°, or knee joint flexion contracture > 30°; (12) individuals with spasticity of the lower limbs, with a modified Ashworth Scale (MAS) score greater than 3; (13) individuals with severe pain when standing, with a pain scale score (Numerical Rating Scale, NRS) greater than 6; (14) individuals known to have severe osteoporosis, with bone density more than 2.5 standard deviations below the average value for young adults, and with one or more osteoporotic fractures; (15) individuals experiencing epileptic seizures.

B. Set-ups and Protocols

The active personalized lower limb exoskeletal robot (Keeogo, Wistron Medical Technology, Taiwan) was utilized in this study. The device was fitted to the participants' limbs with the aim of providing power assistance to their walking ability. It consists of bilateral motors that assist the left and right knees (Fig. 1). The knee motor offers assistance to the participant during specific phases of walking without initiating or terminating movements, while the hip motion of the device is passive [11]. The right and left hips and knees are equipped with angle, angular velocity, angular acceleration, and gyro sensors. We recorded these signals during walking with a sampling period of 120ms.

The participant would receive a training a robot-assisted gait training 40 min/ session, 1 session a day, 2-3 sessions a week, 6 sessions in total. Before each training, the parameters of knee motors would be set according to the participant's motor ability for well supporting (Fig. 2A-C).

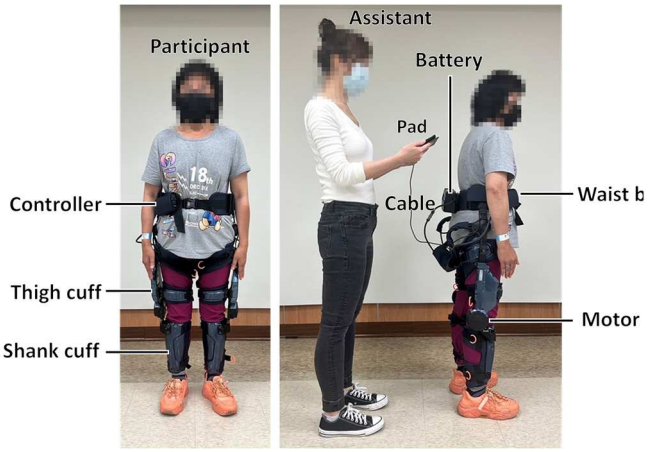

Fig. 1 The active personal exoskeleton robotic device.

C. Kinematics Analysis in Robot-assisted Training Using Cyclograms

The curves depicting angle variations at the hip and knee joints in the sagittal plane (Fig. 2D) were subjected to processing to generate separate hip-knee cyclograms for the right and left limbs. Additionally, the subsequent analysis involved determining various properties from these cyclograms, including the following values:

1. Symmetry of joints[12, 13]: the dimensionless parameter quantifies the similarity between two waveforms,

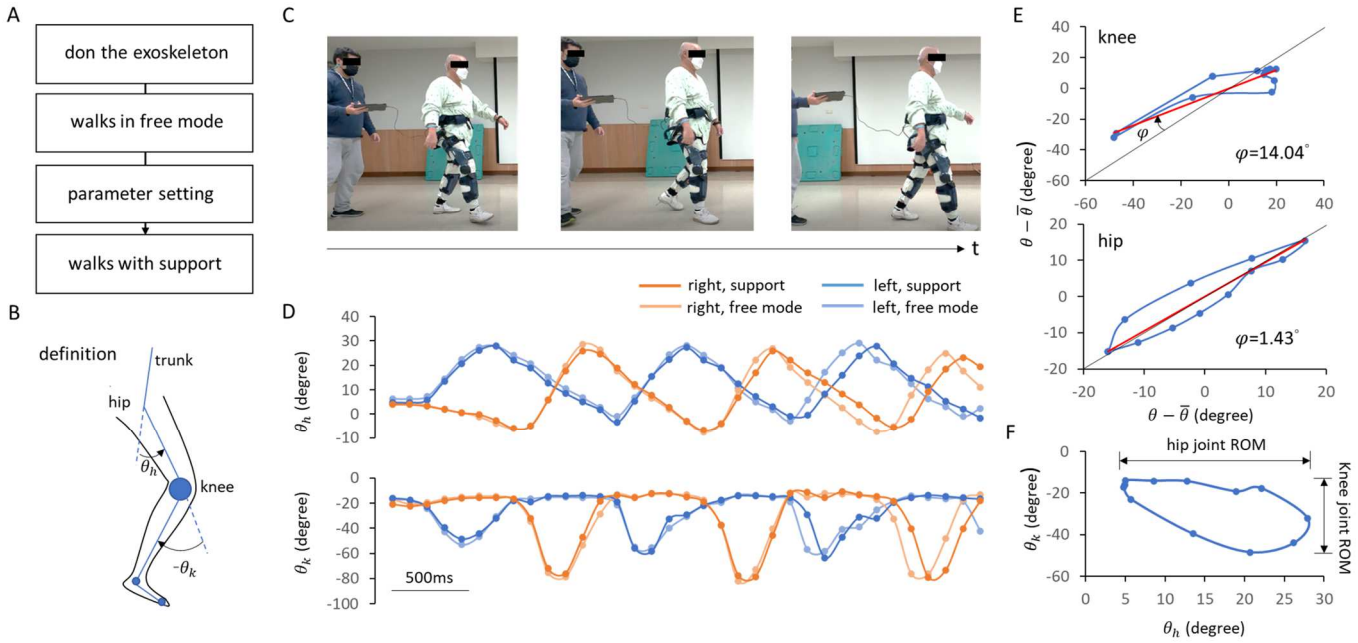

Fig. 2 The experimental protocol and gait analysis. (A) Experimental protocol; (B) Hip and knee angle definition; (C) Signal collection during robot-assisted walking; (D) Signals collected in free mode (no power support) and power supporting mode; (E) Symmetry analysis of hip and knee joints; (F) Inter-joint coordination in a single gait cycle

specifically the angular trends of the right and left legs across gait cycles for each joint of the hip and knee. It is calculated using eigenvector analysis, where the variability around the eigenvector is divided by the variability along the eigenvector. Notably, this parameter remains unaffected by waveform shifts or magnitude differences between the two waveforms (Fig. 2E). A value of 0 indicates perfect symmetry and increasing values of the trend symmetry (TS) parameter indicate higher levels of asymmetry.

$$\begin{Bmatrix} X_R \\ X_L \end{Bmatrix} = \begin{Bmatrix} X_{Ri} \\ X_{Li} \end{Bmatrix} - \begin{Bmatrix} X_{mR} \\ X_{mL} \end{Bmatrix} \quad (1)$$

$$\mathrm{TS} = \frac{emin}{emax} * 100 \quad (2)$$

where the symbols R and L represent the right and left sides, respectively. The variable 'm' denotes the mean value calculated from *'i'* data points within a waveform, where *'i'* represents each individual data point. Additionally, 'emin' and 'eman' represent the minimum and maximum eigenvectors, respectively.

2. Cyclogram orientation (CO)[12, 13]: this feature is characterized by two aspects, the absolute value of angle ϕ formed by the 45° line, which represents perfect interlimb symmetry, and the orientation of the principal axis of inertia, which corresponds to the minimum moment of inertia of the cyclogram. The latter was determined by calculating the eigenvector direction of the inertia matrix derived from the distribution of cyclogram points in the x-y reference system (representing the left joint angle–right joint angle, Fig. 2E). Smaller values of this angle indicate a higher degree of inter joint symmetry, as below:

$$\mathrm{CO} = 45 - (\frac{180}{\pi})\arctan(\frac{e1}{e2}) \quad (3)$$

where e1 and e2 denote the elements of eigenvectors.

3. Cyclogram perimeter (L_i)[5, 9]: The length of the trajectory reflects the average joint velocity and the distance covered by the hip and knee joints. As such, the perimeter can be considered as a measure of the coordination between the hip and knee joints during the gait cycle (Fig. 2F), as below:

$$L_i = \sqrt{\left(\theta_{h_i} - \theta_{h_{i+1}}\right)^2 + \left(\theta_{k_i} - \theta_{k_{i+1}}\right)^2}$$

$$= \Delta t \sqrt{{\omega_{h_i}}^2 + {\omega_{k_i}}^2} \quad (4)$$

where $\theta_{h_i}$and θ_{k_i} represent the hip and knee joint angles, respectively, at point i. The variables ω_{h_i} and ω_{k_i} represent the average angular velocities of the hip and knee joints, respectively, within a specific time interval Δt.

4. *Cyclogram area[5, 9]:* the area of the closed trajectory corresponds to the simultaneous angular variation occurring at the two joints of interest during the gait cycle. A larger area typically signifies a greater conjoint range of angular movements experienced at a specific joint pair throughout a complete gait cycle (Fig. 2F), as below:

$$\text{Area} = \frac{1}{2}\sum_i(\theta_{h_i}\theta_{k_{i+1}} - \theta_{h_i+1}\theta_{k_i}) \quad (5)$$

D. Assessment and Data Analysis

The training efficacy was assessed with outcomes to measure performance change before and after robot-assisted training. The assessment was performed by the other medical licensed physical therapists on the participant without wearing an exoskeleton robot.

The 6-minute walking test (6MWT, distance in meters) was used to evaluate gait function and endurance [14], higher scores (distance walked) means better gait endurance. The lower extremity portion of the Fugl-Meyer assessment (FMA-LE) is the most commonly used clinical assessment tool for identifying motor recovery of the paretic lower limb in patients with stroke [15]. The Berg Balance Test (BBS) is an excellent measurement tool with high reliability and can be used to measure static and dynamic balance in patients with stroke [16]. Timed Up and Go Test (TUG) is also a reliable tool for assessing lower limb mobility in people after stroke [17]. Barthel Index (BI) is one of the most common scales used in clinics to understand the independence of daily activities, ranging from 0 (completely dependent) to 100 (independent) [18]. The EuroQoL-5 Dimension (EQ-5D), a self-reported health status assessment, comprises five dimensions corresponding to mobility, self-care, routine activities, pain or discomfort and anxiety or depression as part of a total health state, with higher scores indicating more severe or frequent problems [19]. The Lawton–Brody instrumental activities of daily living (IADL), which comprises eight items corresponding to making phone calls, shopping, preparing food, housekeeping, laundering, taking pills, using transportation and managing finances, is used to evaluate how patients engage in activities of daily living [20]. The five-meter walking speed (5MWS) assesses longitudinal changes in walking speed after stroke [21].

III. RESULTS

A. Participant Characteristics

Table 1 presents the characteristics of the participants. We recruited three stroke patients whose stroke onset periods were 1, 9, and 23 months, respectively. The affected side for participants #1 and #3 was the left, while participant #2 had a right-side stroke. All participants successfully completed the six training sessions, and no adverse events were observed in the study.

Table 1. Characteristics of stroke patients

Participants	#1	#2	#3
Gender	M	M	M
Age (years)	51	26	54
Affected limb	L	R	L
Time since stroke(months)	1	9	23
mRS	4/3	3/2	3/3
BI	85/95	65/85	70/70
EQ-5D	7/5	8/7	10/10
IADL	3/4	2/2	2/2
BBS	36/47	37/43	39/43
5WMS (s)	7.53/4.78	10.1/7.39	9.12/7.5
6MWT (m)	162/432	31/189	225/270
FMA-LE	21/30	10/18	18/33
TUG (s)	20.35/12.36	25.5/16.34	22.85/15.08

The results of pre-/post- intervention shown in the assessment data.

B. Kinematics Analysis in Robot-assisted Gait Training

Figure 3 illustrates the inter-joint coordination during walking with robot assistance. We compared the robot-assisted walking in free mode versus the power-supported mode, as it was observed that the power-supported mode enhanced the range of motion for hip-knee coordinated gait on the affected side. Additionally, the ranges of inter-joint movement between the

hip and knee increased over time. For instance, the movement ranges during the 3rd and 6th training sessions were greater than those observed during the 1st training session, inparticular the range of knee joint movement.

We conducted a further analysis of the symmetry of the hip and knee joints on both sides, as well as the area, perimeter, and range of joint movement, based on the data presented in Figure 3 and the averaged data collected from the 1st, 3rd, and 6th training sessions as shown in Table 2. The results indicate that the joint symmetry of the hip and knee pairs, as well as the perimeter of inter-joint movement, did not exhibit an increase when power support was provided to the affected side knee joints compared to walking in free mode. However, the results showed an increased area of the hip-knee cyclogram on the affected side in the power support mode. Furthermore, a slight increase in the ranges of joint movements of the hip and knee were observed in participants #1 and #3 on the affected side. These findings suggest that the power provided by the exoskeleton robot to the knees may facilitate specific characteristics of gait function in stroke patients.

C. Effects After Robot-assisted Training

Finally, we analyzed the functional recovery in patients with acute and subacute stroke may exhibit superior outcomes compared to those in the chronic stroke stage, as indicated in

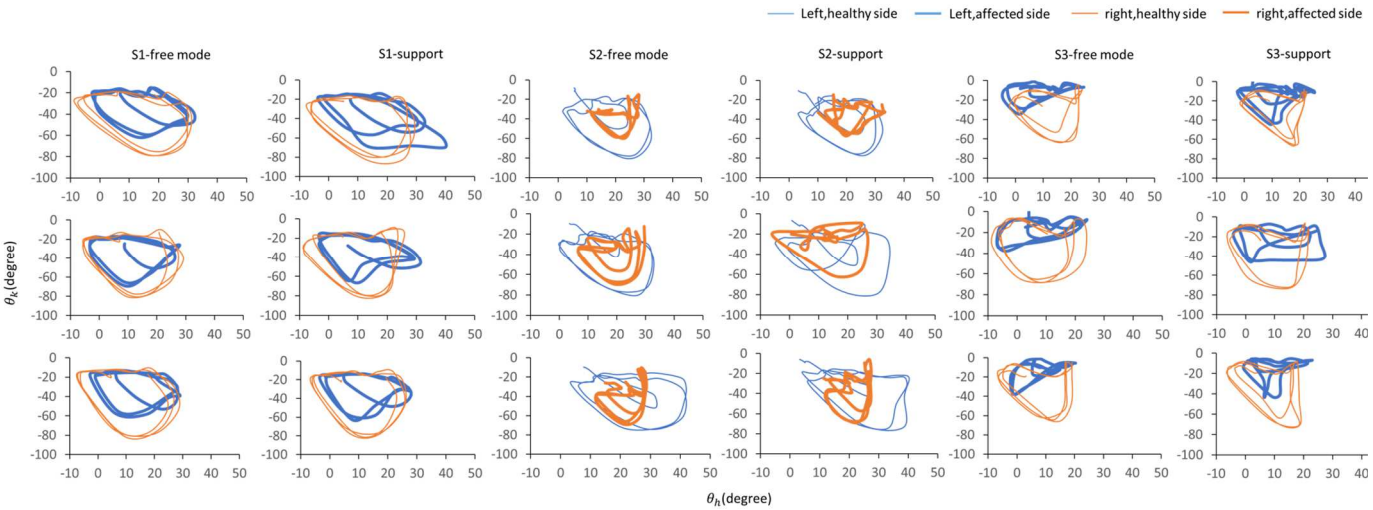

Fig. 3 The cyclograms illustrates the inter-joint coordination across three training sessions, namely the 1st, 3rd, and 6th training sessions, from top to bottom. The thick and thin lines indicate data obtained from the affected and healthy sides, respectively.

Table 2. Gait parameters in the three patient subjects. The results of the kinetics analysis are depicted, with the data presented as the mean (SD).

Table 1. Figure 3 provides a comprehensive overview of the effects on clinical outcomes before and after the training intervention. Following the training program, significant improvements in lower limb function were observed based on clinical assessments, including the Barthel Index (pre-: 73.33±10.4; post-: 83.33±12.58), Berg Balance Scale (pre-: 37.33±15.3; post-: 44.33±23.1), 5-Meter Walk Speed (pre-: 8.92±1.3s; post-: 6.56±1.54s), 6-Minute Walk Test (pre-: 139.33±98.97m; post-: 297±123.73m), Fugl-Meyer Assessment for Lower Extremity (pre-: 16.33±5.69; post-: 27±7.94), and Timed Up and Go Test (pre-: 22.9±25.8s; post-: 14.59±2.03s). However, notable improvements in the modified Rankin Scale, Instrumental Activities of Daily Living, and EuroQol-5D were exclusively observed in patients with acute stroke (Table 1).

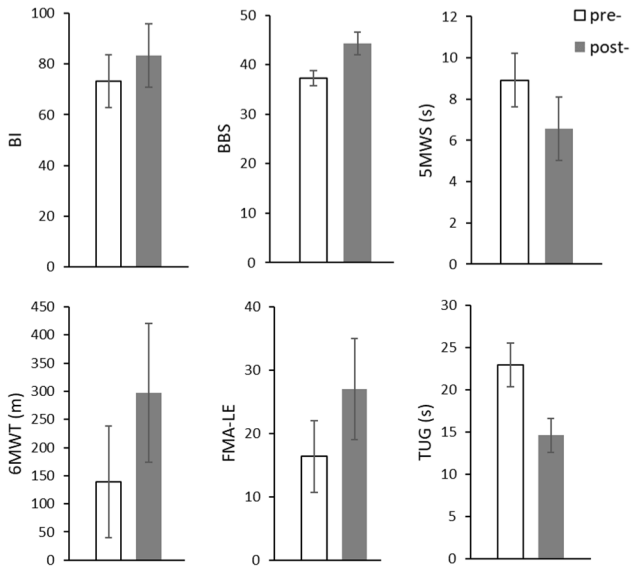

Fig.4 Clinical outcome measurements at baseline and after the 6th robot-assisted walking training. The data are presented as the mean±SD.

IV. Discussion

The present study observed and characterized improvements in spatiotemporal and sagittal joint kinematics as well as the results of clinical assessments following the robot-assisted gait training in participants with stroke. Specifically, lower limb function improved in the results of BBS and TGU but not in mRS, EQ-5D, or IADL."

We found that BBS and TUG demonstrated more effective improvements as compared with other parameters, such as BI, 5MWS, 6MWT, and FMA-LE. The motors of the lower limb exoskeleton robot were designed to compensate for the insufficient torque of knee extensor concentric or eccentric movements in the affected limbs of patients. One previous study has demonstrated that knee extension strength plays a crucial role in determining performance in both static and dynamic balance tests [22]. Furthermore, TUG differs to other walking-speed tests, such as 5MWS and 6MWT, in its functional involvement of the sit-to-stand process [23]. This process requires support through concentric and eccentric movements of the knee extensors, as a previous study have highlighted the crucial role of knee extension force in sit-to-stand [24]. Regarding other assessments of lower limb functions, such as 5MWS, 6MWT, and FMA-LE, which involve coordinated movements of all of the hip, knee, and ankle joints, the assistance of robot that focuses solely on knee support can only partially improve gait functional. BI, IADL, EQ-5D, and mRS are comprehensive evaluations of overall independence. Therefore, robotic support for the concentric and eccentric movements of the knee extensors alone is insufficient to generate a comprehensive impact on overall independence.

In the present study, motor relearning or employment of compensatory mechanisms are observed during testing and training. A sufficient adjustment period is necessary for participants who have not previously used a robotic device for walking assistance. Interestingly, we observed that an adjustment period is also needed following updates to the parameters for knee motor control. Consequently, following robot-assisted gait training, bilateral hip joint excursions and targeted modifications in knee flexion-extension movement may facilitate the adaptation to the use of robotic devices as well as a change of robotic control parameters. However, it should be noted that powered robot-assisted training can also influence gait performance on the unaffected side. The unaffected side may exhibit spontaneous resistance to the external power, resulting in unstable gait and a decrease of symmetry. Additionally, the unaffected side may attempt to compensate or support the affected side, leading to variations in both hip-knee cyclograms on each side.

In recent years, there has been a growing anticipation that a powered exoskeleton could enhance physical performance, even with a limited familiarity with this technology. Our preliminary data in the present study demonstrated a noteworthy improvement in motor function as they gradually gained proficiency in the use of the exoskeleton. This progress has played a crucial role in narrowing the disparity between their initial abilities in operating the robotic device and their performance after the adjustment of robotic parameters. However, further evaluation is needed to determine the optimal

parameters for stroke patients at different stages of functional recovery of gait.

The present study has several limitations that should be addressed carefully. First, the variance in stroke onset time among the enrolled participants may have influenced the study outcomes. To minimize this potential confounding factor, future studies could consider narrowing down the inclusion criteria regarding motor ability, an approach that could reduce bias resulting from spontaneous functional recovery. Second, it is challenging to identify the most suitable parameters for motor control in stroke patients with varying motor functional abilities. Currently, the assessment of gait symmetry during robot-assisted training and parameter testing heavily relies on expert professionals. Development of standardized protocols or algorithms to determine optimal parameters would enhance the objectivity and reproducibility of the findings. Third, the exoskeleton robot may affect patient's gait function event in the free mode and the present study did not explore the relationship between functional recovery and kinematic results, such as the correlation between gait functions and the hip-knee cyclograms obtained without robot before and after treatment. The understanding of the correspondence between functional improvements and specific kinematic patterns will provide valuable insights into the underlying mechanisms of recovery and guide the development of targeted rehabilitation interventions. Finally, the sample size and the types of training tasks employed in this study may limit the ability to draw definitive conclusions regarding treatment effects.

Future research should include a control group and incorporate a wider range of training tasks, an approach that will allow for a more comprehensive evaluation of the treatment effects and enhance our understanding of the efficacy of the intervention. By addressing these limitations in future studies, we can advance our knowledge in the field, improve the validity of the findings, and contribute to the development of more effective rehabilitation strategies for stroke patients.

V. Conclusions

By implementing specific parameter settings in the exoskeleton robot for stroke patients and providing instructions aimed at improving gait symmetry, we conducted a comprehensive investigation of gait characteristics and parameterization derived from active lower limb robot-assisted training. Our study demonstrated a positive impact on facilitating inter-joint coordination within the hip-knee joint movement on the affected side. The observed facilitated inter-joint movement induced by the robot suggests its potential in guiding motor learning processes that are essential for enhancing gait function.

Acknowledgment

This study was supported by the Ministry of Science and Technology, Taiwan (NMRPG3M0442, NSTC112-2218-E-182A-001), and Chang Gung Medical Foundation (BMRPB67). These funding agencies did not involve in the design of the study, data collection and analysis, and drafting of the manuscript. We also appreciated assistants of Hui-Xuan Qiu and Cheng-En Chien for assisting the current experiment.

***Abstract*—Few studies have evaluated postoperative pain in real patients using biosignal sensors. We aimed to develop a prediction model for postoperative pain exacerbation using a wearable electrocardiogram (ECG) sensor and an intravenous patient-controlled analgesia (IV-PCA) device. We collected ECG and IV-PCA data from eight patients who underwent laparoscopic gastrointestinal surgery. Finally, an AutoEncoder model predicted postoperative pain exacerbation with a true positive rate of 60% and a false positive rate of 1.94 times/h.**

I. Introduction

Annually, an estimated 300 million patients undergo surgical procedures [1]. As a result of advancements in surgical procedures and medical technology, minimally invasive surgical techniques, such as laparoscopic surgery, have been established as the gold standard, contributing to a reduction in postoperative mortality and morbidity [2]. However, even laparoscopic surgery can occasionally result in severe postoperative pain [3]. Despite advancements in perioperative analgesia techniques, a recent study revealed that 13% of patients experienced pain ranging from severe to extreme and 46% experienced moderate to extreme pain during the first two weeks following discharge [4]. Unmitigated postoperative pain can contribute to a decrease in quality of life, prolonged hospitalization, and the manifestation of chronic pain, resulting in substantial socioeconomic repercussions [5], [6]. Consequently, the management of postoperative pain continues to be a critical challenge warranting assiduous attention.

Traditional methods for assessing pain, like the Numeric Rating Scale (NRS) and the Visual Analog Scale (VAS), rely on the patient's subjective input [7]. These approaches are difficult to implement in certain groups, like pediatric patients or individuals with altered levels of consciousness. Moreover, they require active participation from healthcare staff, making constant monitoring challenging. Therefore, there is an urgent need for novel, objective ways to evaluate pain in real-time during the postoperative phase.

Previous studies have attempted to assess pain based on physiological signal changes or facial expressions of healthy volunteers exposed to thermal or electrical stimuli [8]–[14]. In contrast, few studies employed real-patient data to evaluate postoperative pain objectively. Two recent studies evaluated postoperative pain in actual patients using physiological data and machine-learning models [15], [16]. These investigations evaluated pain intensity induced by electrical stimuli or bodily movements in post-surgical patients, predicated on 30 minutes of physiological monitoring. The long-term course of postoperative pain intensity in real patients has yet to be studied.

In postoperative patients, small wearable sensors may be desirable for continuous monitoring as they are not in bed all day. To evaluate the long time course of pain intensity, we selected an electrocardiogram (ECG) as a feature to detect pain exacerbation because, in our experience, it is non-invasiveness and less noisy than other physiological signals. In addition, we utilized an intravenous patient-controlled analgesia (IV-PCA) device, a common analgesic modality used in post-surgical patients. When experiencing severe pain, patients can self-administer analgesic dosage by pressing a button of an IV-PCA device. We hypothesized that IV-PCA dose recordings could be used as a pain exacerbation lable during postoperative phase. We conducted a prospective observational study to construct a prediction model for pain exacerbation in post-surgical patients using ECG and IV-PCA records.

II. Methods

After the approval by the Nagoya City University Graduate School of Medical Sciences and Nagoya City University Hospital Institutional Review Board (60-22-0072, October 24, 2022), written informed consent was obtained from all the participants.

A. Participants

We included patients aged 20–90 with an American Society of Anesthesiologists-Physical Status (ASA-PS) of 1–3 who underwent laparoscopic or robotic-assisted gastrointestinal surgery at Nagoya City University Hospital. Patients incapable of conveying pain or utilizing an IV-PCA device as a result of dementia or cerebrovascular disease complications were excluded. Patients with comorbidities that affected their ECG, such as arrhythmia, Parkinson's disease, obstructive sleep apnea syndrome, epilepsy, and diabetic peripheral neuropathy, were also excluded.

B. Data Collection

The collection of data is depicted in Fig. 1. The ECG measurement and IV-PCA infusion were initiated in the post-anesthesia care unit (PACU) and persisted until postoperative

979-8-3503-0067-3/23/$31.00 ©2023 IEEE

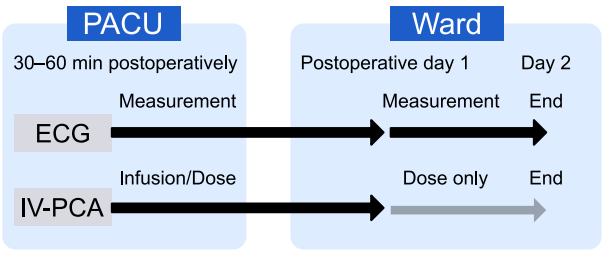

Fig. 1. Flow of Data Collection

day 2. We utilized a GSH761 ECG sensor (Golden Smart Home Technology Corp., Hsinchu, Taiwan, ROC) with a sampling rate of 250 Hz and a COOPDECH Amy PCA (Daiken Medical Co. Ltd., Osaka, Japan) that recorded the time of analgesic doses on a second-by-second basis. Bluetooth was utilized on a smartphone to synchronize the time between the wearable ECG sensor and the IV-PCA device. Patients were managed under general anesthesia with endotracheal intubation intraoperatively. For IV-PCA, fentanyl was administered at a rate of 0.3 μg/kg/h for continuous infusion and 0.3 μg/kg for bolus doses, with a lockout interval of 10 minutes.

C. Preprocessing of ECG

Subsequent to the extraction of ECG data from the sensor, artifacts were removed where the ECG waveforms had not been accurately captured. R waves within the ECG were detected with an algorithm predicated on first-order derivatives for peak identification. R-R intervals (RRIs) were ascertained through the measurement of temporal duration between consecutive R waves. A temporal window of three minutes was deployed for the computation of heart rate variability (HRV) features corresponding to each R wave.

D. Input Features of HRV

The three domains of HRV were used for input features.

- **LFnu :** Power of the low-frequency band (0.04–0.15 Hz) divided by total power.
- **HFnu :** Power of the high-frequency band (0.15–0.4 Hz) divided by total power.
- **LF/HF :** The ratio of the low-frequency band power to the high-frequency band power.

When the patient experiences pain exacerbation, the dominant sympathetic nervous tone would induce increased LFnu and LF/HF and decreased HFnu. If a bolus dose of fentanyl were administered, the sympathetic nervous tone would be attenuated.

E. Definition of Pain Exacerbation

Timing of pain exacerbation was defined as the times when patients self-administered IV-PCA doses. Given that intravenous fentanyl is anticipated to provide analgesia within a few minutes, we developed a prediction model that could detect HRV abnormalities 15 minutes prior to the IV-PCA dose.

III. MODEL

A. Architecture

Since we believed that patients would not experience severe pain for long periods of time with proper use of IV-PCA, the AutoEncoder (AE) model, an anomaly detection algorithm, was employed to classify pain exacerbation or not. As shown in Fig. 2, AE has inputs and outputs of the same dimension and hidden layers between them [17]. The AE model is trained to minimize a mean squared error (MSE), which is shown as follows:

$$L = \frac{1}{k}\sum_{i=1}^{k}\left\{\frac{1}{n}\sum_{j=1}^{n}(x_{i,j}-\hat{x}_{i,j})^2\right\}$$

In the above equation, k is the number of input features, $x_{i,j}$ is the input features $\{x_{i,1}, x_{i,2}, \ldots, x_{i,n}\}$, n is the length of the input sequence, and $\hat{x}_{i,j}$ is the restored features $\{\hat{x}_{i,1}, \hat{x}_{i,2}, \ldots, \hat{x}_{i,n}\}$ by the AE model.

We used the three HRV features with 60 sequential length. The network architecture had a 60×3 input, a 60×3 output that duplicates the input.

B. Training

The AE model was trained to minimize the MSE loss function. During the validation of each patient, the model was trained using HRV data derived from all patients except the one under validation (a leave-one-out-validation method). The training dataset included only the HRV data where IV-PCA doses were not administered within 60 minutes. We constructed the AE model with three hidden layers, with dimensions of 40, 20, and 40 units, respectively. The model was trained using the Adam optimizer, with a learning rate set at 0.002.

C. Validation and Test

For evaluation, reconstruction error (RE) was defined as the mean absolute error (MAE) between the input and output features.

$$RE = \frac{1}{k}\sum_{i=1}^{k}\left\{\frac{1}{n}\sum_{j=1}^{n}|y_{i,j}-\hat{y}_{i,j}|\right\}$$

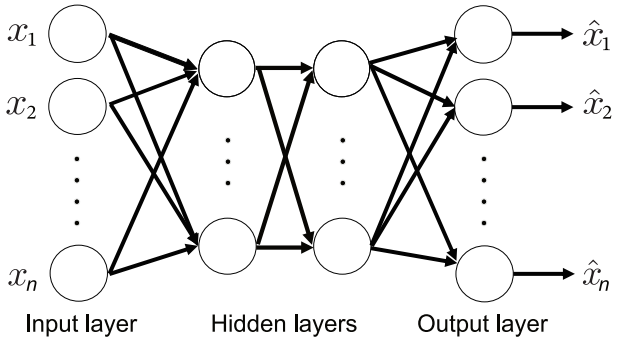

Fig. 2. AutoEncoder Model

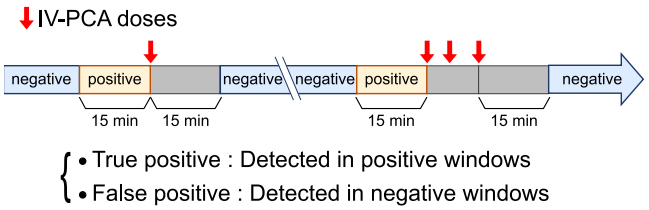

Fig. 3. Positive and Negative Windows of the Dataset

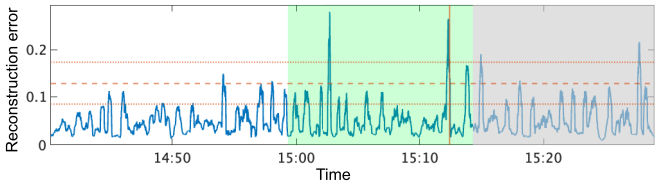

Fig. 4. Detection of Pain Exacerbation in Patient 5

The RE threshold ($\overline{RE}$) in each patient is required to detect pain exacerbation. Given the preliminary nature of this analysis, the limited cohort size might entail a substantial dispersion in individual RE values. Thus, we partitioned the time-series data for each patient into two segments in a 1:3 ratio to determine the ($\overline{RE}$). The initial 25% of the ECG data were employed to determine the $\overline{RE}$ for pain detection. Then, the latter 75% of the ECG data were utilized to evaluate the model performance.

If pain was detected, subsequent detection was delayed 15 minutes. In addition, we ensured that there would be no detection 15 minutes after each IV-PCA dose. The positive and negative windows of the test dataset are depicted in Fig. 3. The positive window was defined as the 15-minute period before each IV-PCA dose. If a second dose of IV-PCA was administered within 15 minutes, only the initial dose was used for the positive window. The negative window was defined as the period during which no IV-PCA doses were administered within 15 minutes before or after. For evaluating the model, we calculated the true positive rate (TPR) when pain was detected in a positive window and the false positive rate (FPR) when pain was detected in a negative window calculated as times/h.

We utilized an algorithm that detects pain exacerbation when the RE exceeds 90%–95% of its confidence interval ($\overline{RE}$) for 10–30 seconds. Through trial and error with different threshold patterns, the upper and lower limits of the confidence interval and duration were determined. In each patient, the GridSearch was employed to identify the $\overline{RE}$ to maximize the difference between the TPR and the FPR within the validation dataset.

The preprocessing of ECG was conducted using MATLAB 2022b (Mathworks Inc.), while other computations were carried out using Python 3.10.8 and PyTorch 1.13.1.

IV. RESULTS

We collected ECG and IV-PCA data from eight patients between December 2022 and February 2023 to construct a prediction model. Table I displays patient characteristics, the number of IV-PCA doses self-administered, and the duration of recorded ECG data. Due to postoperative nausea and vomiting, ECG measurements and IV-PCA was stopped for Patient 4. In patient 7, available ECG data were limited due to inaccurate measurements. The overall performance of the model was 60% for TPR and 1.94 times/h for FPR (Table II).

Fig. 4 shows the correct detection of pain exacerbation in patient 5. The green box indicates the positive window. The gray box indicates the 15 minutes after IV-PCA dose use. The vertical red line indicates the time the model detected pain exacerbation. In this patient, 94% of $\overline{RE}$ (a red horizontal dashed line) and 13 seconds duration were used. The horizontal red dotted lines indicate the standard deviation of the RE.

V. DISCUSSION

The AE model predicted postoperative pain exacerbation with a TPR of 60% and an FPR of 1.94 times/h. We previously reported a Self-Attentive AE model with a TPR of 54% and an FPR of 1.76 times/h using the same dataset [18]. The current results using the AE model achieved a higher TPR, but also a higher FPR. Sixty percent of TPR seems to be a reasonable performance in this preliminary result despite of the small dataset. Considering that the standard lockout time for IV-PCA with fentanyl is 10 minutes, suggesting six times per hour as a safe maximum dose, our proposed model is clinically safe in terms of relatively high FPRs. Nevertheless, FPRs may need to be decreased for clinical application. Since there is a trade-off between the TPRs and FPRs, the beneficial performance for post-surgical patients needs to be clarified in the future.

Few studies have evaluated postoperative pain in real patients using biosignal sensors. Naeini *et al.* [15] classified postoperative pain into five levels, downsampled from 11 levels of the NRS, using an ECG-derived machine learning model in post-surgical patients. Aqajari *et al.* [16] also classified postoperative pain using a machine learning model using skin resistance features. We used an IV-PCA record as a pain label assess continuous pain intensity in contrast to subjective scales like the NRS and the VAS [18]. The strength of our modality is its ability to evaluate pain over extended time periods.

Some limitations of our study should be noted. First, the number of participants were small. Second, the method of determining the $\overline{RE}$ used in this study may not be robust. We used the initial 25% of the ECG data and a small number of IV-PCA doses data to determine the $\overline{RE}$. The blood concentration

of fentanyl could not attain a steady state immediately after the start of IV-PCA. There may also be residual effects of general anesthesia. We are investigating an algorithm to determine thresholds for each patient on a preoperative ECG. Finally, we excluded some patients who could not express pain, could not use an IV-PCA device, or had comorbidities that affected their ECG.

VI. CONCLUSIONS

We constructed a prediction model for postoperative pain exacerbation using a timely dataset of ECG and IV-PCA records. In this preliminary analysis, the AE model achieved a higher TPR, but also a higher FPR than our previous model [18]. We are going to increase data and compare multiple models, such as principal component analysis and other deep learning models.

Abstract — **This study explored directional connectivity networks during hand movement training in stroke patients using 8 conditions combining mirror therapy, robot-assisted bimanual therapy, and object manipulation. The findings revealed that mirror therapy and robot-assisted bimanual therapy decreased interhemispheric inward connectivity to the affected motor cortex in the left-hand paralyzed patient, reducing inhibitory control. Conversely, these interventions increased interhemispheric inward connectivity in the right-hand paralyzed patient, suggesting enhanced excitatory connectivity. The results emphasized the influence of neurorehabilitation methods, hemiparesis severity, and affected side on interhemispheric connectivity. Further research is needed to develop personalized rehabilitation strategies based on directional connectivity measures.**

I. Introduction

Stroke, the second leading cause of death worldwide, results in approximately 5.5 million annual fatalities [1]. Even for survivors, up to 50% experience long-term disabilities such as hemiplegia and higher-order cognitive dysfunction. The recovery of hand functions induced by stroke is slower and more difficult than the lower limb due to the high dexterity [2, 3]. Therefore, it is vital of importance to investigate efficient rehabilitation strategies to facilitate stroke recovery.

In the field of hand motor rehabilitation for stroke patients, innovative approaches such as mirror therapy (MT), bimanual therapy, robot-assisted therapy, and combination therapy have demonstrated effectiveness in promoting the recovery of hand function [4-6]. However, there remains a lack of comprehensive understanding regarding the specific impact of each neurorehabilitation method on brain recovery, the identification of the patients who benefit the most from these interventions, and the optimal application methods [7].

Based on the previous studies highlighting imbalanced interhemispheric interaction in stroke patients [8-11], the objective of this study is to elucidate the effects of MT, robot-assisted bimanual therapy (RT), and robot mirror therapy (RMT) on the directional interhemispheric connectivity to the affected motor cortex using EEG during hand motor training. Interhemispheric interactions refer to the mechanism of neural circuitry in which the two hemispheres of the brain inhibit each other to perform unilateral movements, such as moving only one hand. After a stroke, this balance of interhemispheric inhibition is disrupted, resulting in increased inhibition from the unaffected hemisphere and decreased activity in the affected hemisphere. This disruption of interhemispheric interactions in bilateral motor cortices has been considered as the cause of stroke-induced hemiplegia, leading to impaired voluntary movements of the affected hand. Based on this hypothesis, an effective neurorehabilitation strategy could reduce excessive motor cortical connectivity from the unaffected side to the affected side.

To investigate these concepts, we examined EEG changes in the directional cortical connectivity of both healthy participants and stroke patients during hand movements under various therapeutic interventions. Additionally, we conducted subgroup analyses based on the severity of hemiplegia and the laterality of the affected hand to explore appropriate target patient populations for these therapeutic strategies.

II. Methods

A. Participants

Electroencephalography (EEG) data were collected from a total of 37 healthy young adult individuals and 46 stroke patients at Chang Gung Memorial Hospital, Kaohsiung

979-8-3503-0067-3/23/$31.00 ©2023 IEEE

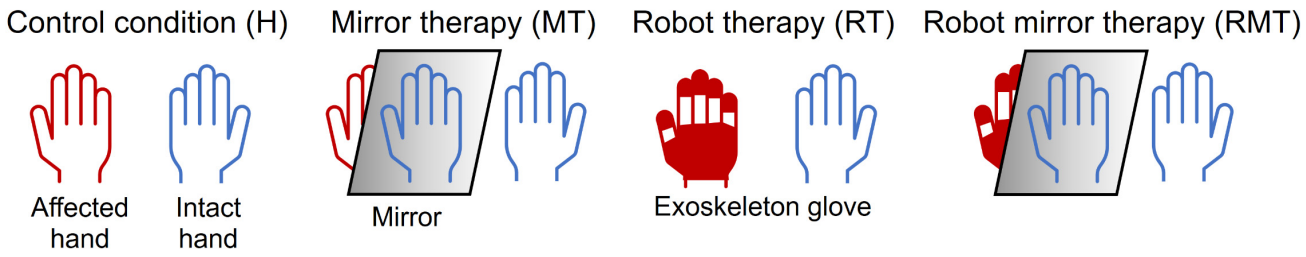

Fig. 1 Experimental conditions for therapy and control. Three types of therapy were employed: Mirror therapy (MT), Robot therapy (RT), and Combined robot-mirror therapy (RMT). The control condition involved the hand without mirror and robot (H). Each condition was tested with and without object manipulation, resulting in a total of 8 conditions.

Medical Center. Detailed inclusion and exclusion criteria for patients can be found in our previous report [7]. The stroke patient group was further divided into subgroups based on the laterality and severity of motor impairment. Specifically, there were 23 patients with right-hand hemiplegia (left-lesional strokes) and 23 patients with left-hand hemiplegia (right-lesional strokes). Patients within each hemiplegia group were classified into subgroups of severe and moderate motor impairment, based on their Brunnstorm recovery stage (BRS) scores in the distal part of the upper extremities [12]. The severe subgroup included patients with BRS II and III, with 12 patients for right-hand hemiplegia and 15 patients for left-hand hemiplegia. The moderate subgroup comprised patients with BRS IV and V, with 11 patients for right-hand hemiplegia and 8 patients for left-hand hemiplegia. The dominant hand of all subjects, including both healthy controls and patients, was the right hand.

The experimental protocol received approval (IRB number: 201900537A3), and written informed consent was obtained from all participants. All methods adhered to the regulations of the Human Subjects Research Act and guidelines of the Declaration of Helsinki 1975.

B. Experimental conditions

The EEG data were recorded using a mobile dry electrode EEG recording device (DSI-24 system; San Diego, CA, USA) with a sampling rate of 300 Hz. The scalp electrodes were positioned according to the standard 10-20 system channel arrangement, with reference electrodes placed on both earlobes.

Participants were seated in front of a table and placed both hands on the table. They performed slow, bilateral finger extension and flexion movements for a minimum duration of 60 s under eight different intervention strategy conditions. We employed a 2 (with vs. without mirror) × 2 (with vs. without robot assistance) × 2 (with vs. without object manipulation) factorial design to determine the intervention conditions (Fig. 1). The order of the training conditions was randomized, and each condition was applied once. For healthy participants, the assignment of moving either their right or left hand was randomized to mimic the other side of the hand as the affected side. Throughout the exercise, all participants were instructed to maintain their gaze on the affected or assumed affected side of the hand.

Fig. 1 depicts the combinations of mirror therapy (MT), robot therapy (RT), mirror and robot therapy (RMT) utilized in this study. MT involved participants focusing on their unaffected hand's reflection in the mirror while performing finger movements, creating an illusion of movement in the affected hand. The visual feedback provided by MT, simulating synchronized movement of the affected hand with the unaffected hand, is considered to promote the reorganization of the motor neural network [4]. RT involved participants wearing a sensor glove on their intact hand and a wearable exoskeleton hand robot (HS 001, Rehabotics Medical Technology Corporation, Taiwan) on their affected hand, facilitating passive movement. The RMT involved participants performing hand movements as in the RT condition. However, a mirror was positioned between the two hands, allowing participants to observe the reflected image of the intact hand during the exercise. This combination provided both visual and proprioceptive feedback, further strengthening the benefits of the intervention in stroke motor rehabilitation [5]. Additionally, the object condition (O) involved participants simultaneously manipulating plastic cups with each hand. These interventions aimed to explore differences in cortical connectivity during motor rehabilitation.

C. Pre-processing and directional connectivity analysis

To investigate the directional connectivity between brain regions, we employed a generalized orthogonalized partial directed coherence (gOPDC) approach [13]. This analysis was applied to the selected channels of EEG data recorded from frontal, central, parietal, and occipital cortices (F3, F4, C3, C4, P3, P4, O1, and O2). The C3 and C4 electrodes are positioned

above the primary sensory-motor cortices of the right and left hands, respectively, which were chosen as the target motor regions that receive interhemispheric neural signals to perform finger movement.

The recorded EEG data was firstly pre-processed using EEGLAB toolbox [14] under a MATLAB (MathWorks Inc., Natick, MA, USA) environment to remove EEG artifacts such as electrooculogram. Specifically, the raw EEG signals underwent a high-pass filter at 1 Hz, which would results in the lowest rejection threshold for non-EEG independent components [15] and improves the quality of the independent component analysis (ICA) [16] decomposition performed thereafter. Then, the line noise was removed with the 'cleanline' and 'clean_rawdata' under the condition, and Artifact Subspace Reconstruction was conducted with a default parameters to automatically modify the bad data. Furthermore, ICA, a feature extraction method often used for EEG artifact removal, was performed to decompose the EEG data into multiple components. Here, 'ICLabel' function was used to automatically label the components into several signal-type categories based on dominant type of signals components have. Of classified components, only component labeled 50 % or more as Brain were selected and other components were rejected as artifacts. Finally, cleaned data was segmented into 1-second epochs, overlapping 0.5 second for each (i.e., an n-second signal will be cut into 2n-1 epochs).

After pre-processing the data, a multivariate autoregressive (MVAR) model [17] was calculated for each condition. The weight matrix A_r of the p-th order MVAR model for the n-point time series data $y_i(n)$ $(i = 1, \dots, M)$ recorded from M measurement points (channels) is determined by the following equation:

$$\begin{bmatrix} y_1(n) \\ \vdots \\ y_M(n) \end{bmatrix} = \sum_{r=1}^{p} A_r \begin{bmatrix} y_1(n-r) \\ \vdots \\ y_M(n-r) \end{bmatrix} + \begin{bmatrix} w_1(n) \\ \vdots \\ w_M(n) \end{bmatrix} \quad (1)$$

$$A_r = \begin{bmatrix} a_{11}^r & \dots & a_{1M}^r \\ \vdots & \ddots & \vdots \\ a_{M1}^r & \dots & a_{MM}^r \end{bmatrix} \quad (2)$$

Here, w_i represents the error between the estimated and observed measurement values. The model order p was determined for each dataset using the ARfit toolbox [18]. The estimated optimal model orders ranged from 3 to 6, with a median value of $p = 4$, indicating that the neural network model could be established within the time lag of 13 ms.

The gOPDC is an extension of the partial directed coherence, designed to capture effective connectivity in neuro-physiological signals. It addresses the limitations of the partial directed coherence by accounting for variations in signal amplitude and mitigating the influence of volume conduction [13]. The gOPDC is defined as follows:

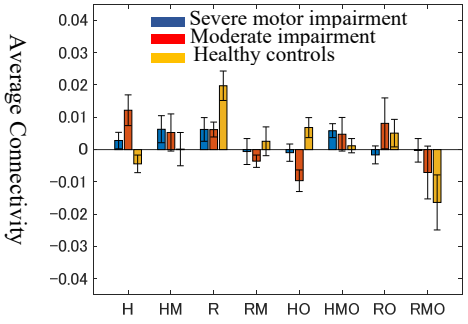
$$gOPDC = \frac{1}{\lambda_{kk}^2} \frac{|Real\{A_{kl}(n,f)\}|}{\sqrt{a_l^H(n,f)\,\Sigma_w^{-1}\,a_l(n,f)}} \cdot \frac{|Imag\{A_{kl}(n,f)\}|}{\sqrt{a_l^H(n,f)\,\Sigma_w^{-1}\,a_l(n,f)}} \quad (3)$$

$$A(n,f) = I - \sum_{r=1}^{p} A_r(n) z^{-r}\big|_{z=e^{j2\pi f}} \quad (4)$$

I is the identity matrix, a_l represents the l-th row vector of A_r, H denotes the Hermitian transpose, and A_{kl} represents the element in the k-th row and l-th column of $A(n,f)$, indicating the weight from channel l to channel k.

We assessed interhemispheric connectivity by calculating cumulative gOPDC values targeting the affected motor area using channels in the contralateral hemisphere. Specifically, in a comparison of right hand hemiplegia patients and right hand motor healthy controls, for the motor cortex corresponding to the right hand (C3), we summed the inward connectivity from channels F4, C4, P4, and O2 to C3 and subtracted the outward connectivity from C3 to F4, C4, P4, and O2. In a comparison of left hand hemiplegia patients and left hand motor healthy controls, for the motor cortex corresponding to the left hand (C4), we summed the inward connectivity from channels F3, C3, P3, and O1 to C4 and subtracted the outward connectivity from C4 to F3, C3, P3, and O1. This approach allowed us to evaluate interhemispheric connectivity patterns focused on the affected motor area, without being influenced by the specific lesion locations found in individual patients.

The strength of the inward interhemispheric information flow was assessed for each condition in both the alpha band (8-12 Hz) and the beta band (13-30 Hz) within the subgroups of severe or moderate motor impairment. The obtained strengths of the connectivity among two patient groups and healthy participants were shown in a bar graph and qualitatively assessed. We further conducted a three-way repeated-measures analysis of variance (ANOVA) and multiple comparisons to analyze the data of the patients, with factors including the presence of mirror, robot, and object in the intervention. All statistical analyses were performed using MATLAB and Microsoft Excel. All data were represented as mean and standard error and a p-value less than 0.05 was considered statistically significant.



III. Results

A. gOPDC measures of interhemispheric connectivity

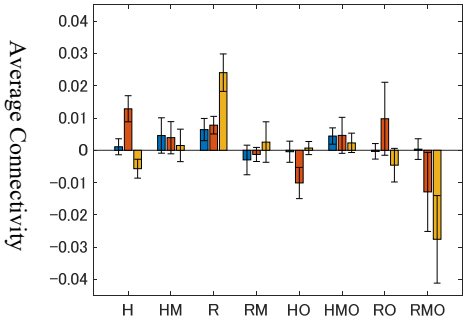


Fig. 2 illustrates the strength of directed interhemispheric connectivity across all combinations of conditions. Considering the impact of excessive inhibitory control from the unaffected side to the affected side motor cortex on stroke-induced motor impairment [8-10], we defined the meaningful effect after rehabilitation as an intervention that reduces inward interhemispheric connectivity to the affected motor cortex. Consistent with this notion, the inward connectivity tended to be higher in stroke patient group (blue and red bars) compared to healthy control group (yellow bars) in the most combinations of intervention strategies, indicating increased control of the affected motor cortex by the unaffected hemisphere. Nevertheless, the results also showed the connectivity changes varied among different combinations of intervention strategies; it is necessary to investigate the individual effects of each intervention.

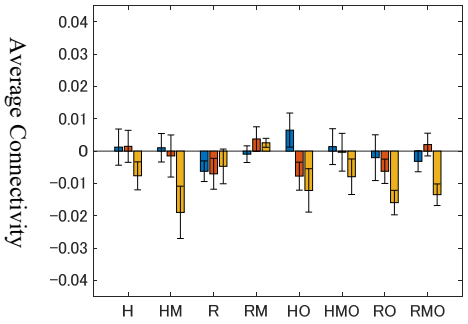
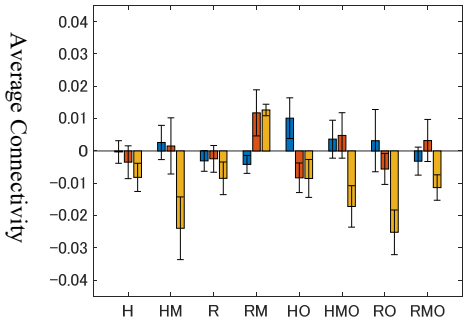
B. Effects of different intervention strategies on interhemispheric connectivity to affected motor cortex

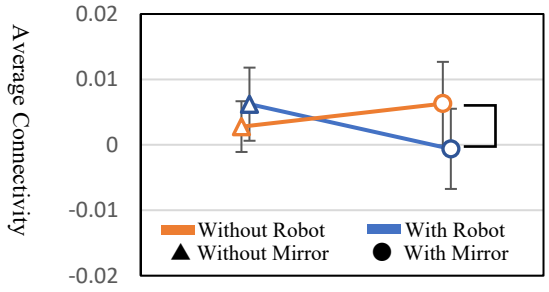


The impact of different intervention strategies on interhemispheric connectivity to the affected motor cortex varied depending on the severity of paralysis and the laterality of the affected hand. We observed a significant main effect only in the case of MT and an interaction between MT and RT. However, no significant interactions were observed across mirror therapy, robot therapy, and the use of objects. Since there were no significant main effects and interactions related to the use of objects, the subsequent results presented in Figs. 3 and 4 depict the interactions between MT and RT in the absence of object use. We observed a significant interaction between MT and RT in the condition of left-hand movement, specifically in the alpha wave connectivity, among patients with severe motor impairment ($F = 6.937$, $p = 0.021$; Fig. 3a). Although not statistically significant, a similar trend was also observed in the beta-band connectivity. Post-hoc multiple comparisons revealed a significant reduction in inward connectivity in RMT, compared to MT alone without incorporating RT. However, in the case of right-hand movement, there was no statistically significant interaction with any combination of the factors (Fig. 3b).

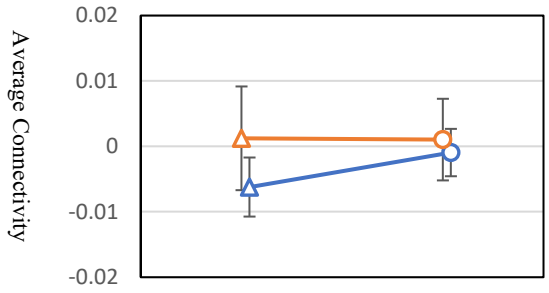


(a) Alpha band connectivity during left hand movement

(b) Beta band connectivity during left hand movement



(c) Alpha band connectivity during right hand movement



(d) Beta band connectivity during right hand movement

Fig. 2 Strength of inward interhemispheric connectivity to the affected motor area. The bar colors represent different participant groups: blue for patients with severe motor impairment, red for patients with moderate impairment, and yellow for healthy controls. The intervention conditions are labeled as follows: Control condition (H), mirror therapy condition (HM), robot therapy (R), combined mirror and robot therapy (RM). Object manipulation condition is indicated with(O).

(b) Alpha band connectivity during right hand movement in patients with severe motor impairment without object manipulation

Fig. 3 Alpha-band inward interhemispheric connectivity to the affected motor area during hand movement in patients with severe motor impairment. Left paralyzed patients (a) show a significant interaction, while right paralyzed patients (b) do not. Circle and triangle markers represent data with and without MT, respectively. Blue and orange lines represent data with and without RT, respectively. Blankets indicate significant differences in post-hoc multiple comparisons.

(a) Beta band connectivity during left hand movement in patients with moderate motor impairment without object manipulation

(b) Beta band connectivity during right hand movement in patients with moderate motor impairment without object manipulation

Fig. 4 Beta-band inward interhemispheric connectivity to the affected motor area during hand movement in patients with moderate motor impairment. Left paralyzed patients (a) show a significant decrease of connectivity with a use of RT, while right paralyzed patients (b) showed opposite main effect. Circle and triangle markers represent data with and without MT, respectively. Blue and orange lines represent data with and without RT, respectively. Blankets indicate significant main effect.

In patients with moderate motor impairment, we observed a significant main effect of MT on beta band connectivity for both sides of hand movement. However, the impact of MT on the directional connectivity differed between the affected sides. During left-hand movement, MT significantly reduced the inward connectivity to the affected motor cortex, regardless of the involvement of RT ($F = 7.694$, $p = 0.028$; Fig. 4a). A similar trend was observed in alpha wave connectivity. In contrast, MT increased the inward connectivity to the affected motor cortex during right-hand movement, regardless of RT ($F = 5.179$, $p = 0.046$; Fig. 4b).

IV. Discussion

The directional connectivity analysis of EEG data during hand motor task revealed the influence of neurorehabilitation methods, hemiparesis severity, and affected side on interhemispheric connectivity in healthy participants and stroke patients. These findings suggest that the combination of MT and RT significantly decreased interhemispheric inward connectivity to the affected motor cortex in the left-hand paralyzed patient, suggesting the reduced inhibitory control from the intact hemisphere. These findings may provide additional benefits of RMT in improving neural networks in patients with severe paralysis. In case of patients with moderate paralysis on the left hand, MT was found to reduce the interhemispheric connectivity strength regardless of RT, while the RMT showed a greater reduction in interhemispheric connectivity in severely paralyzed patients compared to MT alone. This difference can be attributed to the range of hand motion in patients with different motor impairments. Severe paralysis severely limits finger mobility, and the combined feedback from proprioception and visual input during robot assisted finger movement may have significantly reduced inward interhemispheric connectivity beyond the effects of visual feedback alone. In patients with moderate paralysis, either visual or proprioceptive feedback could enhance incomplete finger movement, leading to a reduction in inward interhemispheric connectivity. There have been debates regarding the effectiveness of MT [19] and robot-assisted

therapy [6, 20] for motor recovery. Inconsistent results may arise from the residual motor ability of patients at baseline.

The contrasting trend of increased inward connectivity during right-hand movement suggests differences in the cortical connectivity network based on hand dominance. Previous studies using transcranial brain stimulation have reported variations in interhemispheric connectivity strength depending on the dominant or non-dominant motor sides [21, 22]. Our findings with healthy participants support this trend, demonstrating enhanced inward connectivity to the contralateral motor area during right-hand movement (Figs. 2cd) compared to the left-hand movement (Figs. 2ab). In the case of dominant hand movement, both inhibitory and excitatory interhemispheric control mechanisms [8, 10] may contribute to the summed inward connectivity. However, it is important to acknowledge the limitation of our study, as the gOPDC measure cannot differentiate between the polarity of signal transfer, such as GABAergic inhibitory or glutamatergic excitatory neuron activities. Further investigation using longitudinal datasets is necessary to gain a deeper understanding of the characteristics of interhemispheric directional connectivity throughout the different stages of stroke motor impairment recovery.

V. Conclusions

We examined the differences in directional connectivity networks during finger motor functional training using various intervention strategies, including MT, RT, and object manipulation. The contribution using the gOPDC method to analyze motor cortical networks in stroke patients is state-of-the-art in the present study. Our findings revealed that the choice of neurorehabilitation methods, the severity of motor function, and the affected side in the brain can influence interhemispheric connectivity during motor training. Analyzing information transmission between affected and unaffected motor cortices through network connections offers valuable insights for designing personalized rehabilitation programs and promoting recovery.

However, it is important to acknowledge that the current connectivity measure used in this study does not differentiate between inhibitory and excitatory interhemispheric interactions. Additionally, the tendencies in causal connectivity indices differed between patients with right hemiparesis and left hemiparesis. Further research is needed to develop patient-oriented rehabilitation strategies that leverage directional connectivity measures to optimize outcomes.

***Abstract* — With the recent development of virtual reality technology, sensory information in virtual space could be a candidate for experimental stimuli in the field of cognitive neuroscience. Specifically, auditory and tactile stimuli, which is spatiotemporally synchronized to visual information of the space and body delivered using a head-mounted display (HMD), can be presented in controlled way using headphones, tactile stimulators (e.g. Kanayama et al., 2019), etc.. During such a sensory stimulus presentation, we could measure any neuronal responses, and realize cognitive neuroscience study in the experimental setting impossible in real world. Such a method involves fixing the HMD to participant's head and using the actuator near participant's body, which suggests possible contamination of greater noise to recorded neuronal responses compared to that in experiments without virtual reality. In the case of high-density EEG measurements on the scalp, there should be interference to the electrodes from the fixation band of HMD to the participant's head, electromyogram (EMG) noise induced by participant's head movements, and noise emitted by the HMD device itself.**

I. INTRODUCTION

In recent decade, virtual reality technology has been dramatically developed. On December 2012, Oculus VR, LCC has been released a head-mounted display (HMD), Oculus Developer Kit for video game developers, and then on January 2016, the consumer version has started to sell. Before the consumer versions of HMDs were sold, some neuroscience researchers, who especially has been interested in human body recognition, used HMD for their psychological experiments [1,2] controlling body image in virtual reality environment. However, for the neuroscience study using scalp EEG, HMD was not easily used because of interference with electrode attached onto the participant's head, which led the neuroscience researcher avoid using HMD for their VR experiment with EEG measurement (e.g. using a large rear-projection screen [3]). Otherwise, scalp-EEG measurement was omitted from the experimental settings for embodiment study using HMD [4]. Although HMD and Scalp-EEG measurement are not compatible with each other, fMRI as alternative way to conduct cognitive neuroscience study has more critical limitation that the participant can't rotate own head to see around the VR environment. Because cognitive neuroscience study using fMRI also has another limitations such as the requirement to lie on a bed during scanning, it is considered that the most feasible method at present is to increase the EEG measurement accuracy on the combination use of scalp-EEG and HMD.

Altogether, when we conduct any cognitive neuroscience study for VR using HMD, the following two points are important.

1. Avoiding interference on scalp EEG electrodes by HMD
2. Quantitatively clarify the extent to which noise is affected by HMDs

For the first point, our previous study has made the settings avoiding the HMD interference on EEG electrode by fixation of HMD on the back of the neck and hanging it on the ceiling (Fig.1) [5]. For the second point, some previous research has demonstrated that HMD does not necessarily add any external noise to make the recorded EEG data unusable. A study has found a significant condition difference on visual- and somatosensory evoked potentials and reported the signal-to-

979-8-3503-0067-3/23/$31.00 ©2023 IEEE

noise ratios [6]. An our previous study also demonstrated the target event-related spectrum power (ERSP) showed statistical difference of the experimental condition (spatially congruency of visuo-tactile stimulation; congruent vs. incongruent) as the similar previous studies showed. However, there is no study to show how much the noise contaminated by using HMD and VR contents has any impact on the detection of condition difference. Actually, in almost all cases, we tried to exclude the noise contamination, and have clean data during the experiment, which requires the intentional data record with typical noise as a template. In this study, using the noise waveforms recorded as a template of VR related noise (electrode movement noise based on the head/neck movement), the support-vector machine classification performances were evaluated using original EEG data and noise contaminated EEG data.

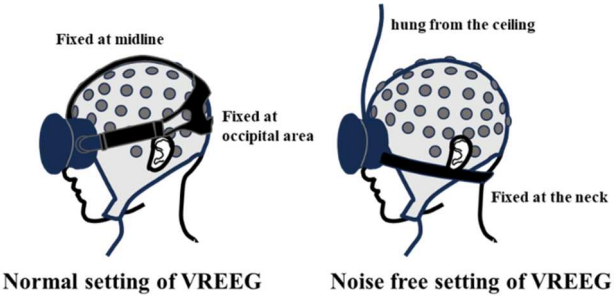

Fig. 1 Schematic illustration depicting the setup of wearing VR and EEG electrode cap.

II. Material and Methods

A. Experimental Procedures

The EEG datasets were obtained from 32 healthy individuals by the previous study [5] that aimed to detect the theta and gamma oscillatory activities during rubber hand illusion paradigm. To induce the illusion, we have used LEDs as visual stimuli and vibration using bone-conducting earphone as tactile stimuli. These stimuli were presented simultaneously, while the spatial position was changed between condition. In the congruent condition, if LED as a visual stimulation emitted at the index finger, tactile stimulation was delivered on the identical finger (the index finger), whereas in the incongruent condition, if LED as a visual stimulation emitted at the index finger, tactile stimulation was delivered on the different finger (the ring finger). The almost same experiment was conducted with HMD. The details of the experimental design and procedure can be available in the method section in the published previous paper [5].

B. EEG Data Analysis

The recorded EEG waveforms using actiCHamp (Brainproducts GmbH, Munich, Germany) from 63 electrodes with 1000 Hz sampling rate. At the recording the hardware filter was applied with time constant of 10 seconds. The electrode locations were selected based on the 10–10 international standard EEG electrode placement with a reference electrode at Cz and a ground electrode at Fpz.

EEG signal processing was conducted using EEGLAB version 14_1_2b (Delorme and Makeig 2004) under Matlab R2022b (MathWorks, Natick, MA, USA). A high pass filter (1Hz) and commercial power supply noise reduction using cleanline plug-in were applied to the continuous waveforms. The segmented data was made with the following settings: zero-time point was the visuo-tactile stimulation onset (0 ms), segment range was −600 to 1200 ms. Infomax independent component analysis (ICA) (Comon 1994; Bell and Sejnowski 1995) was conducted on the segmented data. Based on the IC waveforms, artifact-contaminated trials were detected and discarded. The artifact detection criteria were identical to the previous study [5]. Using the artifact rejected datasets, another ICA was conducted. The dipole estimation was conducted on these ICs using dipfit2.3 (EEGLAB plug-in using FieldTrip toolbox functions (Oostenveld et al. 2011)).

Cortical activation-related ICs were selected from the all the ICs obtained by the second ICA, using ICLabel plugin (Pion-Tonachini et al. 2019) which automatically classifies the components into brain, muscle, eye and other. In this study, only the ICs classified as “brain” were included the further analysis.

The data were down-sampled to 128 Hz. Using the down-sampled data, scalegrams were calculated using Morse wavelet using Matlab function cwt() at 0–800 ms post-stimulus and 3–60 Hz to exclude high gamma frequency band.

C. Noise Data Measurement

To obtain the template noise data, EEG waveforms were recorded from one participant. The participant was not included in the datasets in the main experiment. The participant wore HMD and EEG-cap with 63 electrodes, in similar manner with the main experiment. The difference is the way to use fixation belt. In this template noise recording session, the fixation belt provided officially from the developer was attached to the participant’s head, in order to put the template noise in the recorded data (in the main experiment, belt touched only on the neck). Under this condition, the EEG electrodes

Mov Noise: neck movement noise, Line Noise: commercial power supply noise

must be contacted by the fixing belt, which made intense noise when the participant move own neck or head. The participants sat on the chair and continuously rotate the head for 1 minute. One stroke of head rotate was almost 2 s, which was previously trained using metronome. Furthermore, to obtain the commercial power line noise contaminated EEG data, all devices for using HMD were connected into power outlet. In the main experiment, the HMD and tracking camera were connected to the mobile battery for power supply without outlet in order to avoid contamination of the power line noise.

Signal processing of the obtained EEG data with template noise was almost identical to the main experiment.

D. Adding the Noises to the Test Signals

The various types of noise template data were segmented into 1-s epochs, then a Tukey window was applied (0.25 rise, 0.5 plateau, 0.25 fall). The segmented noise epochs were randomly selected, allowing overlapping selections, to match user-specified rate of the contaminated data (range 0-1). The length-matched noise data were re-scaled using user-specified re-scaling factor. The noise data were linearly added to the randomly selected segments of the test signal. The same process was repeated for the number of the types of noises.

E. Evaluation using support vector machine (SVM)

Evaluation of EEG quality was conducted by classification accuracy calculated by SVM. SVM was conducted using to binary classification of the stimulation pattern (spatially congruent/incongruent visuo-tactile stimulation). Spatially congruent stimulation pattern generally induces the illusory feeling of body ownership, whereas spatially incongruent stimulation pattern does not induce the illusory feeling. For the SVM classification, data from all the time-frequency window in the all brain ICs were used. Iteration number was 250. As a kernel function radial basis function was adopted. Scale parameter was automatically selected using heuristic method. Cross validation of the model was conducted by k-fold cross validation. The number of separation was 5. Based on the calculated accuracy values, the mean parameter of the normal distribution was evaluated.

III. Results

Champion data in binary classification of original data was observed in a participant No 16 (classification accuracy was 61.5 illustrated in Fig.2 and Table1). The averaged classification accuracy across all participants was 56.67 (SD = 1.98). After neck movement noise addition, the averaged classification accuracy across all participants was 52.75 (SD = 1.52). Additionally, commercial power supply noise added on the data, the averaged classification accuracy across all participants was 52.15 (SD = 1.36). Subtraction the accuracy in neck movement noise added datasets from original accuracy percentages revealed 3.9 (SD = 1.48) percent reduction by the noise addition in average. Subtraction the accuracy in neck movement and commercial power supply noise added datasets from the accuracy in neck movement noise added datasets revealed 0.6 (SD = 1.21) percent reduction by the noise addition in average.

IV. Discussion

In this study, we aimed to evaluate the impact of noise generally contaminated during VR experiment using HMD on scalp EEG. We calculated classification accuracy using SVM

for each individual person, in terms of stimulation pattern (spatially congruent/incongruent stimulation). As the results, we have revealed about 4 % reduction of classification accuracy rate in average. Especially, we observed an example of 8 % reduction (S12), which suggest that the neck movement noise has very intense impact on the EEG waveforms when we want to use the EEG spectrum power to predict any psychological event.

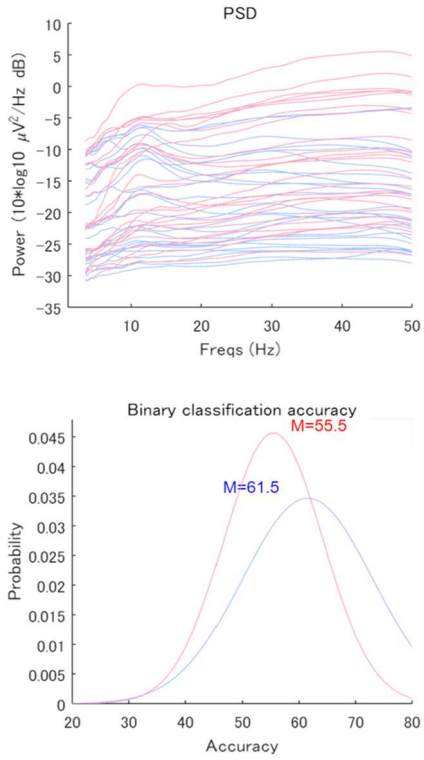

Fig. 2 Modulation of power spectrum density and binary classification accuracy by adding the neck movement noise on original EEG waveforms.
Top: Power spectrum density for each independent component, calculated by averaging ERSPs across all trials. Blue line: Original data. Red line: Noise added data. Bottom: Binary classification accuracy results. The unit of accuracy and Probability was percentage. PSD: Power spectrum density. Blue line: Original data. Red line: Noise added data

Although the neck movement noise has great impact on the EEG quality in terms of classification accuracy, an impact of the power supply noise, which was traditionally cared in psychophysiological research fields, was limited. Subtraction between with/without power supply noise conditions revealed less than 1% reduction of classification accuracy. For some participants, classification accuracy rate increased after power supply noise addition. These results suggested spectrum power of stationary wave at the high frequency range does not take important role when machine learning automatically separate the data. It seems that even if a stationary wave with little temporal fluctuation was added to the waveform for each condition, this did not significantly affect the difference in features between the conditions. Moreover, most of EEG components activated by any experimental stimulation related body in virtual reality environment were at the low frequency band, like alpha [2, 7, 8]. In addition, recent review on EEG study in VR also suggested that some studies demonstrated lower frequency band activities like alpha band can have significant role, while only one study has observed high frequency range activity like gamma band [9].

However, this does not suggest that we can ignore the power supply noise in any case. Some studies demonstrated gamma band oscillation could be an important role for motion recognition [10], motor control [11], and motion imagery [12]. It should be noted that we should evaluate the impact of noise for each experimental setting.

As limitations of this study, the accuracy of the 2-class classification using SVM is low. It should be caused by the abstractness of the 2-classes. In this study, we have tried to classify the EEG responses corresponding to spatial congruency of the visuo-tactile stimuli during the rubber hand illusion regarding body ownership, which can induce very highly cognitive process. Although, in the neuroscience with VR, the body recognition/ownership is very important theme, it is more useful to use simpler classification (e.g. right and left arm movement) for evaluation of noise contamination itself. In future study, we should choose more simplified classification.

Moreover, as an another limitation, we mention about the difference of indices between this study and traditional neuroscience and psychophysiological studies. In this study, classification accuracy was adopted to evaluate the noise impact, whereas traditional studies used a significant difference calculated by statistical test, for example, t-test. The results in this study does not have any direct impact on the traditional EEG studies which aimed at finding statistically significant differences. From the other perspective, usage of simple machine learning, SVM, is a limitation. Recently we could easily access any deep learning technique to classify the EEG data, many researchers tried to use deep learing for EEG data classification [13, 14]. In the case of EEG classification using deep learning, which automatically extracts feature values, it

seems that the results will dramatically change. In future, we should try to simulate the noise impact on various EEG classification methods.

ACKNOWLEDGMENT

Department of Communications, National Tsing Hua University, Hsinchu, Taiwan

***Abstract*—When building models for action recognition, 3D convolutional neural networks (CNNs) are commonly used. However, 3D CNNs also increase the model parameters significantly. We propose two methods, image segmentation and dynamic sampling learning to reduce network parameters and required memory access. Using image segmentation to keep the location of the action and remove the background of each image reduces the size of the feature map. Dynamic sampling learning allows the model to learn from low sampling rates without adding additional parameters, and to maintain performance while reducing the number of images. In order to implement the overall model in hardware for edge devices, we limit the kernel sizes of the 2D convolution layers and 3D convolution layers in the model to only 3x3 and 3x3x3 respectively. We perform experiments on HMDB51 [1] and UCF101 [2] datasets respectively with our proposed model. The accuracy of our proposed method achieve 7.2% and 5.9% reduction compared with DS-GRU2021 [3]. However, the number of parameters of our model is 30% fewer and execution speed x180 faster than DS-GRU2021 [3].**

***Index Terms*—Action Recognition, Deep Convolutional Networks, Real-time Computing, Dynamic Sampling Learning.**

I. Introduction

In recent years, convolutional neural networks(CNN) have been used in various application in computer vision, such as object detection, face recognition, and action recognition. However, the computing resources and memory units on the edge devices are limited. Traditional CNNs have high model computation and memory requirements, which makes it difficult to compute models on edge devices. Compared with common image recognition models, the action recognition model uses more complex 3D CNNs than 2D CNNs and the input of the model is increased to multiple images.

The current action recognition model uses three different strategies. The first one is to use all 2D CNNs in the model for computation [4]; the second one is to use all 3D CNNs in the model for computation [5]–[9]; and the last one is to combine these approaches to construct the model [10].

In our work, we focus on solving the problem of the large number of parameters and memory requirements of action recognition models. We propose two methods to reduce the memory used during model calculation, namely using image segmentation models on the network front-end and dynamic sampling learning. The first method involves using an image segmentation module on the front-end of the model to reduce the size of the feature map. The second method involves using dynamic sampling learning to reduce the number of images input to the model.

The rest of this paper is organized as follows. In Section II, we present the proposed approach to reduce the computation of 3D CNN by using eCNN modules and by image segmentation, and to reduce the number of input images to the model by using dynamic sampling rate. We also improve the hardware accelerator to allow the model to be computed efficiently. In Chapter III, we present the experimental results, and compare the proposed model with the results of other papers.

Our contribution in this thesis is as follows:

• We propose a hardware-friendly and less image based action recognition model.Our estimation indicates that the model only requires 2 images for each action, and the number of parameters is 5.11M, which is 30% less than [3].

• The accuracy of our proposed model is 65.1% for HMDB51 [1] and 89.6% for UCF101 [2] dataset. While these accuracies are lower than those achieved by Amin *et al.* [3], with a difference of 7.2% and 5.9% respectively, our model boasts a significantly faster execution speed, being x180 times faster.

II. Proposed Methods

A. Overall Scenario of Proposed Method

Our proposed action recognition model consists of four main components, as illustrated in Figure 1. The first component is an image segmentation module built on the eCNN [11] architecture. By employing image segmentation at the front end of the model, the subsequent 3D CNNs can focus on the action's location. This image segmentation process reduces the size of the feature image initially. The second component is a 2D CNN, which constructs a pathway to learn the appearance of an object and preserve the object's features after image segmentation. This step enhances the model's performance towards the end of the network. The third component comprises a 3D CNN that enables the model to learn temporal information between actions using the feature maps obtained from the previous image segmentation as input. The fourth component utilizes dynamic learning to facilitate self-learning within the model and improve its performance under varying sampling rates.

B. Video Down Sampling

Before proceeding with the identification process, we needed to convert the RGB video into RGB images. The

979-8-3503-0067-3/23/$31.00 ©2023 IEEE

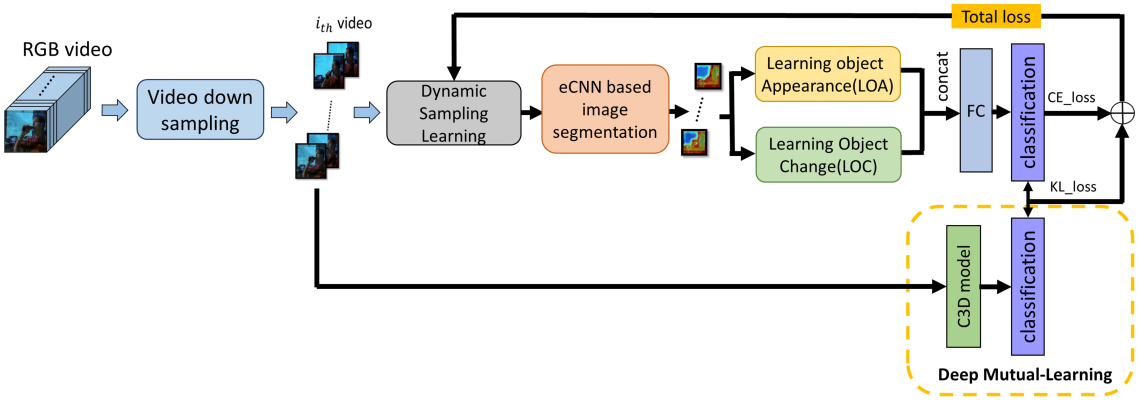

Fig. 1: Overview of the proposed architecture for video recognition system.

sampling rate for each video varied based on its length, with longer videos being sampled at larger intervals per frame. However, to maintain a sufficient amount of information for each video after sampling, we employed different sampling rates for each video, while ensuring that a minimum number of frames were sampled from each video.

C. Image segmentation based on eCNN

The image segmentation module can be broadly divided into two parts. The first part involves increasing the number of channels in the feature map. This is done to capture more spatial information. Specifically, when calculating the maximum pooling layer, the number of channels in the feature map is increased.

The second part consists of a stack of basic 2D eCNN modules. Each 2D eCNN basic block consists of two layers of 2D convolution. Furthermore, the kernel size of the convolutional layers in the 2D eCNN basic block is fixed at 3x3. This choice simplifies hardware calculations as the same method can be applied uniformly.

D. Dynamic Sampling Learning

Our work drew inspiration from the model proposed by Feichtenhofer *et al.* [12] and also took into account the experimental results presented by Wu *et al.* [13]. When evaluating the same action using the same model, we observed that certain actions performed better at lower sampling rates, while others performed better at higher sampling rates. This suggests that the model learns different performance characteristics for the same action at different sampling rates during the learning process.

Figure 2 illustrates the details of the dynamic sampling learning module. The process begins with an initial sampling interval, denoted as r_{curr}. Using this interval, images are sampled at regular intervals of r_{curr} from the processed video. These sampled images form a set called f_i. The model then processes these images and generates an estimation, from which a loss value is obtained.To determine the progress of learning, the obtained loss value is compared with the previous loss value. If the difference between the two values is less than the predetermined threshold, it indicates that the current model has already learned well at the current sampling interval. Consequently, the sampling interval for the next model to be learned is updated as $r_{next} = r_{curr} + 1$. This approach allows for adaptive adjustment of the sampling interval based on the model's learning progress.

E. Learning object Appearance(LOA)

To preserve the object information at the end of each frame after the image has been segmented, a separate pathway consisting of a 2D convolutional network is employed. This pathway is designed to prevent the previous spatial information from being influenced by the simultaneous learning of both temporal and spatial information within the 3D convolutional network.

By sending the segmented images as inputs to the pathway responsible for learning object appearance, the spatial information is retained and carried towards the backend of the network. This approach ensures that the spatial features of the objects are preserved and effectively learned within the model.

F. 3D based Short Sequence Action Module

The 3D-based Short Sequence Action Module is designed to enable the model to learn the temporal information between images using a network composed of 3D convolutional layers.

In the input section of this module, the output of the previous image segmentation module is stacked and then fed into the 3D convolution operation. By utilizing the image segmentation module at the front end of the network, we have successfully reduced the size of the feature image. This reduction in size not only saves memory but also reduces the computational requirements for 3D convolution within this module.

However, since the front end of the model utilizes 2D convolutional layers, the network has not yet learned temporal information. Therefore, this section of the module consists of a total of 6 stacked basic 3D blocks. Each 3D basic block comprises 2 layers of 3D convolution, 2 layers of batch normalization, and a final layer of ReLU activation.

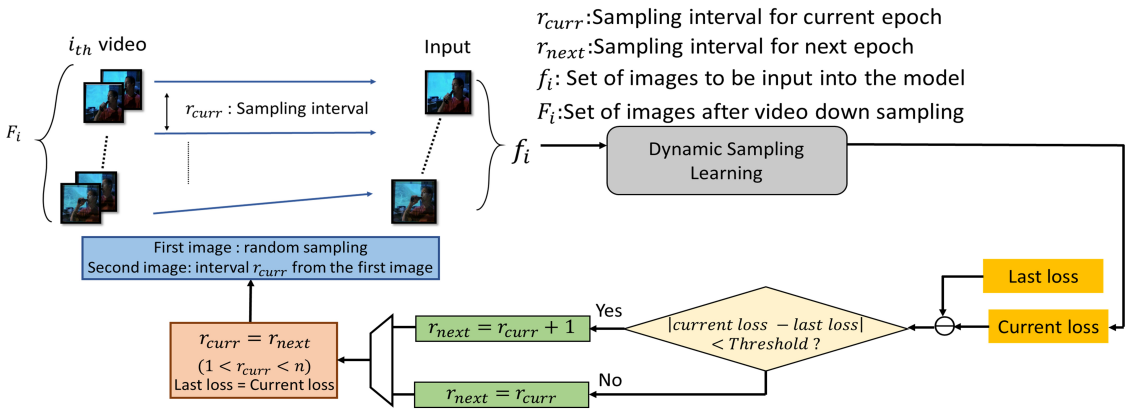

Fig. 2: Overall Framework for Dynamic Learning Sampling.

Additionally, the kernel sizes of the 3D convolution layers within the basic blocks are all set to 3x3x3.

G. Hardware Architecture

We have made improvements to the hardware architecture originally designed by Lin *et al.* [14] to support our action recognition model. Figure 3 illustrates the overall hardware architecture, which consists of three main components: the storage unit, the computing unit, and the SRAM controller.

The storage units include the Weight SRAM (WSRAM), which stores the model parameters, the Feature SRAM (FSRAM), which stores the input images for model calculations, the Fully Connected Layer SRAM (FCSRAM), which stores inputs for the fully connected layer, the Temporal SRAM (TSRAM), which temporarily stores the output after the image segmentation model has been computed, and the Output Reuse SRAM (ORSRAM), which temporarily stores the output to facilitate the calculation of the max-pooling layer.

The convolutional core module is used for performing 2D and 3D convolutional operations. It can process 64 input channels and generate 64 output channels simultaneously, with 9 processing elements (PEs) and stacks within each PE array. By matching the number of PEs with the input channels of the model and implementing a ring stream flow to reuse the feature map, the architecture reduces the need for additional storage units for each layer, resulting in more efficient computation and minimizing the storage requirements for partial sum calculations.

III. Experimental Results

A. Implement Details

The whole experiment was implemented and validated using the PyTorch framework [15]. During the model training phase, we relied on the experiments conducted by Kataoka *et al.* [16] and their corresponding results. These experiments demonstrated that models utilizing pre-training tend to outperform those trained from scratch. Consequently, our model incorporates the dataset proposed by Goyal *et al.* [17] for pre-training purposes.

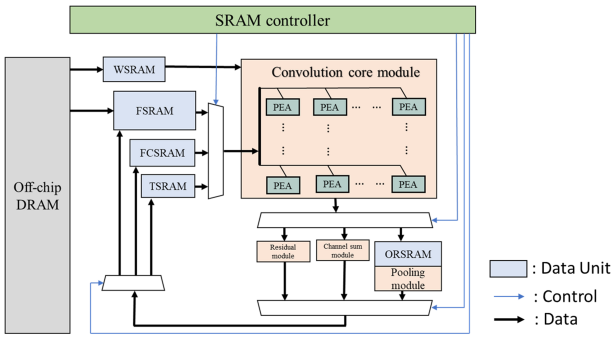

Fig. 3: Overview of the proposed architecture for action recognition accelerator.

B. Training & Testing Datasets

To pre-train our model, we utilize the Something-Something V1 dataset [17] dataset to pre-train our model. The estimated performance of the model is then evaluated using two other datasets: HMDB51 [1] and UCF101 [2].

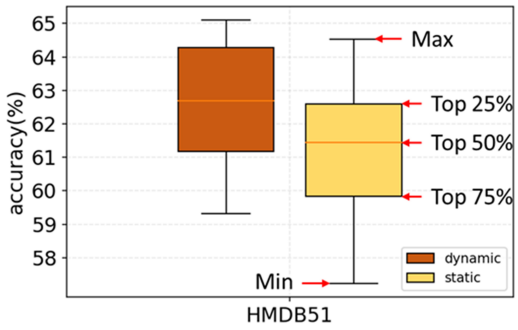

Fig. 4: Box plots on HMDB51 dataset using different training methods.

C. Ablation study

We employ two different approaches to train the model. The first approach involves training the model with a fixed

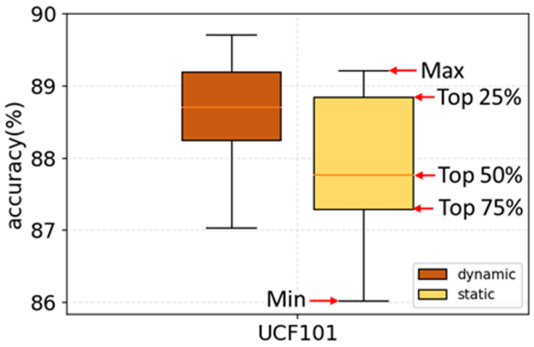

Fig. 5: Box plots on UCF101 dataset using different training methods.

sampling interval for each video, where we set the sampling interval to 5 in this experiment. The second approach is our proposed dynamic learning of the sampling rate, where the model adjusts the sampling interval based on the current situation. During the estimation, the sampling interval of the video is randomly changed. We conduct 30 experiments using these two training methods and present the results as box-plots in Figure 4, Figure 5 and Table I. Comparing the two methods, the dynamic learning of the sampling rate yields more centralized accuracy compared to the fixed method, indicating a more stable model. This suggests that the model trained with dynamic sampling exhibits improved consistency and reliability, as evidenced by the more concentrated results.

TABLE I: Testing accuracy on HMDB51 and UCF101 dataset using different training methods.

Data-set	Training method	mean	std	min	Q1 (top75%)	Q2 (top50%)	Q3 (top25%)	max
HMDB51	Dynamic (%)	62.58	0.018	59.32	61.17	62.68	64.28	65.11
	Fixed (%)	61.15	0.020	57.22	59.83	51.45	62.58	64.53
UCF 101	Dynamic (%)	88.64	0.007	87.03	88.24	88.7	89.14	89.6
	Fixed (%)	87.94	0.009	86.02	87.28	87.77	88.84	89.21

TABLE II: Pre-training + Mutual-learning(with C3D) on HMDB51 [1] dataset and UCF101 [2] dataset .

	HMDB51		UCF101	
Ratio (CE_loss/KL_loss)	C3D [5]	This work	C3D [5]	This work
Original	66.3%	62.5%	95.0%	89.1%
0.2/0.8	62.7%	63.4%	95.1%	89.2%
0.4/0.6	66.4%	63.7%	95.5%	89.1%
0.6/0.4	65.4%	62.6%	96.8%	89.4%
0.8/0.2	67.0%	65.1%	97.1%	89.6%

During the training process, we incorporate a method called Deep Mutual Learning, proposed by *et al.* [25], to enhance the learning of our model. This approach involves utilizing more than two models, including our own model and the C3D model proposed by Tran *et al.* [5]. We adjust the loss ratio between the models to optimize their learning performance. In our experiments, we tested four different loss scales on the two datasets, as presented in Table II. The results indicate that the best performance is achieved when the ratio between the Cross-Entropy (CE) loss and the Kullback-Leibler (KL) loss is set to 1:4.

D. Compare with other works

In this section, we evaluate our results on two datasets, HMDB51 and UCF101, using a GPU, in order to compare them with the results of other works. Our work stands out with the lowest number of parameters and computational cost among the works listed in Table III. Other works, such as Liu *et al.* [18], Tran *et al.* [6], Parmar *et al.* [19],Wu *et al.* [22], and Carrecira *et al.* [7] require larger model sizes and more computation, yet their accuracies on HMDB51 and UCF101 are lower compared to our work.

When compared with Amin *et al.* [3], our model surpasses their performance in terms of the number of parameters and speed, even though there is a slight decrease in accuracy, as demonstrated in Table III. Wu *et al.* [21] achieves the highest accuracy on UCF101 and the second-highest accuracy on HMDB51, but their parameter size is five times larger than our model.

IV. Conclusion

We have developed an action recognition model that addresses the issue of high memory requirements by integrating dynamic sampling learning and an image segmentation module at the front-end of the network. This approach enables us to reduce the size of feature images and the number of input images to the model. Additionally, our model exclusively utilizes RGB images as input, eliminating the need for optical flow images and significantly reducing pre-processing time, thereby achieving real-time performance. Notably, our model is capable of inference on our dedicated hardware accelerator.

Through our experimental results, we observed that employing dynamic sampling learning had a significant impact on the model's performance. The overall average accuracy and maximum accuracy were higher when using this method.

Ultimately, our proposed model achieves an accuracy of 65.1% for HMDB51 [1] and 89.6% for UCF101 [2] dataset. While these accuracy figures are 7.2% and 5.9% lower, respectively,compared to Amin *et al.* [3], our model offers significant advantages. We achieve a 30% reduction in the number of parameters, and the execution speed is 180 times faster.

Real-Time Processing for Weighted Pulse Decomposition of Photoplethysmography Signals Based on Interior Point Method in Wearable Devices for Hemodynamic State

Ting-Jui Wong and Pei-Yun Tsai

Department of Electrical Engineering,

National Central University, Taiwan

***Abstract* — Waveform decomposition technique can be applied to analyze photoplethysmography (PPG) signals from wearable devices for revealing the latent property of hemodynamic state. Solving for the component waves is considered as a constrained nonlinear optimization problem. The interior point method is used with a refined step size during line search. Exact derivatives in Hessian matrix and gradient are adopted in this work to acquire precise results. Inter-dependency and intra-dependency of the derivatives are exploited to reduce 93.7% computation complexity with a storage of only 62 ingredients. The block LDL decomposition with Bunch Kaufman pivoting strategy that takes advantage of symmetry property of Hessian matrix is employed to handle the linear equations described for the step size. Both single-precision and double-precision arithmetic are supported. From the experimental results, failure rate of 1.93% and one-cycle processing time of 0.1s are achieved by our program, which outperforms the commercial solver and the real-time processing requirement can be satisfied to demonstrate its applicability in the wearable devices.**

***Index Terms*—**waveform decomposition, interior point, line search, photoplethsymogram.

I. Introduction

Waveform decomposition technique is widely used in various applications, such as light detection and ranging (LiDAR) [1]-[3] and PPG signal analysis [4][5], to reveal the latent properties of the superimposed component waves. PPG signals derived from low-cost optical module equipped in all kinds of wearable devices to sense the blood volume change are commonly adopted for estimation of pulse wave velocity [6] and blood pressure [7]. With the waveform decomposition technique, the PPG pulse can be decomposed into the forward waves and the reflected waves which are mainly caused by the juncture between thoracic and abdominal aorta as well as the juncture between abdominal aorta and common iliac arteries. As a result, further intrinsic information of hemodynamic state can be observed.

Waveform decomposition can be considered as a constrained nonlinear optimization problem. In [1], the modified Levenberg-Marquardt (LM) method is used while Gauss-Newton algorithm is utilized in [2]. The interior point algorithms with boundary constraints derived from PPG features are adopted in [4] and [5]. All of these take into consideration Gaussian function as the basis of component waves because its morphology resembles the pulsatile wave. Although software packages have been implemented [8][9], we aim to develop the waveform decomposition technique to fulfill real-time processing requirements with both single-precision and double-precision arithmetic so as to support health monitoring in the wearable devices.

Usually, one PPG cardiac cycle can be decomposed into five Gaussian component waves, three in systole and two in diastole. Solving the optimization problem involves the iterative procedure. Thus, the precision effect influences either the processing time or the accuracy. We employ the exact derivatives of the Hessian matrix and the gradient vector during line search. Inter-dependency and intra-dependency are exploited to accelerate the computation. Only 62 ingredients are reserved. The required partial derivatives are generated by their paired products and 93.7% floating-point operations (flops) in raster scan order can be reduced. The strategy of refined step size for better adjustment is also proposed. We also take advantage of the symmetry of the Hessian matrix by using LDL decomposition to calculate the step size and to deal with the symmetric indefinite issue. From simulation results, more PPG pulses are successfully decomposed with fast processing time by our algorithm than by a Matlab generic solver. Also, high correlation exists between decomposed component waves from the synchronized finger and wrist PPG pulses.

II. System Model of Waveform Decomposition

Waveform decomposition can be described as an optimization problem that aims to minimize an objective function $f_{\mathrm{WMSE}}: \mathbb{R}^R \to \mathbb{R}$, where $\mathbf{x} \in \mathbb{R}^R$ denotes the vector of optimization variables with the inequality constraints $\boldsymbol{g}: \mathbb{R}^R \to \mathbb{R}^M$ as follows,

$$\min_{\mathbf{x}} f_{\mathrm{WMSE}}(\mathbf{x}) \tag{1}$$

$$\text{s.t. } \boldsymbol{g}(\mathbf{x}) \leq \mathbf{0} \tag{2}$$

Without loss of generality, the objective function is defined as the weighted mean square error between the normalized PPG pulse $p(n)$ and the fitting function $f(n, \mathbf{x})$.

$$f_{\mathrm{WMSE}}(\mathbf{x}) = \frac{1}{N} \times \sum_{n=1}^{N} (w(n) \times [p(n) - f(n, \mathbf{x})]^2) \tag{3}$$

where N is the length of one cardiac cycle, $w(n)$ denotes the weight. The fitting function $f(n, \mathbf{x})$ can be further described by the summation of Gaussian component waves,

$$f(n, \mathbf{x}) = \sum_{j=1}^{5} f_j\left(n, \mathbf{x}_j\right) \tag{4}$$

979-8-3503-0067-3/23/$31.00 ©2023 IEEE

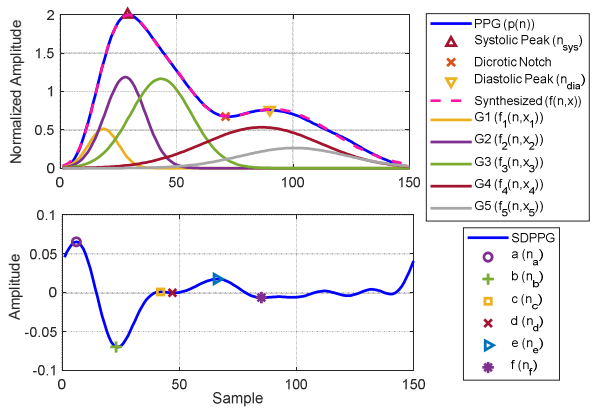

Fig. 1 Features from PPG as well as SDPPG and five component waves from waveform decomposition.

Table I: Boundary constraints of variables $[\alpha_j\ \beta_j\ \gamma_j]^T$, where $U_{b_{\beta 4}} = n_f/3 + 2N/3$.

	α_j		β_j		γ_j	
	L_{α_j}	U_{α_j}	L_{β_j}	U_{β_j}	L_{γ_j}	U_{γ_j}
$j=1$	0	A_b	n_a	n_b	0	$n_b/3$
$j=2$	0	A_{sys}	n_a	n_c	$n_a/3$	$n_d/3$
$j=3$	0	$0.8A_{sys}$	n_b	n_{d_n}	$n_b/3$	$n_{d_n}/3$
$j=4$	0	A_{dia}	n_{f_n}	U_{β_4}	0	$N/3$
$j=5$	0	A_{dia}	n_f	N	0	$N/3$

with $\mathbf{x} = [\mathbf{x}_1^T \quad \dots \quad \mathbf{x}_5^T]^T$ and

$$f_j(n, \mathbf{x}_j) = \alpha_j exp\left(-\frac{(n-\beta_j)^2}{2\gamma_j^2}\right), \tag{5}$$

where $\mathbf{x}_j = [\alpha_j\ \beta_j\ \gamma_j]^T$; α_j is the amplitude gain; β_j is the peak position; γ_j is the wave width of the jth Gaussian component wave (Gj).

From [5], the boundary constraints $\boldsymbol{g}(\mathbf{x})$ are given in Table I, where n_ω represents the position of feature ω ; A_ω indicates the PPG amplitude of feature ω; L_y and U_y are the lower bound and upper bound of variable y with $L_y \le y \le U_y$ and $y \in \{\alpha_j, \beta_j, \gamma_j\}$. The features of systolic peak (sys) and diastolic peak (dia) are local maxima of PPG while feature points a, b, c, d, e, and f are the extrema extracted from the second-derivative PPG (SDPPG) as shown in Fig. 1. Point d_n (f_n) is either zero-crossing point if it exists or middle point between points d (f) and e. Besides 30 constraints in Table I, four additional constraints are

$$\beta_j < \beta_{j+1} \qquad \text{for } j = 1, \dots, 4. \tag{6}$$

for delineating the ordering of peak positions. Hence, $R = 15$, $M = 34$ in the optimization problem. In addition, the weight is chosen to distinguish the informative portion of the PPG pulse between n_a and n_f, which is given by

$$w(n) = \begin{cases} 5 & n = n_a, \dots, n_f \\ 1 & else \end{cases}.$$

III. Waveform Decomposition Based on Interior Point Method

A. Interior Point Method (IPM)

Interior point methods can solve constrained optimization problems. The inequality constraints are transformed into equality constraints by introducing a vector of slack variables $\mathbf{s} = [s_1 \quad \cdots \quad s_M]^T$ as follows.

$$\min_{\mathbf{x},\mathbf{s}} \boldsymbol{\varphi}_\mu(\mathbf{x}, \mathbf{s})$$

$$\boldsymbol{\varphi}_\mu(\mathbf{x}, \mathbf{s}) \equiv f_{\text{WMSE}}(\mathbf{x}) - \mu \textstyle\sum_m \ln(s_m) \tag{7}$$

$$\text{s.t. } \boldsymbol{g}(\mathbf{x}) + \mathbf{s} = \mathbf{0}. \tag{8}$$

A logarithmic barrier term is included in the objective function to create barrier near the boundary of the feasible region. Value μ denotes the positive barrier parameter for each suboptimal problem and decreases gradually in the iterative procedure by a factor θ_μ.

$$\mu \leftarrow \theta_\mu \times \mu. \tag{9}$$

Hence, the effect of the barrier term diminishes because value μ converges to zero gradually.

The Lagrangian function $\boldsymbol{\mathcal{L}}$ is formed for solving the constrained optimization problem as follows.

$$\boldsymbol{\mathcal{L}}(\mathbf{x}, \mathbf{s}, \boldsymbol{\lambda}_g; \mu) = f_{\text{WMSE}}(\mathbf{x}) - \mu \sum_m \ln(s_m) + \boldsymbol{\lambda}_g^T(\boldsymbol{g}(\mathbf{x}) + \mathbf{s}) \tag{10}$$

where $\boldsymbol{\lambda}_g \in \mathbb{R}^M$ denotes the vector of Lagrange multipliers with nonnegative elements. Therefore, the minimum occurs when the partial derivatives of the Lagrangian function are zero. In other words, $\boldsymbol{\nabla \mathcal{L}} = \mathbf{0}$. Solution of the nonlinear equations can be found by the Newton's method. Let the step direction be $\mathbf{d} \equiv \left[\mathbf{d}_\mathbf{x}^T\ \mathbf{d}_\mathbf{s}^T\ \mathbf{d}_{\boldsymbol{\lambda}_g}^T\right]^T$ with $\mathbf{d}_\mathbf{x} \in \mathbb{R}^R$, $\mathbf{d}_\mathbf{s} \in \mathbb{R}^M$, and $\mathbf{d}_{\boldsymbol{\lambda}_g} \in \mathbb{R}^M$. Applying Newton's method, we have

$$(\boldsymbol{\nabla^2 \mathcal{L}})\mathbf{d} = -\boldsymbol{\nabla \mathcal{L}} \tag{11}$$

where $\boldsymbol{\nabla^2 \mathcal{L}}$ and $\boldsymbol{\nabla \mathcal{L}}$ denote the Hessian matrix and gradient of $\boldsymbol{\mathcal{L}}$.

To keep the variables in the feasible region, the maximal step size $\alpha_x^{\max}$, $\alpha_s^{\max}$, $\alpha_\lambda^{\max}$ must be constrained [9],

$$\alpha_x^{max} = \max\{\alpha \in (0, 1]: \tau(\mathbf{L} - \mathbf{x}) \le \alpha \mathbf{d}_\mathbf{x} \le \tau(\mathbf{U} - \mathbf{x})\} \tag{12}$$

$$\alpha_s^{max} = \max\{\alpha \in (0, 1]: -\tau \mathbf{s} \le \alpha \mathbf{d}_\mathbf{s}\} \tag{13}$$

$$\alpha_\lambda^{\max} = \max\left\{\alpha \in (0, 1]: -\tau \boldsymbol{\lambda}_g \le \alpha \mathbf{d}_{\lambda_g}\right\} \tag{14}$$

$$\alpha_z^{\max} = \min(\alpha_x^{max}, \alpha_s^{max}) \tag{15}$$

where $\mathbf{L}$ and $\mathbf{U}$ represent vectors of lower bounds and upper bounds of $\mathbf{x}$ in Table I; $\tau \in (0, 1)$ is a parameter defined for the fraction to the boundary. The variables are then updated along the step direction in the iterative procedure,

$$\mathbf{x} \leftarrow \mathbf{x} + \alpha_P \alpha_z^{\max} \mathbf{d}_\mathbf{x}, \tag{16}$$

$$\boldsymbol{\lambda}_g \leftarrow \boldsymbol{\lambda}_g + \alpha_P \alpha_\lambda^{\max} \mathbf{d}_{\boldsymbol{\lambda}_g}, \tag{17}$$

$$\mathbf{s} = -\boldsymbol{g}(\mathbf{x}). \tag{18}$$

In addition, we propose to include the ratio $\alpha_P \in \{1/P, 2/P, 3/P, \dots, P/P\}$ to refine the step size during line search, which is selected among the set according to the smallest value of $\varphi_\mu(\mathbf{x}, \mathbf{s})$ in (7).

As a result, the interior point method contains two loops. In the outer loop, the barrier parameter μ changes to define the suboptimal problem while in the inner loop, the solutions $\mathbf{x}$, $\mathbf{s}$ and $\boldsymbol{\lambda}_g$ for a given barrier parameter μ are calculated.

B. Methods for Solving Linear Equations

Algorithm 1 Interior Point Method for WPD

Input: initial values $\mathbf{x_0}$, lower bound $\mathbf{L}$ and upper bound $\mathbf{U}$
Output: variables of Gaussian component waves $\mathbf{x}$
Initialization: $\mu = \mu_0,\ i_1 = 1,\ \mathbf{x} = \mathbf{x}_0$

```
while i1 ≤ I1
    update μ by (9), i2 = 1
    while i2 ≤ I2
        Update s by (18)
        Form ∇ℒ and ∇²ℒ
        Solve linear equations (11) by LDL or CG
        Determine α_T, α_z^max, α_λ^max by (12)-(15)
        Update x by (16)
        Update λ_g by (17)
        if early termination is true
            return x
        endif
        i2 ← i2 + 1
    end while
    i1 ← i1 + 1
end while
return x
```

Let $\mathbf{A} = \nabla^2\mathcal{L}$ and $\mathbf{b} = -\nabla\mathcal{L}$. There are several methods that can be used for solving linear equation of $\mathbf{Ad} = \mathbf{b}$ in (11). The LU, LDL, and QR decomposition approaches are categorized as direct methods while conjugate gradient (CG) and preconditioned CG are iterative methods [10]. The direct method has the advantage of the time complexity while the iterative method such as CG consumes less memory. Note that the Hessian matrix $\mathbf{A}(= \nabla^2\mathcal{L})$ is symmetric. Factorizing matrix $\mathbf{A}$ into $\mathbf{LDL^T}$ can exploit the symmetry property and thus LDL decomposition has lower computation complexity than other direct methods [11].

Block LDL with Bunch Kaufman pivoting strategy [12] can decompose a square matrix that is symmetric indefinite into a lower triangular matrix $\mathbf{L}$, a block diagonal matrix $\mathbf{D}$, and a permutation matrix $\mathbf{P}$, namely

$$\mathbf{A} = \mathbf{P}^T\mathbf{L}\mathbf{D}\mathbf{L}^T\mathbf{P}. \tag{19}$$

Let

$$\mathbf{L}\mathbf{y_1} = \mathbf{P}\mathbf{b},\quad \mathbf{D}\mathbf{y_2} = \boldsymbol{y_1},\quad \mathbf{L}^T\mathbf{y_3} = \boldsymbol{y_2}, \tag{20}$$

$$\mathbf{P}\mathbf{d} = \mathbf{y_3}. \tag{21}$$

The desired vector $\mathbf{d}$ can be derived by forward and backward substitutions and permutation as described in (20) and (21), respectively.

The iterative CG method is suitable for solving large and sparse systems of linear equations. In the implementation, the maximum numbers of iterations are set as 5 and 25 times the dimension of Hessian matrix for double-precision and single-precision arithmetic, respectively. The residual will be updated and checked for every step. The iterative procedure will be terminated if the residual is smaller than or equal to $\Delta(= 10^{-10})$ to ensure that the result is a suitable solution for the equations. The complete algorithm is given in Algorithm 1 with $I_1 = 100,\ I_2 = 20$.

C. *Calculations for Exact Hessian and Gradient*

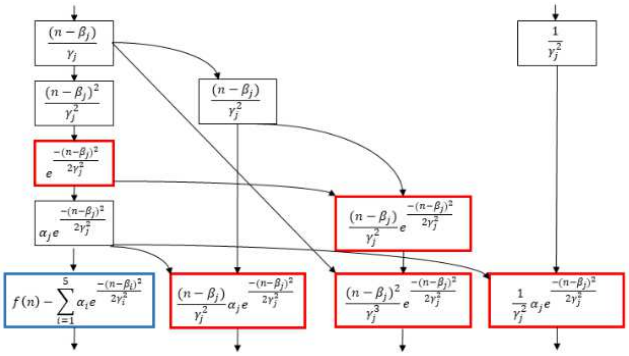

Fig. 2 Data flow graph of computations in Hessian matrix.

The Hessian matrix and gradient vector contain derivatives of the Lagrangian function. Although the finite difference can be used to approximate the derivatives in some software package, the exact derivatives are adopted in this work to acquire precise results during line search. However, the computation time of decomposing one PPG pulse is too long to satisfy real-time processing constraint if the derivatives are calculated intuitively in raster scan order. Since the derivative of an exponential function still consists of the original exponential function, the calculations for Hessian matrix and gradient vector can be simplified by exploiting dependency. Two types of dependency, intra-dependency and inter-dependency, are utilized. Consider two terms in Hessian matrix,

$$\frac{\partial}{\partial\beta_k}\left(\frac{\partial}{\partial\alpha_j}\right)\mathcal{L} = \frac{2}{N}\sum_n w(n)\left(e^{\frac{-(n-\beta_j)^2}{2\gamma_j{}^2}}\right)\left(\alpha_k e^{\frac{-(n-\beta_k)^2}{2\gamma_k{}^2}}\right)\left(\frac{n-\beta_k}{\gamma_k^2}\right), \tag{22}$$

$$\frac{\partial}{\partial\alpha_k}\left(\frac{\partial}{\partial\alpha_j}\right)\mathcal{L} = \frac{2}{N}\sum_n w(n)\left(e^{\frac{-(n-\beta_j)^2}{2\gamma_j{}^2}}\right)\left(e^{\frac{-(n-\beta_k)^2}{2\gamma_k{}^2}}\right). \tag{23}$$

The intra-dependency of $\frac{n-\beta_k}{\gamma_k^2}$ in (22) and the inter-dependency between (22) and (23) can be seen. The data flow graph is partly depicted to reveal the dependency as shown in Fig. 2. The result of the successor related with intra-dependency in the flow graph overwrites the result of the predecessor in the same storage to keep minimal storage size while the results associated with inter-dependency can be fetched from these storages to reduce computations. Therefore, for all j, k, a total of 62 ingredients are saved, indicated by the red and blue blocks, and the partial derivatives in Hessian matrix can be formed by their paired products. For each n value, only 245 flops and 5 exponential functions are executed as opposed to 3905 flops in raster scan order, 93.7% flops are eliminated in the multi-Gaussian fitting model.

IV. Simulation Results

The program of weighted pulse decomposition is realized by C without multi-threading. The simulations and measurements are first carried out with Intel CPU i7-6700, DDR4 32GB, under Ubuntu 18.04.6 for comparison with the Matlab solver.

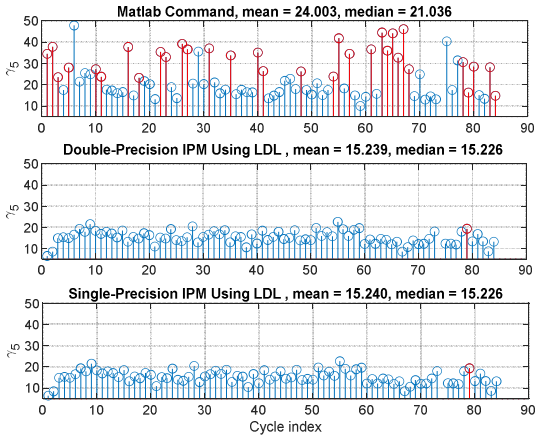

Fig. 3 Decomposition results of wave width of $G5$ from different approaches.

Table I Processing time when $\theta_\mu = 0.8$.

Case Setting	Case 1 CG $P = 16$	Case 2 LDL $P = 16$	Case 3 CG $P = 16$	Case 4 LDL $P = 16$	Case 5 LDL $P = 4$
SP	12.31s	1.00s	11.50s	0.24s	0.10s
DP	2.80s	1.87s	1.29s	0.36s	0.12s

The settings of the compiler flags -std=c99, -lm, -O3 are used with GCC 7.5.0.

In a one-minute PPG sequence, there are several tens of cardiac cycles. Usually, the morphology of PPG pulses and the component waves are slowly time-varying in stationary condition of the measurement conducted on a subject in a seated position. The signal quality index (SQI) of waveform decomposition is assessed by mean squared error, set to 2×10^{-3}, between $p(n)$ and $f(n, \mathbf{x})$. Fig. 3 shows the decomposition results of the width of $G5$, which plays an important role of the strongly-reflected diastolic wave, by Matlab solver (fmincon), double-precision and single-precision IPM using LDL from top to bottom respectively when $P = 16$. If the decomposed result fails to pass the SQI assessment, it is indicated by the red color. It is clear that our IPM program can generate stable decomposed component waves. In addition, both the single-precision arithmetic and double-precision arithmetic produce quite similar results. Only insignificant difference can be seen in their mean values.

Using different approaches to solve linear equations might generate different floating-point results. Usually, CG is sensitive to arithmetic precision and may need more iterations or compensations in order to suppress round-off errors for deriving small residual of the linear equations. Although the difference of the results obtained from CG and LDL is almost negligible when double-precision (DP) arithmetic is used, sometimes, apparent difference appears in some cases if single-precision (SP) arithmetic is employed. Table I lists the processing time, which is measured by the average of processing the weighted pulse decomposition problem using single and double precision arithmetic, respectively, for ten times. The intuitive computation in raster-scan order is adopted in Case 1 and Case 2. The improvement by exploiting intra-dependency and inter-dependency is shown in Case 3 and Case 4. In Case 5, the processing time is further reduced if operations such as schur complement and swap are implemented by taking advantage of the symmetric property for LDL. Besides, P is set to 4 for the refinement ratio α_P in (16) and (17). Thus, the effective of the proposed strategy is demonstrated. In addition, the processing time of the Matlab solver is about 0.15s. The program is then run on Raspberry Pi 4 Model B with ARM Cortex A72 processor. The processing times corresponding to DP and SP are listed in Table II with LDL for $P = 4$ and $P = 2$. Since one PPG cycle can be processed within 0.10s on Intel CPU or 0.24s on ARM for P=4, the real-time processing criterion can be satisfied. Furthermore, block LDL is a better approach for solving waveform decomposition owing to lower computation complexity, lower processing time, higher accuracy compared to the CG method if both single precision and double precision arithmetic operations are considered.

Table II Processing time on Raspberry Pi 4 Model B.

	DP		SP	
	mean	median	mean	median
P=4	0.31s	0.3s	0.24s	0.23s
P=2	0.256s	0.25s	0.198s	0.19s

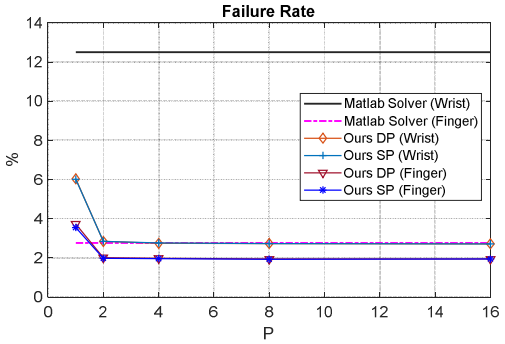

Fig. 4 Unqualified PPG cycles of different settings.

We then use the LDL-based IPM program to process the data set with 21441 finger PPG cycles and 20370 wrist PPG cycles from 60 persons. Fig. 4 shows the failure rate of unqualified decomposition results assessed by SQI versus various setting of P. Default setting is used for Matlab solver. The introduction of refined step size helps to achieve better adjustment of the variables to the barrier problem in (10). The effect of α_P in (16) and (17) during line search is verified. Usually the morphology of wrist PPG pulses is less recognizable than that of finger PPG pulses and thus more unqualified cycles are generated. However, when $P \geq 2$, our program shows a lower failure rate compared to the commercial solver, especially for wrist PPG. Table III provides the correlations of peak position and wave width from component waves $G3$, $G4$, $G5$. The correlations of $G1$ and $G2$ between writs PPG pulse and finger PPG pulse are lower than the values listed in the Table. There are 342 recordings from 60 subjects. The medians of the feature values from the synchronized and SQI-qualified finger and wrist PPG cycles of one-minute sequence are calculated and their correlation coefficients are examined. We can see that high correlation coefficients exist between the component waves of finger and

wrist PPG signals that are processed by the weighted waveform decomposition algorithm. Hence, the latent property of PPG pulse is acquired with consistency to a certain degree.

Table III Comparison of correlation coefficient (C.C.) of the decomposed component waves $G3$, $G4$, $G5$ between wrist and finger PPG cycles.

Feature	This work SP ($P = 4$)	This work DP ($P = 4$)	Matlab
Peak Position β_3	0.561	0.562	0.569
Peak Position β_4	0.679	0.679	0.658
Peak Position β_5	0.908	0.908	0.920
Wave Width γ_3	0.797	0.797	0.819
Wave Width γ_4	0.857	0.857	0.837
Wave Width γ_5	0.906	0.906	0.899

V. Conclusion

The weighted pulse decomposition of PPG signals solved by interior point method using exact derivatives is developed for wearable devices. The introduction of step refinement helps to improve the failure rate. The inter-dependency and intra-dependency in Hessian matrix and gradient are exploited to reduce 93.7% flops for partial derivatives of Gaussian-related function. Only 62 ingredients are reserved in the look-up table. The symmetry property of Hessian matrix is also utilized for schur complement and swap in LDL decomposition. From the experimental results, our program achieves better weighted pulse decomposition results of lower failure rate and less processing time compared to the commercial generic solver. In addition, both single-precision and double-precision arithmetic operations are supported for applications in wearable devices.

***Abstract*—Multi-cell cooperation is an effective means to improve service quality to cellular users. Existing work primarily focuses on interference cancellation using all the degrees of freedom (DoF). This leads to low service quality for some users with poor channel quality to its serving base station. This work investigates the multi-cell beamforming design for simultaneously enhancing the downlink signal strength and mitigating interference. We first consider the ideal case when perfect channel state information (CSI) is available for determining the beamforming vectors and then extend to the case of imperfect CSI. For both cases, the beamforming optimization problems are non-convex. Assuming perfect CSI, we obtain the optimal joint transmit (JT) beamforming vectors based on the uplink-downlink duality. In the presence of unknown CSI errors, we use the semidefinite relaxation (SDR) with Bernstein-type inequality to derive the robust JT beamforming. Numerical results are presented to evaluate the performance of the proposed schemes.**

***Index Terms*—Imperfect CSI, joint transmission, multi-input and multi-output (MIMO), quality-of-service (QoS), robust beamforming, and semidefinite relaxation (SDR).**

I. Introduction

Multi-cell cooperation is a practical approach to enhance the service quality to subscribers in the cellular network. Through the coordination across multiple base stations (BSs) in different cells, a large virtual antenna array can be formed to increase the spatial degree of freedom (DoF), which may be used to enhance signal power by sending the same data to user equipment (UE), known as the joint transmission (JT). Alternatively, it can be used to mitigate interference by coordinated beamforming (CB). The increased DoF of multi-cell cooperation permits a flexible and robust design of multi-cell beamforming schemes that perform JT while simultaneously alleviating undesired interference, which is this work's objective.

In the literature, several works have explored multi-cell beamforming design with different objectives. As the single-cell counterpart, the summed throughput is a common design objective for multi-cell beamforming design [1]. Since it is challenging to solve the downlink (DL) throughput maximization problem directly, it is shown in [1] that reformulating the beamforming design as an uplink (UL) dual problem allows a more solvable form and the solution of the dual problem delivers the same summed throughput as the DL problem. Such a UL-DL dual relation has long been used to facilitate beamforming design in multiple-input multiple-output (MIMO) systems, such as the early work [2] for the single-cell MIMO system, and more recent work [3] for the cell-free MIMO system. The UL-DL duality has also been used to minimize the total transmit power required to meet a prescribed quality-of-service (QoS) constraint, namely a target signal-to-interference-plus-noise ratio (SINR) in [4] assuming perfect CSI and in [5], [6] considering CSI errors. Again, they assume a single serving BS per UE [4]–[7] and use all the DoF for interference mitigation. Another type of beamforming design considers fairness, as in [8] that jointly designs the transmit beamforming across multiple BSs to maximize the worst SINR among all the served UEs. Such a max-min formulation can also be tackled through the UL-DL duality. Unlike aforementioned works that use instantaneous CSI to design the beamforming, long-term CSI in terms of channel correlation matrices is adopted in [8] with the assumption of ideal CSI. Another popular method for solving the beamforming design problem is to linearize non-convex SINR expressions through the semi-definite relaxation (SDR) [7], [9], which provides a convex approximation to the non-convex optimization problem without closed-form solution. In contrast, the UL-DL duality is established based on the Lagrange duality that provides a closed-form solution for the optimal beamforming vectors.

To fully leverage the benefit of multi-cell cooperation, this work explores the optimal JT beamforming at DL, where several BSs are grouped into a cluster and transmit DL data to the same UE simultaneously. This generalizes the existing work with the cluster size of one and can be implemented using the control signaling defined in the standard, such as 3GPP Release 16 [10]. This way, multiple DL data streams can be transmitted simultaneously to different UEs to increase spectral efficiency. We aim to minimize the total transmit power while satisfying a target SINR as in [4]–[7] for CB. Unlike CB, our problem is more complicated because the transmit beamforming needs to maximize the summed signal power at the intended UE and suppress the interference to the other UEs, provided with the increased DoF via multi-cell cooperation. We show that the UL-DL duality can still be applied to obtain the optimal JT beamforming when global CSI is perfect. In practice, the backhaul links for CSI exchange have limited capacity, and thus the CSI exchanged across the

979-8-3503-0067-3/23/$31.00 ©2023 IEEE

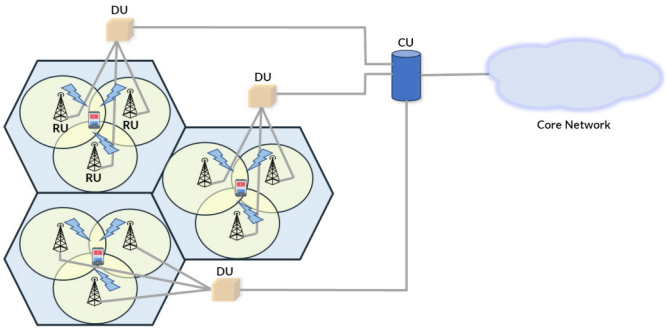

Fig. 1. Illustration of joint transmission in a multi-cell network.

cooperating BSs within the cluster is not perfect. The second part of this work addresses the optimal JT beamforming problem with imperfect CSI by extending [5] that considers the single-cell scenario. We demonstrate the significant gain of the optimal JT beamforming compared with the traditional non-JT beamforming and the zero-forcing (ZF) based beamforming through simulation results.

The remainder of this paper is organized as follows. Sec. II explains the system model. Sec. III presents the optimal JT beamforming design with perfect and imperfect CSI, respectively. Simulation results are shown in Sec. IV. Concluding remarks are given in Sec. V.

II. System Model

Consider a multi-cell network with multiple BSs deployed in a geographic area. Following the virtualized radio access network (vRAN) structure in 5G [11], a BS is split into different functional blocks, namely, the radio unit (RU) handling the RF transmission and reception, the distributed unit (DU) that carries out baseband signal processing, and the central unit (CU) performing the higher-layer protocols. Without loss of generality, one CU is deployed in the considered area, which is virtually partitioned into a set of cells denoted as $\mathcal{N}_c = \{\mathcal{C}_1, \cdots, \mathcal{C}_{N_c}\}$, each with N_b RUs connected to one DU via fronthaul links. The DU collects CSI from the RUs within the same cell and designs the DL beamforming. In this work, the term RU and BS will be used interchangeably. Each BS has N_t antennas, and each user equipment (UE) has a single antenna.

For the i-th cell, denote $\mathcal{C}_i = \{\text{BS}_{ib}\}_{b=1}^{N_b}$ the set of BSs connected to the same DU for $i = 1, \cdots, N_c$ and $\mathcal{U}_i = \{\text{UE}_{iu}\}_{u=1}^{|\mathcal{U}_i|}$ the set of UEs within the coverage area of the i-th cell. Considering the imperfect CSI, the true channel vector between BS_{ib} and UE_{iu} is modeled as

$$\mathbf{h}_{ib,iu} = \tilde{\mathbf{h}}_{ib,iu} + \mathbf{e}_{ib,iu} \tag{1}$$

where $\tilde{\mathbf{h}}_{ib,iu} \in \mathbb{C}^{N_t}$ is the estimated channel vector, and $\mathbf{e}_{ib,iu}$ represents the CSI error, which is assumed to be a complex Gaussian random vector with zero mean and the covariance matrix $\mathbf{Q}_{ib,iu} = \epsilon_{ib,iu}^2 \mathbf{I}_{N_t}$ where $\epsilon_{ib,iu}^2$ is referred to as the error radius. Then we can express the CSI error vector as

$$\mathbf{e}_{ib,iu} = \mathbf{Q}_{ib,iu}^{1/2} \mathbf{v}_{ib,iu} \tag{2}$$

where $\mathbf{v}_{ib,iu}$ is a normalized complex random vector with zero mean and the covariance matrix $\mathbf{I}_{N_t}$.

For simplicity, we assume that a cluster consists of all the BSs within the same cell, i.e., BSs in each cluster are coordinated by one dedicated DU. In the JT mode, all the BSs in the cluster send the same signal to the intended UE. The received signal at UE_{iu} is

$$y_{iu} = \sum_{b\in\mathcal{C}_i} \mathbf{h}_{ib,iu}^H \mathbf{w}_{ib,iu} s_{iu} + \sum_{b\in\mathcal{C}_i} \sum_{v\in\mathcal{U}_i\setminus u} \mathbf{h}_{ib,iu}^H \mathbf{w}_{ib,iv} s_{iv} + \sum_{\mathcal{C}_j\in\mathcal{N}_c\setminus\mathcal{C}_i} \sum_{b'\in\mathcal{C}_j} \sum_{v'\in\mathcal{U}_j} \mathbf{h}_{jb',iu}^H \mathbf{w}_{jb',jv'} s_{jv'} + z_{iu} \tag{3}$$

where s_{iu}, $\mathbf{w}_{iu} \in \mathbb{C}^{N_t}$, and $z_{iu} \sim N(0, \sigma^2)$ represent the DL signal, the transmit beamforming vector, and additive white Gaussian noise (AWGN) associated with UE_{iu}, respectively. The first term on the right-hand side is the collection of the intended signal for UE_{iu}, the second term is the intra-cell interference (Intra-CI), and the last term corresponds to the inter-cell interference (Inter-CI). Assuming the signal energy is normalized to one, the signal-to-interference-plus-noise ratio (SINR) of UE_{iu} based on true CSI is given by

$$\text{SINR}_{iu}(\mathbf{h}) = \frac{\sum_{b\in\mathcal{C}_i} |\mathbf{h}_{ib,iu}^H \mathbf{w}_{ib,iu}|^2}{I_{\text{Intra}} + I_{\text{Inter}} + \sigma^2} \tag{4}$$

where

$$I_{\text{Intra}} = \sum_{b\in\mathcal{C}_i} \sum_{v\in\mathcal{U}_i\setminus u} |\mathbf{h}_{ib,iu}^H \mathbf{w}_{ib,iv}|^2$$
$$I_{\text{Inter}} = \sum_{\mathcal{C}_j\in\mathcal{N}_c\setminus\mathcal{C}_i} \sum_{b'\in\mathcal{C}_j} \sum_{v'\in\mathcal{U}_j} |\mathbf{h}_{jb',iu}^H \mathbf{w}_{jb',jv'}|^2 \tag{5}$$

III. Optimal Beamforming Design for JT

Based on the considered system model, we formulate the optimal JT beamforming problem in this section, considering perfect and imperfect CSI, respectively.

A. Problem Formulation

For UE_{iu}, the DU collects the CSI from all the BSs in $\mathcal{C}_i$ and designs the beamforming vectors jointly to minimize the total transmit power consumption for serving all the UEs while satisfying the SINR requirement of individual UE. Denote γ_{iu} the SINR requirement of UE_{iu}, the JT beamforming design at DL can be formulated as

$$\text{(JT-DL)} \quad \max_{\{\mathbf{w}_{ib,iu}\}} \sum_{\mathcal{C}_i\in\mathcal{N}_c} \sum_{b\in\mathcal{C}_i} \sum_{u\in\mathcal{U}_i} \|\mathbf{w}_{ib,iu}\|^2$$
$$\text{s.t. } \text{SINR}_{iu}(\mathbf{h}) \geq \gamma_{iu}, \ \forall\, \mathcal{C}_i \in \mathcal{N}_c, u \in \mathcal{U}_i. \tag{6}$$

Due to the quadratic form of the beamforming vector $\mathbf{w}_{ib,iu}$ in $\text{SINR}_{iu}(\mathbf{h})$, (JT-DL) is a non-convex optimization problem. Besides, the beamforming vectors of different UEs are coupled, making it challenging to solve (JT-DL) directly. In

TABLE I
DUAL RELATIONSHIP

Variable	Downlink		Uplink
Channel vector	$\mathbf{h}_{ib,iu}^H$	$\Leftrightarrow$	$\mathbf{h}_{ib,iu}$
Beamforming vector	$\mathbf{w}_{ib,iu}$	$\Leftrightarrow$	$\hat{\mathbf{w}}_{ib,iu}$
Transmit Power	$\|\mathbf{w}_{ib,iu}\|^2$	$\Leftrightarrow$	$\lambda_{iu}\sigma^2$

this work, we employ the notion of *uplink-downlink duality* to solve (JT-DL) efficiently.

B. JT Beamforming with Perfect CSI

The uplink-downlink duality refers to the equivalence of the uplink beamforming and the downlink beamforming. It implies the minimum transmit power at the BS required to achieve the DL SINR requirement is identical to that for the UL. Based on this principle, one can transform the downlink beamforming design problem to the uplink, which is computationally easier to solve. This idea has been adopted in [4] for the non-JT case. This work extends the UL-DL duality to design the downlink beamforming for JT. Table I summarizes the UL-DL duality relation in our work.

The following theorem transforms (JT-DL) into the uplink counterpart.

Theorem 1. *The Lagrangian dual of (JT-DL) is the following uplink problem.*

$$(\textit{JT-UL}) \quad \min_{\{\lambda_{iu}\}} \sum_{i=1}^{N_c} \sum_{u\in\mathcal{U}_i} \lambda_{iu}\sigma^2 \quad \textit{s.t.} \Lambda_{iu} \geq \gamma_{iu} \tag{7}$$

where λ_{iu} is the dual variable of the u-th UE in the i-th cell and Λ_{iu} is the UL SINR given by

$$\Lambda_{iu} = \frac{\lambda_{iu}\sum_{b\in\mathcal{C}_i}|\hat{\mathbf{w}}_{ib,iu}^H\mathbf{h}_{ib,iu}|^2}{I_{\text{Intra}}^{\text{U}} + I_{\text{Inter}}^{\text{U}} + \sum_{b\in\mathcal{C}_i}\|\hat{\mathbf{w}}_{ib,iu}^H\|^2} \tag{8}$$

where $\hat{\mathbf{w}}_{ib,iu}$ is the UL receive beamforming vector given by

$$\hat{\mathbf{w}}_{ib,iu} = \left(\sum_{\mathcal{C}_j\in\mathcal{N}_c}\sum_{v\in\mathcal{U}_j}\lambda_{jv}\sigma^2\mathbf{h}_{ib,jv}\mathbf{h}_{ib,jv}^H + \sigma^2\mathbf{I}_{N_t}\right)^{-1}\mathbf{h}_{ib,iu}. \tag{9}$$

In addition, $I_{\text{Intra}}^{\text{U}}$ and $I_{\text{Inter}}^{\text{U}}$ are given by

$$I_{\text{Intra}}^{\text{U}} = \sum_{b\in\mathcal{C}_i}\sum_{v\in\mathcal{U}_i\setminus u}\lambda_{iv}|\hat{\mathbf{w}}_{ib,iu}^H\mathbf{h}_{ib,iv}|^2, \tag{10a}$$

$$I_{\text{Inter}}^{\text{U}} = \sum_{\mathcal{C}_j\in\mathcal{N}_c\setminus\mathcal{C}_i}\sum_{b'\in\mathcal{C}_j}\sum_{v'\in\mathcal{U}_j}\lambda_{jv'}\sigma^2|\hat{\mathbf{w}}_{ib,iu}^H\mathbf{h}_{ib,jv'}|^2. \tag{10b}$$

Proof. The proof is based on the fact that the non-convex SINR constraints in (JT-DL) can be transformed into the second-order cone constraints following [12]. Accordingly, the duality gap is zero, and strong duality holds for (JT-DL). This suggests that (JT-DL) can be solved by its Lagrangian dual problem. To this end, we first define the Lagrangian of (JT-DL) as given by

$$\begin{aligned} L(\mathbf{w}_{ib,iu}\lambda_{iu}) = &\sum_{\mathcal{C}_i\in\mathcal{N}_c}\sum_{b\in\mathcal{C}_i}\sum_{u\in\mathcal{U}_i}\mathbf{w}_{ib,iu}^H\mathbf{w}_{ib,iu} - \sum_{\mathcal{C}_i\in\mathcal{N}_c}\sum_{u\in\mathcal{U}_i}\lambda_{iu} \\ &\Big[\gamma_{iu}^{-1}\sum_{b\in\mathcal{C}_i}|\mathbf{h}_{ib,iu}^H\mathbf{w}_{ib,iu}|^2 - \sum_{b\in\mathcal{C}_i}\sum_{v\in\mathcal{U}_i\setminus u}|\mathbf{h}_{ib,iu}^H\mathbf{w}_{ib,iv}|^2 \\ &- \sum_{\mathcal{C}_j\in\mathcal{N}_c\setminus\mathcal{C}_i}\sum_{b'\in\mathcal{C}_j}\sum_{v'\in\mathcal{U}_j}|\mathbf{h}_{jb',iu}^H\mathbf{w}_{jb',jv'}|^2 - \sigma^2\Big] \end{aligned} \tag{11}$$

where $\lambda_{iu} > 0$ is the Lagrange multiplier associated with the SINR constraint of UE_{iu}. The dual function is

$$g(\lambda_{iu}) = \min_{\mathbf{w}_{ib,iu}} L(\mathbf{w}_{ib,iu}), \forall\ i, b, u. \tag{12}$$

Then the Lagrangian dual of (JT-DL), namely, the maximum of $g(\lambda_{iu})$ is

$$\begin{aligned} (\text{JT-DL Dual}) \quad &\max_{\lambda_{iu}} \sum_{\mathcal{C}_i\in\mathcal{N}_c}\sum_{u\in\mathcal{U}_i}\lambda_{iu}\sigma^2 \\ &\text{s.t}\sum_{b\in\mathcal{C}_i}\mathbf{\Theta}_{ib} \succeq (1+\gamma_{iu}^{-1})\lambda_{iu}\mathbf{h}_{ib,iu}\mathbf{h}_{ib,iu}^H, \end{aligned} \tag{13}$$

where

$$\mathbf{\Theta}_{ib} = \sum_{\mathcal{C}_i\in\mathcal{N}_c}\sum_{u\in\mathcal{U}_i}\lambda_{iu}\mathbf{h}_{ib,iu} + \mathbf{I}_{N_t} \tag{14}$$

To show (JT-DL Dual) is equivalent to (JT-DL), we first find the optimal receive beamforming vector $\mathbf{w}_{ib,iu}$ that maximizes Λ_{iu}, which is the minimum-mean-square-error (MMSE) receive beamforming as given by (9). By substituting (9) into (7), the uplink SINR constraint (7) is identical to (13). Hence, (Dual-JT-DL) is the same as (JT-UL) except that the minimization is replaced by maximization, and the inequality constraints are reversed. In addition, both problems have the optimal solution when the SINR constraints are satisfied with equality. Therefore, (JT-DL Dual) and (JT-UL) have the same solution. □

The optimal receive beamforming in (9) depends on the dual variable λ_{iu}, which must satisfy the first-order necessary condition of the optimality. To find λ_{iu}, we first combine all the terms related to $\mathbf{w}_{ib,iu}$ in (11), which yields

$$\begin{aligned} L(\mathbf{w}_{ib,iu},\lambda_{iu}) = &\sum_{\mathcal{C}_i\in\mathcal{N}_c}\sum_{u\in\mathcal{U}_i}\lambda_{iu}\sigma^2 + \sum_{\mathcal{C}_i\in\mathcal{N}_c}\sum_{b\in\mathcal{C}_i}\sum_{u\in\mathcal{U}_i}\mathbf{w}_{ib,iu}^H \\ &\left[\mathbf{I}_{N_t} - (1+\gamma_{iu}^{-1})\lambda_{iu}\mathbf{h}_{ib,iu}\mathbf{h}_{ib,iu}^H + \sum_{\mathcal{C}_j\in\mathcal{N}_c}\sum_{v\in\mathcal{U}_j}\lambda_{jv}\mathbf{h}_{ib,jv}\mathbf{h}_{ib,jv}^H\right] \\ &\times \mathbf{w}_{ib,iu}. \end{aligned} \tag{15}$$

Taking the gradient of $L(\mathbf{w}_{ib,iu},\lambda_{iu})$ with respective to $\mathbf{w}_{ib,iu}^H$ and setting the result to zero, we obtain the necessary condition for optimal λ_{iu} as

$$\lambda_{iu} = \frac{1}{\left(1+\gamma_{iu}^{-1}\right)\sum_{b\in\mathcal{C}_i}\mathbf{h}_{ib,iu}^H\mathbf{\Theta}_{ib}^{-1}\mathbf{h}_{ib,iu}}, \tag{16}$$

which is a function of $\mathbf{\Theta}_{ib}$ given in (14) that depends on λ_{iu}.

This suggests that one can iteratively optimize λ_{iu} and $\hat{\mathbf{w}}_{ib,iu}$ until convergence.

Based on the obtained receive beamformer $\hat{\mathbf{w}}_{ib,iu}$ and the UL-DL duality, the optimal DL JT beamforming can be derived from the following theorem.

Theorem 2. *The optimal DL JT beamforming $\mathbf{w}_{ib,iu}$ is a scaled version of the UL JT beamforming $\hat{\mathbf{w}}_{ib,iu}$ as given by*

$$\mathbf{w}_{ib,ij} = \sqrt{\delta_{ib,u}}\hat{\mathbf{w}}_{ib,iu}, \tag{17}$$

where $\delta_{ib,u}$ is an entry of the $N_b|\mathcal{U}_i| \times 1$ vector $\boldsymbol{\delta}_i = [\delta_{ib,u}]^T_{b\in\mathcal{C}_i,u\in\mathcal{U}_i}$ for $i = 1,\ldots,N_c$. Define the collection of $\boldsymbol{\delta}_i$ as a vector $\boldsymbol{\Delta}$ of dimension $N_cN_b|\mathcal{U}_i| \times 1$, i.e., $\boldsymbol{\Delta} = [\boldsymbol{\delta}_1, \boldsymbol{\delta}_2, \ldots, \boldsymbol{\delta}_{N_c}]^T$, which can be obtained as

$$\boldsymbol{\Delta} = \mathbf{F}^{-1}\mathbf{1}\sigma^2, \tag{18}$$

where $\mathbf{1}$ is an all-one vector of dimension $N_c|\mathcal{U}_i| \times 1$ and $\mathbf{F}$ is an $N_c|\mathcal{U}_i| \times N_cN_b|\mathcal{U}_j|$ matrix as given by

$$\mathbf{F} = \begin{bmatrix} \mathbf{F}_{1,11} & \ldots & \mathbf{F}_{1,1|\mathcal{C}_1|} & \mathbf{F}_{1,21} & \ldots & \mathbf{F}_{1,N_c|\mathcal{C}_1|} \\ \mathbf{F}_{2,11} & \ldots & \mathbf{F}_{2,1|\mathcal{C}_2|} & \mathbf{F}_{2,21} & \ldots & \mathbf{F}_{2,N_c|\mathcal{C}_2|} \\ \vdots & \ddots & \vdots & \vdots & \ddots & \vdots \\ \mathbf{F}_{N_c,11} & \ldots & \mathbf{F}_{N_c,1|\mathcal{C}_{N_c}|} & \mathbf{F}_{N_c,21} & \ldots & \mathbf{F}_{N_c,N_c|\mathcal{C}_{N_c}|} \end{bmatrix} \tag{19}$$

where the (u,v)-th entry of each $|\mathcal{U}_i| \times |\mathcal{U}_j|$ sub-matrix $\mathbf{F}_{i,jb}$ is defined as

$$\mathbf{F}_{i,jb}(u,v) = \begin{cases} \gamma_{iu}^{-1}|\hat{\mathbf{h}}_{ib,iu}^H\hat{\mathbf{w}}_{ib,iu}|^2, & \text{if } j = i \text{ and } v = u, \\ -|\tilde{\mathbf{h}}_{ib,iu}^H\hat{\mathbf{w}}_{ib,iv}|^2, & \text{if } j = i \text{ and } v \neq u, \\ -|\tilde{\mathbf{h}}_{mb,iu}^H\hat{\mathbf{w}}_{jb,jv}|^2, & \text{if } j \neq i. \end{cases} \tag{20}$$

Proof. The proof can be found in [13]. □

A complete algorithm for iteratively obtaining the optimal DL JT beamforming vectors $\mathbf{w}_{ib,iu}$ is summarized in Algorithm 1, which is referred to as non-robust JT beamforming (NR-JTBF) in this work. The convergence of Algorithm 1 to the global optimal solution is guaranteed following the similar arguments in [4], which is omitted here due to space limit.

Algorithm 1 Non-Robust JT Beamforming (NR-JTBF)

Input: CSI $\mathbf{h}_{ib,iu}$, $\forall\ \mathcal{C}_i \in \mathcal{N}_c$, $b \in \mathcal{C}_i$, $u \in \mathcal{U}_i$.

1: Initialize $\lambda_{iu} = 1$, $\forall\ i, u$.
2: **repeat**
3: Compute $\boldsymbol{\Theta}_{ib}$ using (14).
4: Compute λ_{iu} using (16).
5: Compute $\hat{\mathbf{w}}_{ib,iu}$ using (9).
6: Compute the scaling factor $\delta_{i,bu}$ from (18).
7: Update $\mathbf{w}_{ib,iu}$ using (17).
8: **until** the predefined stopping criterion is met.

Output:

9: Optimal downlink JT beamformers $\mathbf{w}_{ib,iu}, \forall\ i, b, u$.

C. JT Beamforming with Imperfect CSI

Algorithm 1 uses the accurate CSI as the input. In practice, CSI acquired by each BS contains unknown estimation errors and thus is imperfect. Consequently, the beamforming vectors derived from imperfect CSI may not achieve the required SINR. This motivates us to revisit (JT-DL) and design robust beamforming for JT that minimizes the total transmit power while ensuring the target SINR with a certain probability. The resultant problem formulation based on estimated CSI is given below.

$$\begin{aligned} \text{(Robust JT-DL)} \quad & \min_{\mathbf{w}_{ib,iu}} \sum_{\mathcal{C}_i\in\mathcal{N}_c}\sum_{b\in\mathcal{C}_i}\sum_{u\in\mathcal{U}_i} \|\mathbf{w}_{ib,iu}\|^2 \\ & \text{s.t } \Pr[\text{SINR}_{iu}(\tilde{\mathbf{h}}) \geq \gamma_{iu}] \geq 1 - \rho_{iu} \end{aligned} \tag{21}$$

where $\rho_{iu} \in (0,1)$. By imposing constraint (21), UE_{iu} is guaranteed to satisfy the target SINR with the probability no less than $1 - \rho_{iu}$. (Robust JT-DL) is non-convex since the beamforming vectors $\mathbf{w}_{ib,iu}$ are of quadratic forms and constraint (21) is a probability function without closed-form. Unfortunately, UL-DL duality can only handle deterministic constraints. To remedy this, we use the SDR technique to convert (Robust JT-DL) into a convex problem.

Firstly, we linearize the objective function of (Robust JT-DL) by introducing the rank-one positive semidefinite (PSD) matrix $\mathbf{W}_{ib,iu} = \mathbf{w}_{ib,iu}\mathbf{w}_{ib,iu}^H$. As a result, the quadratic term $\|\mathbf{w}_{ib,iu}\|^2$ is replaced by $\text{Tr}(\mathbf{W}_{ib,iu})$, which is a linear operation. Meanwhile, constraint (21) can be rewritten as

$$\begin{aligned} &\Pr\Bigg[\gamma_{iu}^{-1}\sum_{b\in\mathcal{C}_i}(\tilde{\mathbf{h}}_{ib,iu}+\mathbf{e}_{ib,iu})^H\mathbf{W}_{ib,iu}(\tilde{\mathbf{h}}_{ib,iu}+\mathbf{e}_{ib,iu}) \\ &-\sum_{b\in\mathcal{C}_i}\sum_{v\in\mathcal{U}_i\setminus u}(\tilde{\mathbf{h}}_{ib,iu}+\mathbf{e}_{ib,iu})^H\mathbf{W}_{ib,iv}(\tilde{\mathbf{h}}_{ib,iu}+\mathbf{e}_{ib,iu}) \\ &-\sum_{\mathcal{C}_j\in\mathcal{N}_c\setminus\mathcal{C}_i}\sum_{b'\in\mathcal{C}_j}\sum_{u'\in\mathcal{U}_j}(\tilde{\mathbf{h}}_{jb',iu}+\mathbf{e}_{jb',iu})^H\mathbf{W}_{jb',just} \\ &(\tilde{\mathbf{h}}_{jb',iu}+\mathbf{e}_{jb',iu}) \geq \sigma^2\Bigg] \geq 1-\rho_{iu}, \end{aligned} \tag{22}$$

which does not have a closed form and thus is difficult to handle. To simplify (22) into a more tractable form, we substitute (2) into (22) and define the following notations.

$$\begin{aligned} \boldsymbol{\Omega}_{ib,iu} &\triangleq \mathbf{Q}_{ib,iu}^{1/2}(\gamma_{iu}^{-1}\mathbf{W}_{ib,iu} - \sum_{v\in\mathcal{U}_i\setminus u}\mathbf{W}_{ib,iv})\mathbf{Q}_{ib,iu}^{1/2}, \\ \boldsymbol{\Omega}_{jb',iu} &\triangleq -\mathbf{Q}_{jb',iu}^{1/2}\sum_{u'\in\mathcal{U}_j}\mathbf{W}_{jb',ju'}\mathbf{Q}_{jb',iu}^{1/2}, \\ \boldsymbol{\omega}_{ib,iu} &\triangleq \mathbf{Q}_{ib,iu}^{1/2}(\gamma_{iu}^{-1}\mathbf{W}_{ib,iu} - \sum_{v\in\mathcal{U}_i\setminus u}\mathbf{W}_{ib,iv})\tilde{\mathbf{h}}_{ib,iu}, \\ \boldsymbol{\omega}_{jb',iu} &\triangleq -\mathbf{W}_{jb',iu}^{1/2}\sum_{u'\in\mathcal{U}_j}\mathbf{W}_{jb',ju'}\tilde{\mathbf{h}}_{jb',iu}, \\ d_{ib,iu} &\triangleq \tilde{\mathbf{h}}_{ib,iu}^H(\gamma_{iu}^{-1}\mathbf{W}_{ib,iu} - \sum_{v\in\mathcal{U}_i}\mathbf{W}_{ib,iv})\tilde{\mathbf{h}}_{ib,iv}, \\ d_{jb',iu} &\triangleq -\tilde{\mathbf{h}}_{jb',iu}^H\sum_{u'\in\mathcal{U}_j}\mathbf{W}_{jb',ju'})\tilde{\mathbf{h}}_{jb',iu}. \end{aligned} \tag{23}$$

Then (22) can be expressed as

$$\Pr\Bigg[\sum_{\mathcal{C}_l\in\mathcal{N}_c}\sum_{b\in\mathcal{C}_l}\Big(\mathbf{v}_{lb,iu}^H\boldsymbol{\Omega}_{lb,iu}\mathbf{v}_{lb,iu}+\boldsymbol{\omega}_{lb,iu}^H\mathbf{v}_{lb,iu} + \mathbf{v}_{lb,iu}^H\boldsymbol{\omega}_{lb,iu}+d_{lb,iu}\Big)\geq\sigma^2\Bigg]\geq 1-\rho_{iu},\ \forall\,\mathcal{C}_i\in\mathcal{N}_c, u\in\mathcal{C}_i. \tag{24}$$

Note that $\boldsymbol{\omega}_{lb,iu}^H\mathbf{v}_{lb,iu}+\mathbf{v}_{l\beta,iu}^H\boldsymbol{\omega}_{lb,iu}=2\mathrm{Re}(\mathbf{v}_{lb,iu}^H\boldsymbol{\omega}_{lb,iu})$. Hence, (24) can be represented as

$$\Pr\Bigg[\sum_{\mathcal{C}_l\in\mathcal{N}_c}\sum_{b\in\mathcal{C}_l}\Big(\mathbf{v}_{lb,iu}^H\boldsymbol{\Omega}_{lb,iu}\mathbf{v}_{lb,iu}+2\mathrm{Re}(\mathbf{v}_{lb,iu}^H\boldsymbol{\omega}_{lb,iu}\Big) \geq\sigma^2-\sum_{\mathcal{C}_l\in\mathcal{N}_c}\sum_{\beta\in\mathcal{C}_l}d_{lb,iu}\Bigg]\geq 1-\rho_{iu},\ \forall\,\mathcal{C}_i\in\mathcal{N}_c, u\in\mathcal{C}_i. \tag{25}$$

Let $K=N_cN_b$. Then we can rewrite (25) as

$$\Pr\Bigg[\sum_{k=1}^{K}\Big(\hat{\mathbf{v}}_{k,iu}^H\hat{\boldsymbol{\Omega}}_{k,iu}\hat{\mathbf{v}}_{k,iu}+2\mathrm{Re}(\hat{\mathbf{v}}_{k,iu}^H\hat{\boldsymbol{\omega}}_{k,iu}\Big) \geq\sigma^2-\sum_{k=1}^{K}\hat{d}_{k,iu}\Bigg]\geq 1-\rho_{iu}. \tag{26}$$

where $\hat{\mathbf{v}}_{k,iu}=\mathbf{v}_{lb,iu}$ for $k=(l-1)N_b+b$. Likewise, $\hat{\boldsymbol{\Omega}}_{k,iu}=\boldsymbol{\Omega}_{lb,iu}\in\mathbb{H}^{N_t}$, $\hat{\boldsymbol{\omega}}_{k,iu}=\boldsymbol{\omega}_{lb,iu}\in\mathbb{C}^{N_t}$ and $\hat{d}_{k,iu}=d_{lb,iu}$. Here $\mathbb{H}^{N_t}$ represents the N_t-dimensional Hermitian matrix. Although (26) is much simpler than (22), it remains a probabilistic inequality without a closed form, and thus a certain approximation is necessary. Since (26) contains the quadratic form of $\hat{\mathbf{v}}_{k,iu}^H$, we are motivated to apply the Bernstein-type inequality, which bounds the probability of the quadratic form of complex random variables deviating from its mean. To this end, define

$$g_{k,iu}=\hat{\mathbf{v}}_{k,iu}^H\hat{\boldsymbol{\Omega}}_{k,iu}\hat{\mathbf{v}}_{k,iu}+2\mathrm{Re}\left(\hat{\boldsymbol{\omega}}_{k,iu}^H\hat{\mathbf{v}}_{k,iu}\right), \tag{27}$$

$\forall\ k=1,\ldots,K$, $\mathcal{C}_i\in\mathcal{N}_c$, and $u\in\mathcal{U}_i$. Then the following Lemma is introduced.

Lemma 1. *For any $\tau_{iu}>0$,*

$$\Pr\Bigg[\sum_{k=1}^{K}g_{k,iu}\geq\sum_{k=1}^{K}\mathrm{Tr}(\hat{\boldsymbol{\Omega}}_{k,iu})-\sqrt{2\tau_{iu}}\Big(\sum_{k=1}^{K}\big(\|\hat{\boldsymbol{\Omega}}_{k,iu}\|^2 +2\|\hat{\boldsymbol{\omega}}_{k,iu}\|^2\big)\Big)^{1/2}-\tau_{iu}\lambda^-(\hat{\boldsymbol{\Omega}})\Bigg]\geq 1-e^{-\tau_{iu}}. \tag{28}$$

where $\lambda^-(\hat{\boldsymbol{\Omega}})=\max\{\lambda_{\max}(-\hat{\boldsymbol{\Omega}}_{1,iu}),\ldots,\lambda_{\max}(-\hat{\boldsymbol{\Omega}}_{K,iu}),0\}$ with $\lambda_{\max}(-\hat{\boldsymbol{\Omega}}_{k,iu})$ denoting the maximum eigenvalue of the matrix $(-\hat{\boldsymbol{\Omega}}_{k,iu})$.

Proof. The proof is motivated from [14], which considers robust hybrid beamforming without multi-cell cooperation. The idea is to find a conservative convex approximation to the probabilistic constraint (26) with the aid of the Bernstein-type inequality [15]. For our problem, a Bernstein-type inequality can be established as follows.

Let $S=K\cdot 2N_t$ for $K=N_cN_b$, $\boldsymbol{\alpha}=[\alpha_1,\ldots,\alpha_S]^T\in\mathbb{R}^S$ and $\boldsymbol{\beta}=[\beta_1,\ldots,\beta_S]^T\in\mathbb{R}^S$, where $\mathbb{R}^S$ denotes the S-dimensional real vector. Besides, $\boldsymbol{\nu}=[\nu_1,\ldots,\nu_S]^T\in\mathbb{R}^S$ be a random vector where $\nu_1,\ldots,\nu_S$ are i.i.d. real random variables following the standard normal distribution $\mathcal{N}(0,1)$. Define

$$G=\sum_{s=1}^{S}\Big(\alpha_s\nu_s^2+2\beta_s\nu_s\Big). \tag{29}$$

Then, given $\tau>0$, the following result holds.

$$\Pr\left[G\geq\sum_{s=1}^{S}\alpha_s-2\sqrt{\tau}\sqrt{\sum_{s=1}^{S}\left(\alpha_s{}^2+2\beta_s{}^2\right)}-2\tau\alpha^-\right] \geq 1-e^{-\tau}, \tag{30}$$

where $\alpha^-\triangleq\max\{\max\{-\alpha_s\mid 1\leq s\leq S\},0\}$. (30) is a real-valued constraint but can be applied to handle complex-valued variables. This is achieved with the aid of the following variables.

$$\bar{\boldsymbol{\Omega}}_{k,iu}=\frac{1}{2}\begin{bmatrix}\mathrm{Re}(\hat{\boldsymbol{\Omega}}_{k,iu}) & -\mathrm{Im}(\hat{\boldsymbol{\Omega}}_{k,iu})\\ \mathrm{Im}(\hat{\boldsymbol{\Omega}}_{k,iu}) & \mathrm{Re}(\hat{\boldsymbol{\Omega}}_{k,iu})\end{bmatrix}\in\mathbb{S}^{2N_t}, \tag{31a}$$

$$\bar{\boldsymbol{\omega}}_{k,iu}=\frac{1}{\sqrt{2}}\begin{bmatrix}\mathrm{Re}(\hat{\boldsymbol{\omega}}_{k,iu})\\ \mathrm{Im}(\hat{\boldsymbol{\omega}}_{k,iu})\end{bmatrix}\in\mathbb{R}^{2N_t}, \tag{31b}$$

$$\bar{\mathbf{v}}_{k,iu}=\sqrt{2}\begin{bmatrix}\mathrm{Re}(\mathbf{v}_{k,iu})\\ \mathrm{Im}(\mathbf{v}_{k,iu})\end{bmatrix}\sim\mathcal{CN}\left(\mathbf{0},\mathbf{I}_{2N_t}\right), \tag{31c}$$

for all $k\in\{1,\ldots,K\},\mathcal{C}_i\in\mathcal{N}_c$, and $u\in\mathcal{U}_i$. Denote $\bar{v}_{k,iu}[l]$ and $\bar{\omega}_{k,iu}[l]$ the lth element of $\bar{\mathbf{v}}_{k,iu}$ and $\bar{\boldsymbol{\omega}}_{k,iu}$, respectively. Here, $\mathbb{S}$ denotes the real symmetric matrix. Using (31a)-(31c), and decomposing $\bar{\boldsymbol{\Omega}}_{k,iu}$ as $\bar{\boldsymbol{\Omega}}_{k,iu}=\mathbf{U}_{k,iu}\boldsymbol{\Lambda}_{k,iu}\mathbf{U}_{k,iu}^T$ through eigenvalue decomposition, where $\mathbf{U}_{k,iu}$ is an orthogonal matrix and $\boldsymbol{\Lambda}_{k,iu}=\mathrm{diag}(\lambda_{k,iu}[l])$ is a diagonal matrix with $\lambda_{k,iu}[l]$ denoting the l-th eigenvalue of $\bar{\boldsymbol{\Omega}}_{k,iu}$, (27) can be rewritten as

$$\begin{aligned}g_{k,iu}&=\bar{\mathbf{v}}_{k,iu}^T\bar{\boldsymbol{\Omega}}_{k,iu}\bar{\mathbf{v}}_{k,iu}+2\bar{\boldsymbol{\omega}}_{k,iu}^T\bar{\mathbf{v}}_{k,iu}\\ &\overset{\text{(i)}}{=}\tilde{\mathbf{v}}_{k,iu}^T\boldsymbol{\Lambda}_{l,iu}\tilde{\mathbf{v}}_{k,iu}^T+2\tilde{\boldsymbol{\omega}}_{k,iu}^T\tilde{\mathbf{v}}_{k,iu}\\ &\overset{\text{(ii)}}{=}\sum_{l=1}^{2N_t}\Big(\lambda_{k,iu}[l]\tilde{v}_{k,iu}^2[l]+2\tilde{\omega}_{k,iu}[l]\tilde{v}_{k,iu}[l]\Big),\end{aligned} \tag{32}$$

where (i) is obtained by defining $\tilde{\mathbf{v}}_{k,iu}=\mathbf{U}_{k,iu}^T\bar{\mathbf{v}}_{k,iu}$ and $\tilde{\boldsymbol{\omega}}_{k,iu}=\mathbf{U}_{k,iu}^T\bar{\boldsymbol{\omega}}_{k,iu}$, and in (ii), $\tilde{v}_{k,iu}[l]$ and $\tilde{\omega}_{k,iu}[l]$ is the l-th element of $\tilde{\mathbf{v}}_{k,iu}$ and $\tilde{\boldsymbol{\omega}}_{k,iu}$, respectively. One can see that (32) follows the same form as (29). Similar to (29), denote G' the sum of $g_{k,iu},\ \forall\ k=1,\ldots,K$, i.e.,

$$\begin{aligned}G'&=\sum_{k=1}^{K}g_{k,iu}\\ &=\sum_{k=1}^{K}\sum_{l=1}^{2N_t}\Big(\lambda_{k,iu}[l]\tilde{v}_{k,iu}^2[l]+2\tilde{\omega}_{k,iu}[l]\tilde{v}_{k,iu}[l]\Big).\end{aligned} \tag{33}$$

According to (30), we obtain the following inequality.

$$\Pr\Big[G' \geq \sum_{k=1}^{K}\sum_{l=1}^{2N_t}\lambda_{k,iu}[l] - 2\sqrt{\tau_{iu}} \sqrt{\sum_{k=1}^{K}\sum_{l=1}^{2N_t}\lambda_{k,iu}^2[l] + 2\tilde{\omega}_{k,iu}^2[l]} - 2\tau_{iu}\tilde{\alpha}^-\Big] \geq 1 - e^{-\tau_{iu}}, \quad (34)$$

where

$$\tilde{\alpha}^- \triangleq \max\{\max_l\{-\lambda_{1,iu}[l]\},\ldots,\max\{\max_l\{-\lambda_{K,iu}[l],0\},$$

for all $\mathcal{C}_i \in \mathcal{N}_c$, $u \in \mathcal{U}_i$. (34) can be written more compactly by using the property of matrix trace, e.g., $\sum_{l=1}^{2N_t}\lambda_{k,iu}[l] = \mathrm{Tr}(\bar{\mathbf{\Omega}}_{k,iu})$ and also, $\bar{\mathbf{\Omega}}_{k,iu}$ has the same eigenvalues as $\hat{\mathbf{\Omega}}_{k,iu}$. Hence, (34) can be rewritten as

$$\Pr\Big[G' \geq \sum_{k=1}^{K}\mathrm{Tr}(\hat{\mathbf{\Omega}}_{k,iu}) - 2\sqrt{\tau_{iu}} \sqrt{\sum_{k=1}^{K}\frac{1}{2}\|\hat{\mathbf{\Omega}}_{k,iu}\|^2 + \|\hat{\boldsymbol{\omega}}_{k,iu}\|^2} - \tau_{iu}\lambda^-(\hat{\mathbf{\Omega}})\Big] \geq 1 - e^{-\tau_{iu}}, \quad (35)$$

which is obtained by noting that

$$\sum_{l=1}^{2N_t}\lambda_{k,iu}^2[l] = \|\bar{\mathbf{\Omega}}_{k,iu}\|^2 = \frac{1}{2}\|\hat{\mathbf{\Omega}}_{k,iu}\|^2, \quad (36a)$$

$$2\sum_{l=1}^{2N_t}\tilde{\omega}_{k,iu}^2[l] = 2\|\tilde{\boldsymbol{\omega}}_{k,iu}\|^2 = 2\|\bar{\boldsymbol{\omega}}_{k,iu}\|^2 = \|\hat{\boldsymbol{\omega}}_{k,iu}\|^2 \quad (36b)$$

$$\begin{aligned}\tilde{\alpha}^- &= \max\{\lambda_{\max}(-\bar{\mathbf{\Omega}}_{1,iu}),\cdots,\lambda_{\max}(-\bar{\mathbf{\Omega}}_{K,iu}),0\}\\ &= \frac{1}{2}\max\{\lambda_{\max}(-\hat{\mathbf{\Omega}}_{1,iu}),\cdots,\lambda_{\max}(-\hat{\mathbf{\Omega}}_{K,iu}),0\}\\ &\triangleq \frac{1}{2}\lambda^-(\hat{\mathbf{\Omega}}).\end{aligned} \quad (36c)$$

It is easy to check that (35) is identical to (28) that completes the proof. □

By letting $\rho_{iu} = e^{-\tau_{iu}}$ and comparing (28) with (26), we can see that the following inequality serves as a sufficient condition to satisfy (26).

$$\sum_{k=1}^{K}\mathrm{Tr}(\hat{\mathbf{\Omega}}_{k,iu}) - \sqrt{2\tau_{iu}}\Big(\sum_{k=1}^{K}\big(\|\hat{\mathbf{\Omega}}_{k,iu}\|^2 + 2\|\hat{\boldsymbol{\omega}}_{k,iu}\|^2\big)\Big)^{1/2} - \tau_{iu}\lambda^-(\hat{\mathbf{\Omega}}) \geq \sigma^2 - \sum_{k=1}^{K}\hat{d}_{k,iu}, \quad \forall\, \mathcal{C}_i \in \mathcal{N}_c, u \in \mathcal{U}_i. \quad (37)$$

Recall $K = N_cN_b$ and $k = (l-1)N_b+b$, (37) can be rewritten as

$$\sum_{\mathcal{C}_l\in\mathcal{N}_c}\sum_{b\in\mathcal{C}_l}\Big(\mathrm{Tr}(\mathbf{\Omega}_{lb,iu}) + d_{lb,iu}\Big) - \tau_{iu}\lambda^-(\mathbf{\Omega}) - \sigma^2 \geq \sqrt{2\tau_{iu}}\Big(\sum_{\mathcal{C}_l\in\mathcal{N}_c}\sum_{b\in\mathcal{C}_l}\|\mathbf{C}_{lb,iu}\|^2\Big)^{1/2}. \quad (38)$$

where $\mathbf{C}_{lb,iu} = [\mathbf{\Omega}_{lb,iu}\ \sqrt{2}\boldsymbol{\omega}_{lb,iu}]$. Since $\lambda^-(\mathbf{\Omega})$ in (38) is non-convex, we introduce the slack variable $x_{iu} \geq 0$ such that (38) is equivalent to

$$\sqrt{\sum_{l\in\mathcal{N}_c}\sum_{b\in\mathcal{C}_l}\|\mathbf{C}_{lb,iu}\|^2} \leq \frac{1}{\sqrt{2\tau_{iu}}}\Big[\sum_{l\in\mathcal{N}_c}\sum_{b\in\mathcal{C}_l}\Big(\mathrm{Tr}(\mathbf{\Omega}) + d_{l\beta,iu}\Big) - \tau_{iu}x_{iu} - \sigma^2\Big],$$

along with $x_{iu}\mathbf{I}_{N_t} + \mathbf{Q}_{lb,iu} \succeq \mathbf{0}$, $\forall\ \mathcal{C}_i,\mathcal{C}_l \in \mathcal{N}_c$, $b \in \mathcal{C}_l$, and $u \in \mathcal{U}_i$. As a result, we obtain a convex formulation for (Robust JT-DL) as follows.

$$\begin{aligned}(\text{Robust JT-DL}^2)\quad &\min_{\mathbf{W}_{ib,iu},x_{iu}\geq 0}\ \sum_{\mathcal{C}_i\in\mathcal{N}_c}\sum_{b\in\mathcal{C}_i}\sum_{u\in\mathcal{U}_i}\mathrm{Tr}(\mathbf{W}_{ib,iu})\\ \text{s.t}\quad &\sqrt{\sum_{\mathcal{C}_l\in\mathcal{N}_c}\sum_{b\in\mathcal{C}_l}\|\mathbf{C}_{lb,iu}\|^2} \leq \frac{1}{\sqrt{2\tau_{iu}}}\\ &\qquad\Big[\sum_{\mathcal{C}_l\in\mathcal{N}_c}\sum_{b\in\mathcal{C}_l}\Big(\mathrm{Tr}(\mathbf{\Omega}) + d_{lb,iu}\Big) - \tau_{iu}x_{iu} - \sigma^2\Big],\\ &x_{iu}\mathbf{I}_{N_t} + \mathbf{Q}_{lb,iu} \succeq \mathbf{0},\ \forall\ i,b,u.\end{aligned} \quad (39)$$

With the aid of SDR formulation and the Bernsteirn-type inequality, (Robust JT-DL^2) is convex that can be solved numerically. The obtained solution $\mathbf{W}_{ib,iu}$, which is referred to as robust-JT beamforming (R-JTBF), is not necessarily a rank-one matrix, in which case the Gaussian randomization technique can be used to find an approximated solution [9].

IV. Simulation Results

The performance of the proposed NR-JTBF and R-JTBF are evaluated by simulating the three-cell scenario in Fig. 1. In each cell, a UE is randomly distributed and 10,000 channel realizations are generated for each UE location. The channel vector between BS_{ib} and UE_{iu} is modeled as $\mathbf{h}_{ib,iu} = \sqrt{\beta_{ib,iu}}\psi_{ib,iu}\varphi_{ib,iu}(\tilde{\mathbf{h}}_{ib,iu} + \mathbf{e}_{ib,iu})$, where $\beta_{ib,iu}$ and $\psi_{ib,iu}$ capture the distance-dependent pathloss and lognormal shadowing, respectively, and $\varphi_{ib,iu}$ reflects the transmit-receive antenna gain. Besides, $\tilde{\mathbf{h}}_{ib,iu} \sim \mathcal{CN}(\mathbf{0},\mathbf{I}_{N_t})$ is the Rayleigh fading coefficient. Table IV lists the simulation parameters.

TABLE II
Simulation Parameters

Parameter	Value
Number of cells N_c	3
Number of BSs per cell N_b	3
Number of UEs per cell	1
Number of BS antennas N_t	4
Inter-cell distance	500 m
BS maximum power	24 dBm
Antenna gain $\varphi_{ib,iu}$	5 dBi
System bandwidth	10 MHz
Noise power spectral density	-174 dBm/Hz
Pathloss over a distance of d km	$145.4 + 37.5\log_{10} d$
CSI error radius ϵ	$\sqrt{0.1}$
SINR requirement γ_{iu}	12 dB
SINR violation probability ρ_{iu}	0.1

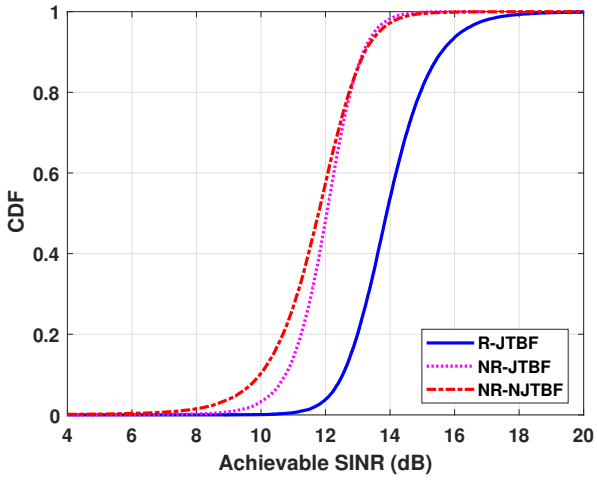

Fig. 2. The CDF of the achievable SINR.

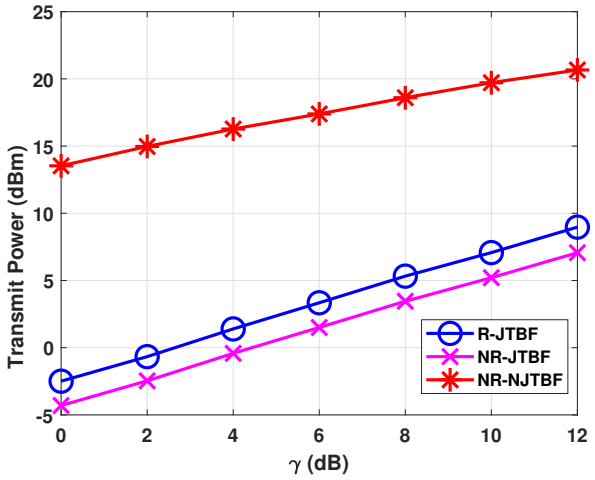

Fig. 3. Transmit power vs. SINR target γ.

We first show the distribution of the achievable SINR in terms of the cumulative distribution function (CDF) in Fig. 2. Here, the traditional multi-user MIMO beamforming based on imperfect CSI without JT referred to as non-robust non-JT beamforming (NR-NJTBF), is included for comparison. NR-NJTBF is a special case of the proposed NR-JTBF with one BS per cell, i.e., $N_b = 1$. One can see that R-JTBF significantly improves the achievable SINR over NR-JTBF and NR-NJTBF. The probability of violating the SINR target of 12 dB is only 0.04, which is much less than the prescribed probability of 0.1. As to NT-JTBF and NR-NJTBF, the likelihood of SINR target violation is 49% and 61%, respectively. The result justifies the importance of robust beamforming for practical systems with imperfect CSI.

Fig. 3 plots the transmit power used by different beamforming schemes for satisfying the SINR target γ, which is assumed to be identical for all UEs. As γ increases, a higher transmit power is required to meet the SINR target as expected. Given a specific SINR target, the proposed R-JTBF consumes extra power of 2 dBm compared with the proposed NR-JTBF. The additional power consumption of R-JTBF can be regarded as the cost for compensating the SINR loss due to imperfect CSI and the same price is maintained even for a more stringent SINR target. Comparing with NR-NJTBF, both the proposed R-JTBF and NR-JTBF dramatically reduce the required transmit power. For example, R-JTBF consumes 12 dBm less power than NR-NJTBF when $\gamma = 12$ dB. The power-saving gain attributes to JT, which uses the antennas across different BSs and, thus, it achieves a better beamforming gain than the beamforming scheme without JT.

We further examine the performance of R-JTBF under varied QoS requirements in terms of the designated SINR satisfaction probability $1 - \rho$. Here, the commonly considered multi-user beamforming, namely zero-forcing (ZF), is included in the comparison. The ZF beamforming vectors, as given by $\mathbf{w}_{ib,iu}^{\mathrm{ZF}} = \mathbf{h}_{ib,iu}(\mathbf{h}_{ib,iu}^H \mathbf{h}_{ib,iu})^{-1}$ for UE_{iu} served by BS_{ib}, aim to cancel all the interference, including intra-cell and inter-cell interference by jointly designing the beamforming using all the antennas in the network. This can be implemented at the CU, which collects global CSI. Fig. 4 shows the SINR satisfactory rate achieved by different schemes versus the designated SINR satisfactory probability. Except ZF without considering a specific QoS requirement, the same SINR target of 6 dB is applied to the rest schemes. In addition, the SINR satisfaction probability $(1-\rho)$ is varied from 0.1 to 0.9 for R-JTBF. The SINR satisfaction rate of R-JTBF consistently exceeds the designated satisfaction probability and is higher than the rest schemes. For the three non-robust beamforming schemes, the SINR satisfaction rate of ZF, NR-JTBF, and NR-NJTBF is about 63%, 51%, and 42%, respectively. It is worth pointing out that ZF outperforms NR-JTBF and NR-NJTBF because it utilizes all the available antennas in the network to determine the beamforming vector for each user, while the rest two use the antennas within the same cell only. Thus, the gain of ZF is the direct consequence of using N_c times more antennas than that of NR-JTBF and $N_c N_b$ times more antennas than that of NR-NJTBF with a single-BS operation.

Finally, we investigate how much spectral efficiency can be improved per unit of power. To this end, we define the power efficiency as the ratio between the spectral efficiency evaluated as $\sum_{\mathcal{C}_i \in \mathcal{N}_c} \sum_{u \in \mathcal{U}_i} \log_2(1 + \mathrm{SINR}_{iu})$ and the total transmit power. Fig. 5 illustrates the power efficiency as a function of the antenna per BS N_t. Increasing N_t leads to improved SINR due to a higher spatial DoF. Also, the required power to meet the SINR target is reduced by using a larger antenna array at the BS. As a result, each unit of energy can be used more efficiently, as seen from the increasing trend in Fig. 5. Both JT beamforming schemes, namely R-JTBF and NR-JTBF, have a much higher power efficiency than NR-NJTBF and ZF. The energy efficiency of R-JTBF is slightly worst than that of

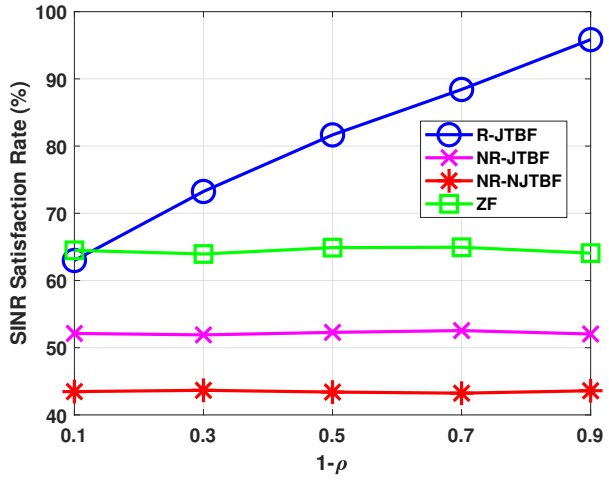

Fig. 4. SINR satisfaction rate vs. predefined SINR satisfaction probability.

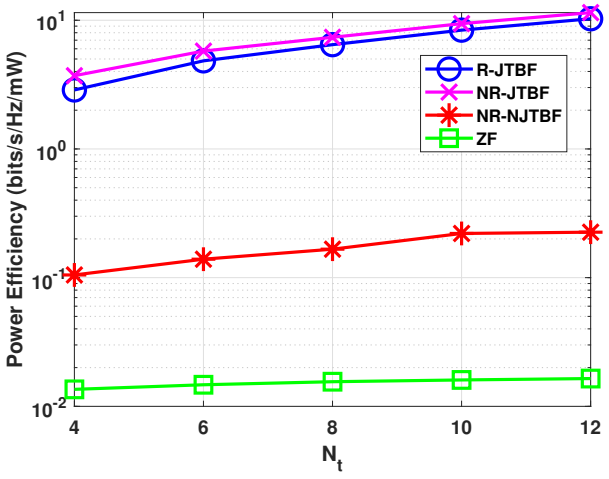

Fig. 5. Power efficiency vs. number of antennas per BS.

NR-JTBF because of a higher transmit power paid to achieve the desired SINR subject to CSI error as seen in Fig. 3. On the other hand, ZF has the worst energy efficiency because it uses all the available power at the BS. As a result, ZF is not energy efficient despite a certain spectral efficiency increase as N_t increases.

V. Conclusion

This work extends the previous work on the multi-cell coordinated beamforming design to the JT mode. It is shown that when perfect CSI is not available, the robust JT beamforming scheme significantly improves the achievable SINR, thereby increasing the SINR satisfaction rate over the non-robust JT beamforming scheme and ZF-based beamforming scheme. The improvement of the robust JT beamforming scheme comes at the cost of slightly increased transmit power compared to the non-robust JT beamforming scheme. Still, the cost is nearly negligible as the number of antennas per BS increases. On the other hand, the non-robust non-JT beamforming scheme incurs a dramatic increase in the total transmit power as the target SINR increases. Hence, its power efficiency is much lower than the two JT beamforming schemes. The results of this work demonstrate that signal enhancement and interference cancellation can be achieved simultaneously through multi-cell cooperation that yields promising gains even without perfect CSI.

***Abstract*—The lattice-reduction (LR) preprocessing can effectively improve the performance of multiple-input multiple-output (MIMO) systems especially in the highly correlated channel. This study designed a deep-learning model for the LR preprocessing in the MIMO system. Based on the AlphaGo Zero architecture, this paper proposes a deep learning-based lattice reduction (DLLR) algorithm by using reinforcement learning in the AlphaGo Zero. This work investigated the performances of the DLLR in the time-varying correlated MIMO channel environments. Compare with the traditional LR-aided MIMO algorithm, the simulation results show that the DLLR can greatly improve the orthogonality of the MIMO matrices for the detection and the DLLR-aided MIMO system has better bit-error-rate performance than the LR-aided MIMO system.**

I. Introduction

Multiple-input multiple-output (MIMO) [1] system can improve the spectral efficiency of a wireless system with limited bandwidth and the MIMO channel characteristics have strong impact on the spectral efficiency and detection performance of the MIMO system. Lattice reduction preprocessing [2] was first proposed to improve the detection performance because it can transform a correlated MIMO matrix into a more orthogonal form. An orthogonal channel matrix means that the transmission is free from the interference of other transmit antennas. Therefore, the detection performance is increased. Since the benefit of the lattice reduction, lattice reduction aided MIMO detector [3] was used to enhance the detection performance. Recently, various deep learning (DL) techniques have been adopted in communication systems to solve optimization problems because of their better performances, such as DL channel estimation [4], DL MIMO detection [5]. However, deep learning techniques have not been applied to lattice reduction preprocessing for the MIMO detection because the popular DL models are not suitable for lattice reduction. Therefore, this study proposed to use the DL architecture of AlphaGo Zero [6] to construct the discrete model of the QAM constellation. Then, we used correlated MIMO channel systems to generat the training data for training the AlphaGo Zero model. An initial neural network was used to perform the the Monte-Carlo tree search [7] for data generation. In the inference phase, we applied the reinforcement learning to the AlphaGo Zero model to implement the lattice reduction algorithm. In the experiments, the LR-aided MIMO system was simulated and the proposed LR preprocessing and MIMO detection were performed to evaluate the bit error rate performance.

The rest of this paper is organized as follows. Section II introduces the time-correlated MIMO system and the lattice reduction algorithm. Section III discusses the design issues of the lattice reduction and introduces the architecture of AlphaGo Zero. Section IV presents the proposed DLLR algorithm. Section V shows the simulation final results. Finally, Section VI concludes this paper.

II. MIMO System and Lattice Reduction

A. MIMO System

An $N_r \times N_t$ MIMO system can be expressed by

$$\mathbf{y} = \mathbf{H}\mathbf{x} + \mathbf{n}, \tag{1}$$

where $\mathbf{y}$ is an $N_r \times 1$ received signal vector, $\mathbf{x}$ is an $N_t \times 1$ transmitted signal vector, $\mathbf{H}$ is an $N_r \times N_t$ channel matrix, and $\mathbf{n}$ is an $N_r \times 1$ vector of i.i.d $\mathcal{CN}(0, \sigma_n^2)$ additive Gaussian noise. The complex channel model can be equivalent to the real channel model as follows:

$$\mathbf{y}_r = \mathbf{H}_r\mathbf{x}_r + \mathbf{n}_r = \begin{bmatrix} \Re(\mathbf{H}) & -\Im(\mathbf{H}) \\ \Im(\mathbf{H}) & \Re(\mathbf{H}) \end{bmatrix} \begin{bmatrix} \Re(\mathbf{x}) \\ \Im(\mathbf{x}) \end{bmatrix} + \begin{bmatrix} \Re(\mathbf{n}) \\ \Im(\mathbf{n}) \end{bmatrix}. \tag{2}$$

The dimension of $\mathbf{H}_r$ becomes $\mathfrak{n} \times \mathfrak{m} = 2N_t \times 2N_r$. This study adopted two channel models to evalute the proposed algorithm. The first is the time-correlated channel expressed by

$$\mathbf{H}_t = \sigma\mathbf{H}_{t-1} + (1-\sigma)\mathbf{H}_R, \tag{3}$$

where $\mathbf{H}_t$ and $\mathbf{H}_{t-1}$ are successive $N_r \times N_t$ channel matrices, σ is the time-correlated factor, $0 \leq \sigma \leq 1$, and $\mathbf{H}_R$ represent an $N_r \times N_t$ Rayleigh fading channel matrix of i.i.d $\mathcal{CN}(0,1)$. This model characterizes the correlation of successive channel matrices by the correlation value σ. The second is the practical system modelled by the QuaDRiGa [8], which is a geometry-based stochastic channel and can generate a 3D MIMO scenario as the mobile station (MS) moves along a track.

B. Lattice Reduction

Lattice is an infinite grid of discrete spaced points in a vector space. A complex lattice [9] is defined as

$$\mathcal{L} = \{t_1\mathbf{b}_1 + t_2\mathbf{b}_2 + ... + t_M\mathbf{b}_M \mid t_1...t_M \in \mathbb{G}\}, \tag{4}$$

$t = 2$
while $t \leq M$ **do**
  for $p = t-1, ..., 1$ **do**
    $\mu = \lceil \bar{\mathbf{R}}_{p,t} / \bar{\mathbf{R}}_{p,p} \rfloor$
    if $\mu \neq 0$ **then**
      $\bar{\mathbf{R}}_{1:p,t} \leftarrow \bar{\mathbf{R}}_{1:p,t} - \mu \bar{\mathbf{R}}_{1:p,p}$
      $\mathbf{T}_{:,t} \leftarrow \mathbf{T}_{:,t} - \mu \mathbf{T}_{:,p}$
    end if
  end for
  if $\delta \times |\bar{\mathbf{R}}_{t-1,t-1}|^2 > |\bar{\mathbf{R}}_{t,t}|^2 + |\bar{\mathbf{R}}_{t-1,t}|^2$ **then**
    swap columns $t-1$ and t in $\bar{\mathbf{R}}$ and $\mathbf{T}$
    calculate GR matrix $\Theta = \mathbf{G}(t-1, t)$
    $\bar{\mathbf{R}}_{t-1:t,t-1:N} \leftarrow \theta \bar{\mathbf{R}}_{t-1:t,t-1:N}$
    $\bar{\mathbf{Q}}_{:,t-1:t} \leftarrow \bar{\mathbf{Q}}_{:,t-1:t} \Theta^H$
    $t \leftarrow max\{t-1, 2\}$
  else
    $t \leftarrow t+1$
  end if
end while
Output: $\bar{\mathbf{Q}}, \bar{\mathbf{R}}, \mathbf{T}$ such that $\mathbf{H} = \bar{\mathbf{Q}}\bar{\mathbf{R}}$

where $\{\mathbf{b}_1, \mathbf{b}_2, ..., \mathbf{b}_M\}$ are the basis vectors and $\mathbb{G}$ denotes the Gaussian integer set, $\mathbb{G} = \mathbb{Z} + \mathbb{Z}j$. If two matrix $\mathbf{B}$ and $\mathbf{BT}$ span the same lattice, it means that $\mathbf{B}\mathbb{Z}^N = \mathbf{BT}\mathbb{Z}^N$ and thus $\mathbb{Z}^N = \mathbf{T}\mathbb{Z}^N$. $\mathbf{T}$ is an unimodular matrix, that is, $\mathbf{T}$ is invertible and the elements of $\mathbf{T}$ are Gaussian integers and $|det(\mathbf{T})| = 1$. Thus, the MIMO system can be represented as a lattice form as follows:

$$\mathbf{y} = \mathbf{h}_1 x_1 + \mathbf{h}_2 x_2 + ... + \mathbf{h}_{N_t} x_{N_t} + \mathbf{n}, \tag{5}$$

where $\mathbf{h}_1, \mathbf{h}_2, ..., \mathbf{h}_{N_t}$ are the columns of $\mathbf{H}$. The reduced channel matrix can be written as

$$\hat{\mathbf{H}} = \mathbf{HT}, \tag{6}$$

where $\mathbf{H}$ is the correlated channel matrix, $\mathbf{T}$ is the unimodular matrix derived by the LR algorithm, and $\hat{\mathbf{H}}$ is the lattice reduced channel matrix.

Lenstra-Lenstra-Lovsz (LLL) LR [10] is the generic lattice reduction algorithm and it can be reformulated as the QR decomposed form in **Algorithm 1**. The LLLLR algorithm uses two constraints to derve the unimodular matrix $\mathbf{T}$. The first is the size reduction

$$\frac{1}{2} \times |\bar{\mathbf{R}}_{k,k}| \geq |\bar{\mathbf{R}}_{k,t}| \quad for\ 1 \leq k < t \leq M. \tag{7}$$

and LLL reduction as

$$\begin{aligned} &\delta \times |\bar{\mathbf{R}}_{t-1,t-1}|^2 \leq |\bar{\mathbf{R}}_{t,t}|^2 + |\bar{\mathbf{R}}_{t-1,t}|^2 \\ &for\ 2 \leq t \leq M, 0 < \delta \leq 1. \end{aligned} \tag{8}$$

The processing of LLL LR algorithm starts from column $t = 2$ based on the size reduction and LLL reduction and every columns operation is recorded in the matrix $\mathbf{T}$.

To apply the LR preprocessing for MIMO detection, we can reformulate the MIMO channel after LR as

$$\mathbf{y} = \mathbf{Hx} + \mathbf{n} = \mathbf{HTT}^{-1}\mathbf{x} + \mathbf{n} = \hat{\mathbf{H}}\mathbf{z} + \mathbf{n}, \tag{9}$$

where $\hat{\mathbf{H}} = \mathbf{HT}$ represents the lattice-reduced matrix and $\mathbf{z} = \mathbf{T}^{-1}\mathbf{x}$ represents the symbol vector in the lattice domain. The signal $\mathbf{x}$ belongs to Ω^{N_t} because of the QAM mapping, so we convert $\mathbf{x}$ to the domain of $\mathbb{G}^{N_t}$ for the LR calculation in Eq. (9) by shifting and scaling operations. For a transmitted M-QAM symbol, the transformed signal becomes $\bar{\mathbf{x}} = \mathbf{x}/a - \frac{\mathbf{1}}{\mathbf{2}}(1+j)$, where $a = \sqrt{\frac{6}{(M-1)}}$ is the power normalization factor of M-QAM. Then, the signal model is reformulated by

$$\mathbf{y} = \mathbf{Hx} + \mathbf{n} = \mathbf{H}\{\bar{\mathbf{x}} + \frac{\mathbf{1}}{\mathbf{2}}(1+j)\}a + \mathbf{n}. \tag{10}$$

After dividing a (scaling) and subtracting $\mathbf{H}\frac{\mathbf{1}}{\mathbf{2}}(1+j)$ (shifting) on both sides, the signal model becomes

$$\hat{\mathbf{y}} = \frac{1}{a}\mathbf{y} - \mathbf{H}\frac{\mathbf{1}}{\mathbf{2}}(1+j) = \mathbf{H}\bar{\mathbf{x}} + \frac{1}{a}\mathbf{n}. \tag{11}$$

This signal model is equivalent to the original MIMO system in Eq. (1) except that the transmission symbol vector is in bounded continuous integers and the noise becomes $\frac{1}{a}$. After LR, the signal model for the LR-aided detector is written as

$$\hat{\mathbf{y}} = \hat{\mathbf{H}}\bar{\mathbf{z}} + \frac{1}{a}\mathbf{n}, \tag{12}$$

where $\hat{\mathbf{H}}$ is the reduced matrix and $\bar{\mathbf{z}} = \mathbf{T}^{-1}\bar{\mathbf{x}}$ is the transmit symbol vector in the lattice domain. Then, the lattice-reduction-aided maximum likelihood (ML) detection becomes

$$\hat{\mathbf{z}} = \underset{z \in \Omega^{N_t}}{\arg\min} |\hat{\mathbf{y}} - \hat{\mathbf{H}}\mathbf{z}|. \tag{13}$$

Afterwards, the function $round()$ must be used to slice $\mathbf{T}\hat{\mathbf{z}}$ to the closest point of $\{\bar{\mathbf{x}}\}$ as the detection result as follows:

$$\hat{\mathbf{x}} = \{round(\mathbf{T}\hat{\mathbf{z}}) + \frac{\mathbf{1}}{\mathbf{2}}(1+j)\}a. \tag{14}$$

III. Deep Learning Model for Lattice Reduction

A. Design Issues of Deep Learning for Lattice Reduction

This work aims to design the DL-based LR-aided MIMO preprocessing for the time-varying channel, in which the data association exists between channel $\mathbf{H}_t$ and $\mathbf{H}_{t-1}$. From Eq. (6), the lattice-reduced channel matrix is the product of the original channel matrix and the unimodular matrix. Therefore, if $\mathbf{H}_t$ and $\mathbf{H}_{t-1}$ have the data association, then so do $\hat{\mathbf{H}}_t$ and $\hat{\mathbf{H}}_{t-1}$. Thus, $\mathbf{T}_t$ and $\mathbf{T}_{t-1}$ may also have the data association. The temporal relevancy can be used to predict the unimodular matrix $\mathbf{T}$ by the LR model. In this paper, the channel matrix $\mathbf{H}$ is represented in a real model with the same number of antennas in the transceiver and receiver, that is, $\mathbf{H} \in \mathbb{R}^{\mathcal{M} \times \mathcal{M}}, \mathbf{T} \in \mathbb{Z}^{\mathcal{M} \times \mathcal{M}}$ and $\mathcal{M} = 2N_t$. Because $\mathbf{T}$ is invertible and unimodular with all integer entries and $|det(\mathbf{T})| = 1$ and finding the unimodular matrix is an NP-hard problem [11], the DL model is incapable of accomplishing the LR algorithm directly. Therefore, we proposed a path matrix $\mathbf{P}$ by the DL model, thereby obtaining $\mathbf{T}$ indirectly. The path matrix $\mathbf{P}$ is represented as

$$\begin{aligned} &\mathbf{T}_t = \mathbf{T}_{t-1}\mathbf{P}, \\ &\mathbf{P} = (\mathbf{T}_{t-1})^{-1}\mathbf{T}_t = \mathbf{I}_{N_t} \cdot \mathbf{P}'_1\mathbf{P}'_2 \ldots \mathbf{P}'_I, \end{aligned} \tag{15}$$

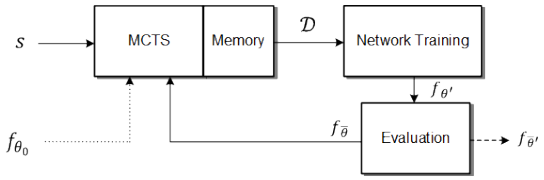

Fig. 1: Architecture of AlphaGo Zero.

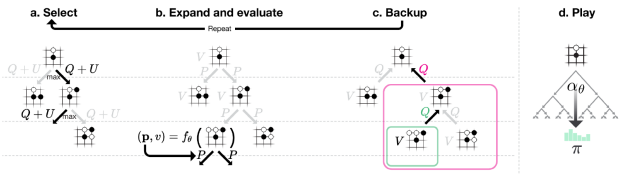

Fig. 2: Monte-Carlo Tree Search in AlphaGo Zero, from [6].

where $\mathbf{P}'_i$ is the step matrix for $i = 1, 2, ..., I$. Each step matrix is the function of (o, x, y), and a step matrix is expressed as

$$\mathbf{P}'_i = \mathbf{I}(o, x, y), \tag{16}$$

where o is the operator similar to μ in the LLL LR algorithm, and $o \in \mathbf{o}, \mathbf{o} = [\pm 1, \pm 2, \pm 4, \pm 8, \pm 16, swap, none]$. (x, y) are the column and row indices of the operator o in $\mathbf{P}'_i$. For example, if $\mathbf{I}(o, x, y) = \mathbf{I}(-2, 3, 4)$, then

$$\mathbf{P}'_i = \begin{bmatrix} 1 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 \\ 0 & 0 & 1 & 0 \\ 0 & 0 & -2 & 1 \end{bmatrix} \tag{17}$$

Therefore, the unimodular matrix $\mathbf{T}_t$ can be obtained from $\mathbf{T}_{t-1}$ by the path matrix $\mathbf{P}$ consisting of step matrices $\mathbf{P}'_i$. Then, we can use step matrices $\mathbf{P}'_i$ in Eq. (16) to construct the DL model, which predicts integers o, x, and y for constructing path matrix $\mathbf{P}$ and $\mathbf{T}$ by Eq. (15). Because the defined lattice reduction DL model is similar to the Go game, this study proposed to adopt the DL architecture of the AlphaGo Zero to solve this complex decision problem.

B. AlphaGo Zero

AlphaGo Zero is a version of DeepMind's Go software AlphaGo [12] with the reinforcement learning technique [13] and it can be roughly divided into three stages of Monte-Carlo tree search (MCTS), neural network, and evaluation. Figure 1 shows the architecture of AlphaGo Zero, s is the state of the Go board, f_{θ_0} is the neural network with initial weights, $\mathcal{D}$ is the training dataset, $f_{\theta'}$ is the neural network with updated weights, $f_{\bar{\theta}}$ is the neural network with updated weights after evaluation, and $f_{\bar{\theta}'}$ is the final network after all iterations.

1) Monte-Carlo Tree Search

MCTS can be regarded as a form of self-play reinforcement learning. It focuses on the analysis of the most promising Go move, which is called policy. The goal of MCTS is to improve the selection policy of the Go move. MCTS in AlphaGo Zero is based on many "playouts", and a playout is a Go game. Each gain is played out to the very end by choosing Go moves through a selecting equation. Then, the final game result of each playout is used to weight the tree nodes, so that the better nodes are more likely to be chosen in the future. Additionally, MCTS is a tree-like structure consisting of many nodes, and each node stores several weights including a visit count $\mathcal{N}(s, a)$, a prior probability $\mathcal{P}(s, a)$, and an action-value $\mathcal{Q}(s, a)$, where s is the board state and a is the Go move. The process of MCTS in AlphaGo Zero is shown in Figure 2. The input of MCTS is the state of the game board, which is a 19×19 image with the position of Go stones. The output is the Go move policy, which is represented by a vector with the size $N \times 1$ with $N = 19 \times 19 + 1$ all possible Go moves on the board and "pass" moves. The neural network $f_{\bar{\theta}}$ guides the MCTS simulation and is composed of four steps. An iteration of running **step a** to **step c** is called a simulation, and the MCTS simulation is repeated K times in total ($K = 1600$). Then, **step d** will calculate the Go move policy.

a. Select

This step selects the child node down to the leaf node N_L continuously through the selecting equation starting from the root node. The root node is the current game state and the leaf node is the state after playing Go moves. The selecting equation is expressed as

$$a_i = \arg\max_{a_n} \{\mathcal{Q}(s_i, a_n) + \mathcal{U}(s_i, a_n)\}, i \leq N_L, n = 1, 2, ..., N, \tag{18}$$

where a_i is the selected node in the i-th layer of the tree, a_n are the nodes that represente all available Go moves. $\mathcal{Q}(s_i, a_n)$ is action-value with game state s_i and Go move a_n, $\mathcal{Q}(s_i, a_n) = \mathcal{W}(s_i, a_n) / \mathcal{N}(s_i, a_n)$, where $\mathcal{W}(s_i, a_n)$ is the accumulation of the evaluation value from the neural network and $\mathcal{N}(s_i, a_n)$ is the visit count. $\mathcal{U}(s_i, a_n)$ is the exploration weight with game state s_i and Go move a_n, $\mathcal{U}(s_i, a_n) = \mathcal{C} \cdot \mathcal{P}(s_i, a_n) / 1 + \mathcal{N}(s_i, a_n)$, where $\mathcal{C}$ is the exploration constant ($\mathcal{C} = 5$) and $\mathcal{P}(s_i, a_n)$ is the prior probability from the neural network.

b. Expand and Evaluate Afterwards, the search tree is expanded by the neural network. The leaf node s_{N_L} becomes the input of the neural network $f_{\bar{\theta}}$, and the network generates output move probabilities $\mathbf{p}$ and evaluation value v to expand the search tree. Then, the weights of the expanded node are initialized as

$$\begin{aligned} \mathcal{Q}(s_{N_L+1}, a_n) &= 0, \\ \mathcal{W}(s_{N_L+1}, a_n) &= 0, \\ \mathcal{N}(s_{N_L+1}, a_n) &= 0, \\ \mathcal{P}(s_{N_L+1}, a_n) &= p_{a_n}, \end{aligned} \tag{19}$$

where $p_{a_n} \in \mathbf{p}$ and p_{a_n} is the probability of move a_n. To ensure that all nodes be visited, the prior probability in the root node expansion is added with the Dirichlet noise as follows:

$$\mathcal{P}(s_1, a_n) = (1 - \epsilon) p_{a_n} + \epsilon \eta, \tag{20}$$

where ϵ is a constant ($\epsilon = 0.25$), and η is the Dirichlet noise, $\eta \sim \texttt{Dir}(0.03)$.

c. Backup

In this step, to make a better result in the next round selection, the parent nodes of the expanded node in **step b** are updated. The update function is expressed as

$$\begin{aligned}\mathcal{W}(s_i,a_n) &= \mathcal{W}(s_i,a_n)+v,\\ \mathcal{N}(s_i,a_n) &= \mathcal{N}(s_i,a_n)+1,\\ \mathcal{Q}(s_i,a_n) &= \mathcal{W}(s_i,a_n)\,/\,\mathcal{N}(s_i,a_n),\end{aligned} \tag{21}$$

where v is the evaluation value generated by the neural network $f_{\bar{\theta}}$ in **step b**.

d. Play

After K times simulations, the final output, the Go move policy, is calculated as

$$\boldsymbol{\pi} = \frac{\mathcal{N}(s_1,a_i)^{\frac{1}{\tau}}}{\sum_{n=1}^{N}\mathcal{N}(s_1,a_n)}, \forall i \in \{1,2,...,N\}, \tag{22}$$

where τ is the temperature parameter ($\tau = 1$). In the end, the results of MCTS are stored as training dataset $\mathcal{D}$ in the form of $(s_t, \boldsymbol{\pi}_t, z_t)$, where s_t is the state of the board at time t, $\boldsymbol{\pi}_t$ is the output policy for state s_t, and z_t is the winner from the current player's perspective at time t.

2) Neural Network

The input of the neural network is an image stack with size $19\times19\times17$, where 17 represents the number of feature planes. 8 of 17 feature planes, X_t, represent the current player's Go stones. $X_t = 1$ if the intersection i has a stone of the player at time t; $X_t = 0$ if the intersection has an opponent stone or is empty; if $t < 0$, X_t is also written as 0. Another 8 of 17 feature planes, Y_t, indicate the corresponding features for the opponent's Go stones. And the final feature plane, C, denotes the stone color to play, $C = 1$ if black is to play; $C = 0$ if white is to play. Thus, the input of the neural network $s_t = [X_t, Y_t, X_{t-1}, Y_{t-1}, ..., X_{t-7}, Y_{t-7}, C]$. The outputs to the neural network are an $N \times 1$ vector of the policy $\mathbf{p}_{\texttt{pred}}$ and a scalar of the evaluation value $v_{\texttt{pred}}$ corresponding to the MCTS results $\boldsymbol{\pi}$ and z, respectively.

IV. Proposed DL-Based LR-Aided MIMO System

A. Proposed Deep Learning Based Lattice Reduction

Figure 3 shows the architecture of the proposed deep learning-based lattice reduction. The proposed algorithm can be divided into offline and online schemes. In the offline scheme, the proposed algorithm architecture is referred to AlphaGo with similar neural network and MCTS model. Then, the trained neural network $f_{\bar{\theta}'}$ is used in the online scheme. In the online scheme, we adopted the MCTS model with the trained neural network to obtain step matrices $\mathbf{P}'_i$, which can be combined into the path matrix $\mathbf{P}$. Finally, we can obtain the unimodular matrix $\mathbf{T}_t$ through the path matrix. $\mathbf{S}$ is the product of the channel matrix $\mathbf{H}$ and the step matrix, and $\mathbf{B}$ is the unimodular matrix $\mathbf{T}$.

To apply AlphaGo Zero to the DL-based, the winning of a game is defined by channel orthogonality as follows:

$$O = \frac{\sum(|\widetilde{\mathbf{S}}|_{\text{diag}})}{\sum(|\widetilde{\mathbf{S}}|_{\text{off-diag}})}, \tag{23}$$

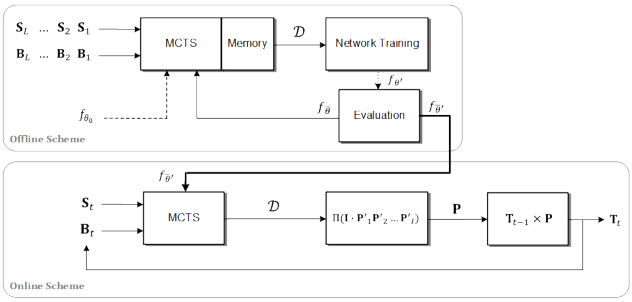

Fig. 3: The proposed architecture of DL-based LR.

where $\widetilde{\mathbf{S}}$ is the Gram matrix of $\mathbf{S}$. If the channel orthogonality is improved, it means the game wins. The following two inequalities are used to determine whether the orthogonality improves or not.

$$O_I > \lambda_O \text{ or } d > \lambda_d, \tag{24}$$

where O_I is the orthogonality after DLLR (orthogonality at step I), λ_O is the orthogonality threshold (λ_O = 10). d is the difference between O_I and O_0 (O_0 is the orthogonality of the original channel), and λ_d is the difference threshold (λ_d = 2). The action of the lattice reduction is defined as the step matrix associated with the operator and operating columns (o, x, y) in Eq. (16) and the number of actions N is

$$N = (10 \times \mathcal{M} \times (\mathcal{M}-1)) + (1 \times \mathcal{M} \times (\mathcal{M}-1)) + 1. \tag{25}$$

1) Offline Scheme

The offline scheme aims to train the DL model in Figure 3. The training process includes MCTS model, network training model, and evaluation model.

A. MCTS Model Figure 4 shows the architecture of the MCTS model in DLLR. The inputs of the MCTS are $\mathbf{S}$ and $\mathbf{B}$. $\mathbf{S}$ is the state matrix, which can be expressed by

$$\mathbf{S}_{l,i} = \mathbf{S}_{l,i-1} \times \mathbf{P}'_{l,i-1}, l = 1,2,...,L, i = 2,3,...,I, \tag{26}$$

where the initial $\mathbf{S}_{l,1} = \mathbf{H}_l$, $\mathbf{P}'_{l,1} = \mathbf{I}$. L denotes the channel number, and I is the step limit. The other input $\mathbf{B}$ is the bias matrix, which is the previous unimodular matrix

$$\mathbf{B}_l = \mathbf{T}_{l-1}, l = 1,2,...,L, \tag{27}$$

where the initial $\mathbf{T}_0$ is set to be $\mathbf{I}$. This bias matrix is used to find out the temporal features. The output of the MCTS simulation is a group of training data, which includes the state matrix $\mathbf{S}_{l,i}$, bias matrix $\mathbf{B}_l$, the policy $\boldsymbol{\pi}_{l,i}$ for the state $\mathbf{S}_{l,i}$, and the orthogonality improvement z_l. The former $\mathbf{S}_{l,i}$ and $\mathbf{B}_l$ are the aforementioned input matrices, and the latter policy $\boldsymbol{\pi}_{l,i}$ is the result of the tree search for state $\mathbf{S}_{l,i}$. z_l indicates whether the channel orthogonality is improved ($z_l = 1$) or not ($z_l = 0$), and it is only generated at the last step I. In addition, z_l of the training data from step 1 to step $I-1$ is equal to z_l at step I. Then, the data are stored as training dataset $\mathcal{D}$ for the network model. When the data is stored, the policy $\boldsymbol{\pi}_{l,i}$ is placed into the matrix operation at the same time. In

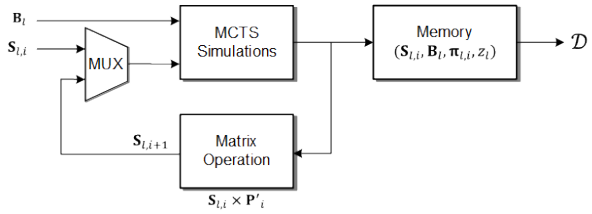

Fig. 4: Architecture of MCTS in DLLR.

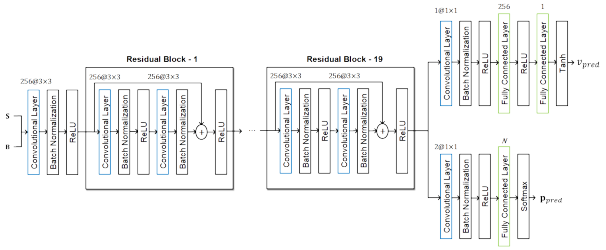

Fig. 5: Architecture of neural network in DLLR.

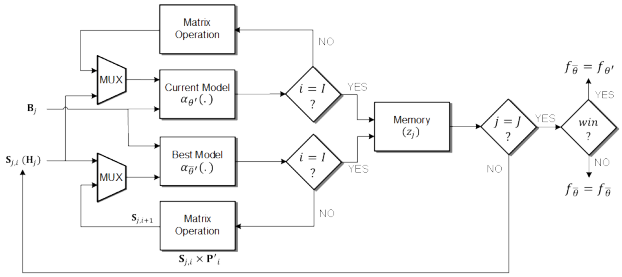

Fig. 6: Architecture of evaluation in DLLR.

matrix operation, we firstly transform $\boldsymbol{\pi}_{l,i}$ into step matrix $\mathbf{P}'_i$ as follows:

$$(o, x, y)_{\max} = a_{\max} = \max\{\boldsymbol{\pi}_{l,i}\}, \tag{28}$$

where $a_{\max}$ is the best action in $\boldsymbol{\pi}_{l,i}$ and $(o, x, y)_{\max}$ performs the column operations for the best action $a_{\max}$. Then, we can obtain the step matrix $\mathbf{P}'_i$ through Eq. (16). Finally, the input of the next step are generated as $\mathbf{S}_{l,i+1} = \mathbf{S}_{l,i} \times \mathbf{P}'_i$.

B. Network Training Model

Figure 5 shows the neural network architecture in DLLR. The DLLR network has two inputs, $\mathbf{S}$ and $\mathbf{B}$ in dataset $\mathcal{D}$. Then, $\boldsymbol{\pi}$ and z in dataset $\mathcal{D}$ are the labels for the neural network output $\mathbf{p}_{\text{pred}}$ and v_{pred}, respectively. $\mathbf{p}_{\text{pred}}$ is an $N \times 1$ vector that denotes the probability of actions, and v_{pred} is a scalar that denotes the probability of improving the orthogonality. We used the same loss function as that in the AlphaGo Zero. The Adam optimizer [14] was used to update all trainable parameters (weights) θ by

$$\begin{aligned} g_r &= \nabla_\theta \Phi \\ m_r &= \beta_1 m_{r-1} + (1-\beta_1) g_r \\ v_r &= \beta_2 v_{r-1} + (1-\beta_2) g_r^2 \\ \hat{m}_r &= \frac{m_r}{1-\beta_1^r} \\ \hat{v}_r &= \frac{v_r}{1-\beta_2^r} \\ \theta' &= \theta - \frac{\rho}{\sqrt{\hat{v}_r} + \epsilon} \hat{m}_r, \end{aligned} \tag{29}$$

where r is an iteration index, g_r is a gradient element, Φ denotes the loss function. m_r is the exponential moving averages of the gradient, v_r is the squared gradient, $\beta_1, \beta_2 \in [0, 1)$ are the hyper-parameters that control the exponential decay rates of these moving averages. ($\beta_1 = 0.9, \beta_2 = 0.999$). $\hat{m}_r$ and $\hat{v}_r$ are the bias corrections. θ' denotes the updated weights of the network, ρ is a learning rate ($\rho = 0.1$), and ϵ is a constant that avoids divisor by zero ($\epsilon = 10^{-7}$).

C. Evaluation Model

The evaluation is required to ensure the quality of training data for the DLLR. Figure 6 illustrates the architecture of the evaluation in the DLLR. We evaluated the current network f'_θ through the best network $f_{\bar{\theta}}$ at every checkpoint. $\mathbf{S}_{j,i}$ and $\mathbf{B}_j$ are inputs of the models of α'_θ and $\alpha_{\bar{\theta}}$, and the models operates for I steps to derive the results. Then, we determined the winner between the current network f'_θ and the best network $f_{\bar{\theta}}$, the winner z_j is represented as

$$z_j = \begin{cases} 1, & O_{I,\text{current}} > O_{I,\text{best}} \text{ or } d_{\text{current}} > d_{\text{best}}. \\ 0, & \text{otherwise.} \end{cases} \tag{30}$$

where $O_{I,\text{current}}$ and $O_{I,\text{best}}$ denote the orthogonality of the current network and the best network at step I, respectively, and d_{current} and d_{best} denote the differences of the current network and the best network, respectively. In addition, $d_{\text{current}} = O_{I,\text{current}} - O_{0,\text{current}}$ and $d_{\text{best}} = O_{I,\text{best}} - O_{0,\text{best}}$. After evaluating all input evaluation channels, we calculated the winning ratio Z

$$Z = \frac{\sum z_j|_{z_j=1}}{J}, \tag{31}$$

where J is the number of channels. The following inequality is used to determine whether the best network is updated from the current network or not

$$Z > \lambda_Z, \tag{32}$$

where λ_Z is the threshold of the winning rate ($\lambda_Z = 0.55$). If Z is greater than the threshold, we update the current network to the latest best network. Then, the best network is adopted in the next iteration of the MCTS model.

Algorithm 2 shows the offline algorithm. At the beginning, $\mathbf{T}$ is generated by the LLLLR algorithm (Line 1), as shown in **Algorithm 1**. Then, Line 2 to Line 5 prepare the input data for the MCTS model and T is the channel number. Line 6 splits the data into the training set and the evaluation set. Line 7 to Line 14 are the main process of DLLR. We initial $\bar{\theta}$ in Line 7, where θ_0 is generated randomly. R is the number of iterations. The MCTS model generates the training dataset $\mathcal{D}$ in Line 9, and the neural network is trained in Line 10. Then, we evaluate the networks at every checkpoint (Line 11

Algorithm 2 Deep Learning-based Lattice Reduction (Offline Scheme)

Input: $\mathbf{H}, T, R$
1: Generate $\mathbf{T} = LLL(\mathbf{H})$
2: **for** $t = 1, ..., T$ **do**
3: $\quad \mathbf{S}_t = \mathbf{H}_t$
4: $\quad \mathbf{B}_t = \mathbf{T}_{t-1}$
5: **end for**
6: Split $(\mathbf{S}, \mathbf{B})$ to $(\mathbf{S}_{\text{train}}, \mathbf{S}_{\text{eval}}, \mathbf{B}_{\text{train}}, \mathbf{B}_{\text{eval}})$
7: Initial $\bar{\theta} = \theta_0$
8: **for** $r = 1, ..., R$ **do**
9: $\quad$ Generate $\mathcal{D} = \alpha_\theta(\mathbf{S}_{\text{train}}, \mathbf{B}_{\text{train}})$
10: $\quad$ Calculate $(\mathbf{p}, v) = f_{\bar{\theta}}(\mathcal{D})$

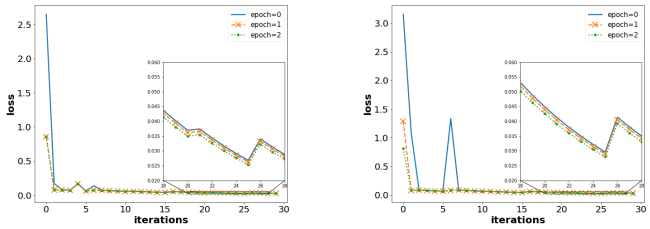
14: **end for**
15: $\bar{\theta}' = \bar{\theta}$
Output: $\bar{\theta}'$

to Line 13) of every 5 iterations. Finally, the final best network weights come out after running all iterations (Line 15).

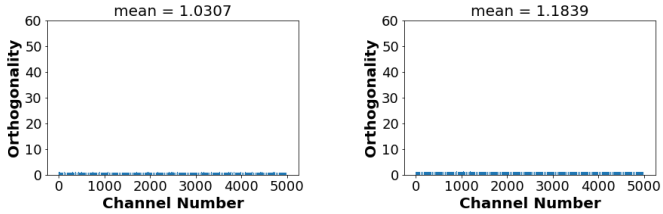
2) Online Scheme After the offline scheme, the best weights of the neural network $\bar{\theta}'$ is used in the online scheme. Figure 3 shows the online scheme architecture and **Algorithm 3** shows the the online processing algorithm. Firstly, we initial $\mathbf{T}_0$ and set the input $\mathbf{S}_t$ and $\mathbf{B}_t$ (line 1 $\sim$ line 4). The MCTS model with the weights is denoted as $\alpha'_{\bar{\theta}}$, and it will output the step matrices $\mathbf{P}'_i$ (line 5 $\sim$ line 6). Then, the path matrix $\mathbf{P}$ is generated by multiplying those step matrices (line 7). Finally, multiplying $\mathbf{T}_{t-1}$ and path matrix $\mathbf{P}$ can get the expected unimodular matrix $\mathbf{T}_t$ (line 8), where $\mathbf{T}_{t-1}$ is $\mathbf{B}_t$.



Algorithm 3 Deep Learning-based Lattice Reduction (Online Scheme)

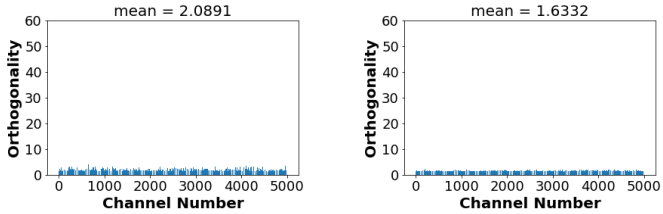
Input: $\mathbf{H}, T, \bar{\theta}'$
1: Initial $\mathbf{T}_0 = \mathbf{I}$
2: **for** $t = 1, ..., T$ **do**
3: $\quad \mathbf{S}_t = \mathbf{H}_t$
4: $\quad \mathbf{B}_t = \mathbf{T}_{t-1}$
5: $\quad$ Generate $\mathcal{D} = \alpha_{\bar{\theta}'}(\mathbf{S}_t, \mathbf{B}_t)$
6: $\quad$ Transform $\boldsymbol{\pi}$ to $\mathbf{P}'$
7: $\quad$ Calculate $\mathbf{P} = \mathbf{P}'_1 \mathbf{P}'_2 \ ... \ \mathbf{P}'_I$
8: $\quad \mathbf{T}_t = \mathbf{T}_{t-1} \times \mathbf{P}$
9: **end for**
Output: $\mathbf{T}$

V. Simulation and Analysis Results



A. Simulation Environments

This study considered the MIMO system with $N_t = N_r = 4$. In the time-correlated channel, correlation factors of $\sigma = 0.2$ and $\sigma = 0.8$ were considered. For the QuaDRiGa channel, the mobile station moves along a 2000-meter random street track. The QuaDRiGa simulation scenario adopted mmMAGIC 3D urban micro-cell measured in Europe. This scenario is for typical terrestrial pico-base stations deployed below rooftops in densely populated urban areas. The number of cluster N_{cl} in the scenario is 3 and the number of subpaths N_{path} in each cluster is 20.

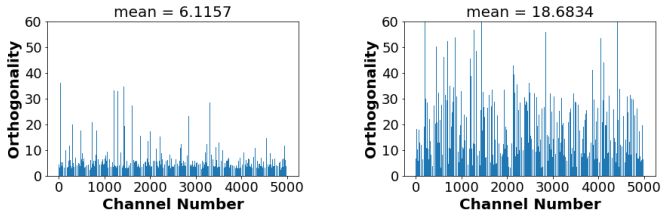


(a) (b)

Fig. 7: Convergence curves of training loss for the time-correlated factors of (a) $\sigma = 0.8$ and (b) $\sigma = 0.2$.

(a) (b)

Fig. 8: Orthogonality of the original channels with time-correlated factors of (a) $\sigma = 0.8$ and (b) $\sigma = 0.2$



(a) (b)

Fig. 9: Orthogonality of the LLLLR-reduced channels with time-correlated factors of (a) $\sigma = 0.8$ and $\sigma = 0.2$.

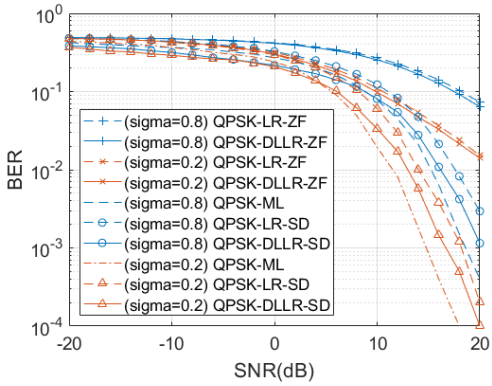
In the offline scheme, we use the number of iterations $R = \{25, 30\}$ to train the system for $\sigma = 0.2$ and $\sigma = 0.8$, respectively. Thresholds of the orthogonality λ_O and difference λ_d are 10 and 2, respectively. The total channel number T is 20000, and the channel number per iteration L is 10. In the MCTS model, we adopt the simulation times $K = \{100, 150\}$ and step limit $I = \{15, 20\}$ for $\sigma = 0.2$ and $\sigma = 0.8$, respectively. In the network training, epoch $E = 3$, batch size $B = 32$, and learning rate $\rho = 0.1$ were used. In the evaluation model, the input channel number J is 20, the checkpoint is every 5 iterations, and the threshold of the winning rate $\lambda_Z = 0.55$.

B. Simulation Results of Time-Correlated Channel

Figure 7 shows the DLLR training loss in time-correlated factor $\sigma = 0.8$ and $\sigma = 0.2$ respectively. The step limit $I = 20$ and simulation times $K = 150$ were used in the simulation. We can see that the higher time-correlated channel model converges faster and the convergence results are better

(a) (b)

Fig. 10: Orthogonality of the DLLR-reduced channels with time-correlated factors of $\sigma = 0.8$ and $\sigma = 0.2$.



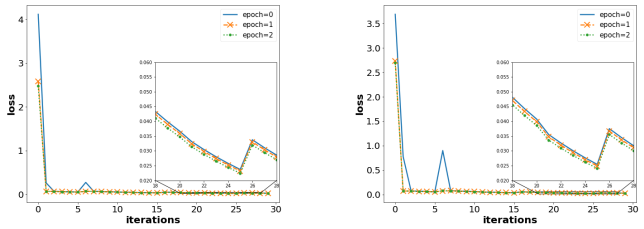


Fig. 11: BER performance curves of the LR-aided and DLLR-aided MIMO detectors with different time-correlated channels.

because the DLLR trains the data association in the time-varying channel. Thus, the higher temporal correlation resulted in better training results.

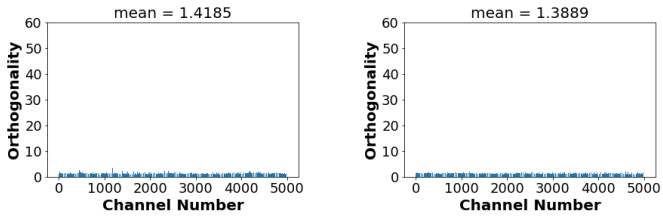

Figure 8 shows the channel orthogonality of the original channels with time-correlated factors of $\sigma = 0.8$ and $\sigma = 0.2$. Figure 9 plot the channel orthogonality of the reduced channels through the LLLLR algorithm. We can see that the lattice reduction algorithm (LLLLR) can effectively iincrease the channel orthogonalities under various correlation values. Figure 10 shows the channel orthogonality of the reduced channel through the DLLR algorithm. Compare with the channel orthogonalities of the original channel and the LLLLR-reduced channel, the DLLR can increase the channel orthogonality more effectively than the LLLLR algorithm. This result shows that the DLLR can figure out the data association between channels, so the model may be applied to the time-varying environment to increase the channel orthogonality. In Figure 10, the DLLR-reduced channel with $\sigma = 0.2$ has better orthogonality than that with $\sigma = 0.8$ because of the orthogonality $\lambda_O = 10$ and the threshold of the difference $\lambda_d = 2$. To speed up the DLLR calculations, the MCTS simulation can be stopped earlier if the channel orthogonality of the current step meets the winning condition. Therefore, the orthogonality of the channel with $\sigma = 0.8$ is lower than the one with $\sigma = 0.2$ because the MCTS simulations for $\sigma = 0.8$ was earlier stopped.

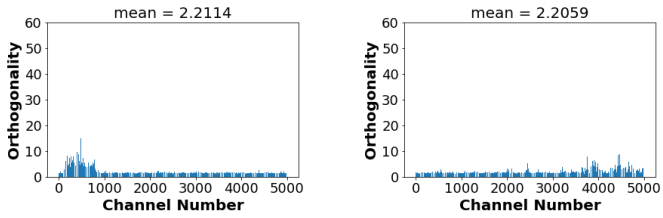
Figure 11 shows the BER performances of various lattice-

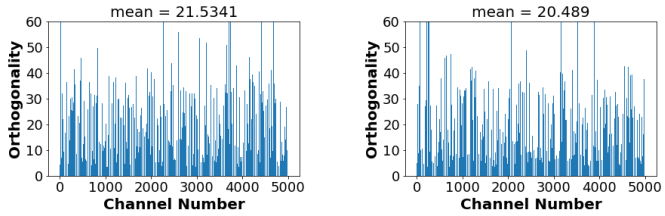


(a) (b)

Fig. 12: Convergence curves of training loss for the cluster numbers of (a) $N_{cl} = 3$ and (b) $N_{cl} = 6$.

(a) (b)

Fig. 13: Orthogonality of the original channels with (a) $N_{cl} = 3$ and (b) $N_{cl} = 6$ clusters.



(a) (b)

Fig. 14: Orthogonality of the LLLLR-reduced channels with $N_{cl} = 3$ and $N_{cl} = 6$ clusters.

reduction-aided detectors in the time-correlated MIMO channels with $\sigma = 0.8$ and $\sigma = 0.2$. We used QPSK modulation in the simulations and compared the performances of the LLLLR and DLLR algorithms. Since the channel orthogonality of the DLLR algorithm is better than the LLLLR algorithm, we can see that the BER of the DLLR is lower than that of the LLLLR. The DLLR algorithm enhances the channel orthogonality in the time-correlated channel model and obtains a better performance in the simulation of the MIMO system.

C. Simulation Results of QuaDRiGa Channel

Figure 12 shows the convergence curves of the DLLR training loss in the QuaDRiGa channel model with the number of the clusters $N_{cl} = 3$ and $N_{cl} = 6$, respectively. The training results of two cases are almost the same and their loss values finally approach 0.025. Figure 13 shows the channel orthogonaltiy of the QuaDRiGa channel models with $N_{cl} = 3$ and $N_{cl} = 6$. Figure 14 shows the channel orthogonality of the LLLLR-reduced channels in two cases. The orthogonality

(a) (b)

Fig. 15: Orthogonality in the reduced channel (DLLR) under different cluster numbers $N_{cl} = 3$ $N_{cl} = 6$.

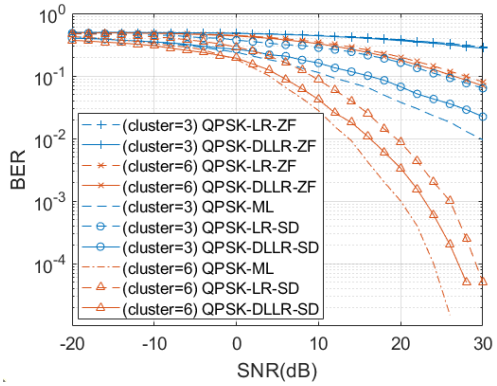


Fig. 16: BER performance curves of the LR-aided and DLLR-aided MIMO detectors with different cluster numbers in the QuaDRiGa channel.

of the LLLLR-reduced channel is better than that of the original channel similar to the time-correlated channel. Figure 15 shows the channel orthogonality of the DLLR-reduced channel in two cases. The DLLR can also improves the channel orthogonality significantly in the QuaDRiGa model. The data association between channels is trained by the DLLR algorithm and the number of clusters cause no difference in the training results of the DLLR algorithm. The primary reason is that the purpose of DLLR is to train the data association between channels. A larger cluster number represents the higher rank of the channel matrix, thus the DLLR algorithm causes no impact on the lattice reduced channels of different numbers of clusters. Figure 16 shows the BER performances of various lattice-reduction-aided detectors in the QuaDRiGa channels with $N_{cl} = 3$ and $N_{cl} = 6$ clusters. We also used QPSK modulation for the simulation and compared the performances of the LLLLR and DLLR algorithms with two cases. The orthogonality of the DLLR algorithm is better than that of the LLLLR algorithm, and the BER performances of the DLLR-aided detectors is also better than that of the LLLLR-aided detectors.

VI. Conclusion

This paper presents the lattice reduction preprocessing for time-correlated MIMO systems by the proposed AlphaGo-Based reinforcement learning. The offline and online trainining techniques were proposed to design the lattice reduction model that can adapt to the continous time-varying channel property. Final simulation results show that the proposed DLLR algorithm achieved much better performances than the original LR algorithm in terms of channel orthogonality and BER performance.

***Abstract*—Labeling onset and offset time and class information for audio files has always been a laborious task for sound event detection (SED) research. Therefore, it would be appealing to consider using strongly-labeled synthetic data and a large amount of unlabeled data when training a SED model. To utilize these data, previous research showed that mean-teacher based semi-supervised consistency training strategies could work with adversarial domain adaptation. However, the effectiveness has only been demonstrated in the domestic environment. In this work, we expand the scope of application to bird sound event detection in the natural environment. To achieve this, we established a synthetic strongly-labeled bird sound dataset consisting of 20 species. Then, we tuned the consistency training strategies and domain adaptation techniques that have been proven effective in the domestic environment to this new dataset. Our evaluation on the Eastern North American bird sound dataset resulted in an F1 score of >30%, which approaches the upper-bound performance that could be obtained when strongly-labeled data are assumed to be available. Thus, the strategies exhibit potential for advancing research in both indoor and outdoor SED.**

I. Introduction

Sound event detection (SED) aims to recognize and determine the onset and offset of different events in an audio recordings. Over the years, different deep learning models and training strategies have been developed to address SED in domestic and urban environments. The annual challenge on domestic SED held by DCASE has accelerated research in this area. However, primarily due to the lack of strongly-labeled data in these domains, it is still challenging to apply SED techniques in natural soundscapes. Particularly, bioacoustic SED in the animals' natural habitats [1][2] remains relatively under-explored.

The study of bird vocalization covers various tasks, including bird audio detection [3], bird sound classification and bird sound event detection. Bird audio detection focuses on the presence or absence of bird sound in an audio recording without classifying the specific bird type. Bird audio detection is crucial to applications such as automatic wildlife monitoring. In contrast, bird sound classification focuses on accurately categorizing the species or types of birds present in an audio recording, without necessarily determining the exact starting and ending times of individual sound events. In recent years, the advance of signal processing [4] and the development of deep learning models [5][6] have revolutionized the field of bird audio detection and bird sound classification. Finally, bird sound event detection not only requires classification of bird species, but also aims to determine the starting time and ending time of the bird calls.

In this research, our objective is to extend several methods and strategies which were proven useful in domestic SED [7] to outdoor environments, especially for detection of bird sound events. A pioneering work utilized the hidden Markov model [8] to detect the onset and offset of Zebra finch calls that were recorded in an indoor aviary. Later, as deep learning became popular, convolutional recurrrent neural networks (CRNNs) were constructed and tested on a synthetic bird sound dataset that contained 5 bird species [9]; the CRNNs were shown to be capable of detecting overlapping bird sounds. More recently, there has been an investigation on whether CRNNs can handle highly dense bird acoustic scenarios where up to 10 birds can call at the same time [10], with a set of strongly-labeled bird sound recordings from the Eastern North America (ENA) region [11]. In this paper, while we also adopted the ENA dataset for it contains full annotation of bird species, onsets, and offsets, we focused on semi-supervised learning (SSL) and domain adaptation strategies. Overall, we aimed to utilize a large amount of out-of-domain synthetic data together a limited amount of in-domain data that were either unlabeled or weakly labeled. The question we are asking is – can unlabeled data and synthetic data help for SED when strongly-labeled in-domain data are scarce?

The techniques used in this paper are based upon our previous research [12], which includes feature-pyramid convolutional recurrent neural network (FP-CRNN), pseudo-labeling (PL), mean-teacher (MT) models, and adversarial domain adaptation (ADA) [13]. The rest of this paper is organized as follows. Section II describes the methods we adopt to detect bird sound events. Section III introduces the datasets for this research and the pre-processing steps thereof. Afterwards, experiment details, results and discussion, and conclusions will be given in Sec. IV, V, and VI, respectively.

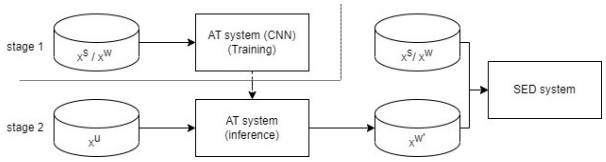

Fig. 1. Flow chart of pseudo-labeling techniques. x^{s}, x^{w}, x^{u} and $\mathrm{x}^{\mathrm{w}'}$ represent strongly-labeled, weakly-labeled, unlabeled, and pseudo weakly-labeled data, respectively. AT system is the model that needs to be trained to transform unlabeled data into pseudo weakly-labeled data.

II. Methods

In our previous work, several semi-supervised learning strategies and domain adaptation technique were employed to achieve outstanding performance in domestic SED using the DCASE 2020 Task4 dataset. In this section, we provide a thorough introduction to the model and the training strategies.

A. baseline deep learning model

FP-CRNN was chosen as our backbone model for this study. By combining the feature-pyramid component [14] with a basic CRNN model, the model is able to capture features at different scales. In detail, the FP-CRNN consists of seven CNN blocks, two layers of bidirectional gated recurrent units, a feature-pyramid component, and an attention layer which produces clip-level and frame-level predictions.

To utilize unlabeled and weakly-labeled data effectively, three semi-supervised learning strategies were adopted from our previous work — PL, mean teacher (MT) and shift-consistency mean teacher (SCMT) training, respectively. First, PL involves inferring weak labels for the originally unlabeled data by deploying an DNN-based audio-tagging (AT) system. The SED system is then trained with a combination of synthetic strongly-labeled and real weakly-labeled data. The dataflow of PL is shown in Fig. 1.

Secondly, the MT model consists of a student and a teacher model with the same structure. Parameters of the student model are updated through backpropagation, while parameters of the teacher model are set according to exponential moving average of the corresponding parameters of the student model, resulting in a slower but more stable way of updating the parameters. By calculating the mean square error (MSE) between the student and the teacher model, the consistency of the model can be enhanced.

Next, Fig. 2 illustrates an endeavor to incorporate shift consistency training (SCT) into the MT model, and the resulting system is referred to as the SCMT model. The integration can be achieved by jointly considering the MSE loss between the student model and the teacher model and a binary cross-entropy (BCE) loss between the frame-level predictions and the ground truth. The total loss function is expressed as follows,

$$\begin{aligned} L_{\mathrm{SCMT}} = & L_{wf,\mathrm{BCE}} + L_{sf,\mathrm{BCE}} + L_{st,\mathrm{BCE}} \\ & + r(t)(L'_{wt,\mathrm{MSE}} + L'_{wf,\mathrm{MSE}}) \\ & + r(t)(L'_{st,\mathrm{MSE}} + L'_{sf,\mathrm{MSE}}) \\ & + r(t)L_{st,\mathrm{MSE}} \end{aligned} \tag{1}$$

where $r(t) = e^{-5(1-t/T)^2}$ represents a ramp-up function of length T, subscripts w and s denote weakly-labeled outputs and strongly-labeled outputs, respectively, and f and t denote frequency shift and time shift, respectively.

Finally, we adopted two-stage ADA [15] technique to bridge the domain gap between synthetic data and real data. To cope with the ADA technique, the FP-CRNN was separated into a feature extractor and a label predictor. Besides, a CNN-based discriminator was trained to distinguish the input data as being synthetic or real. The following equation defines the learning objective of adversarial domain adaptation:

$$\begin{aligned} E(\theta_f, \theta_y, \theta_d) = & L_s(\theta_f, \theta_y) + L_w(\theta_f, \theta_y) \\ & - \lambda \cdot L_{D,\mathrm{BCE}}(\theta_f, \theta_y, \theta_d), \end{aligned} \tag{2}$$

where θ_f, θ_y and θ_d denote the parameters of feature extractor, label predictor and discriminator, respectively, λ denotes an adversarial loss weight, and $L_{D,\mathrm{BCE}}$ denotes the frame-level domain loss. The subscript w, s have the same meanings as in Eq. (1). Then, the following equations describe the adversarial training process,

$$(\hat{\theta}_f, \hat{\theta}_y) = \arg\min_{\theta_f, \theta_y} E(\theta_f, \theta_y, \hat{\theta}_d), \tag{3}$$

and

$$\hat{\theta}_d = \arg\max_{\theta_d} E(\hat{\theta}_f, \hat{\theta}_y, \theta_d). \tag{4}$$

III. Dataset

Experiments were conducted on multiple datasets. To begin with, a strongly-labeled dataset consisting of the sounds of Eastern North American (ENA) birds was retrieved. The dataset comprises 48 different bird species, totaling 385 minutes of audio recordings, and each recording is 5 minutes long. The dataset is marked with 16,052 annotations. In this research, we selected 20 bird species with more than 100 annotations as our identification targets.

Next, A strongly-labeled synthetic dataset comprising the same 20 bird species was created by mixing foreground bird calls with background environmental sounds. To obtain the foreground bird calls, audio clips of the 20 selected bird species were downloaded from xeno-canto, a website which allows bird observers to share wildlife sound recordings from around the world. Subsequently, bird calls contained in each audio clip were manually extracted in order to eliminate any silence between the calls. The duration of the resulting bird-sound segments ranges from 0.2 to 2 seconds.

Meanwhile, background environmental sound data were chosen from another bird sound dataset [16], which includes recordings captured in central and southern France and southern Spain. we specifically chose recordings without event labels to serve as our environmental sound clips. Finally, with the assistance of Scaper [17], a synthetic dataset with 3000 bird calls was generated, with fully-annotated event labels, and onset and offset times.

IV. Experiments

Selected details of the experiments are described in this section.

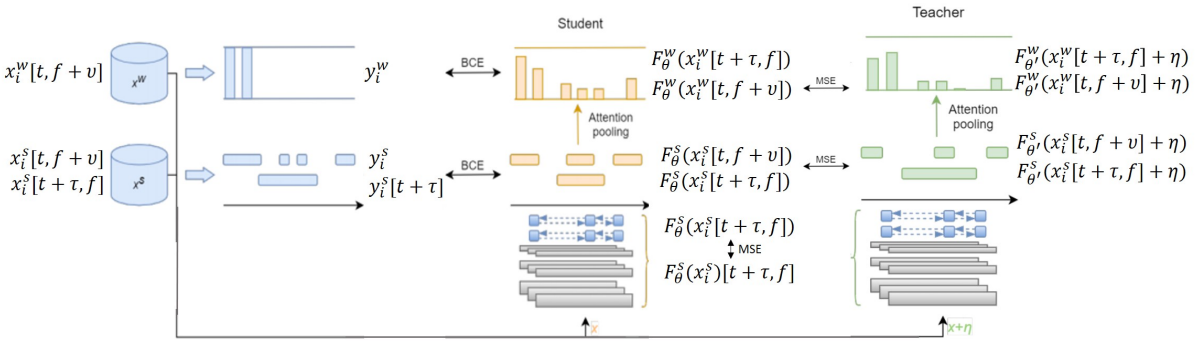

Fig. 2. the structure of shift consistency mean-teacher model. F_θ denotes a student model, $F_{\theta'}$ denotes a teacher model and the superscripts w and s denote clip-level and frame-level outputs from the model, respectively. f and t denote frequency and time, respectively; τ and ν denote the time and frequency shift, respectively. $\eta \sim \mathcal{N}(0, 0.5)$ denotes Gaussian noise that was added to the input of the teacher model.

A. Data Preprocessing and Feature Extraction

Each of the 5-minute recordings in the ENA dataset was partitioned into segments of 10 seconds with a hop length of 5 seconds. If the time interval between two events of the same class was shorter than 150 ms or if events of the same class overlapped in time, the events were merged into a single event. For each class, the shortest 10% of events were deleted unless they are 200 ms or longer. Table I summarizes the 20 bird species used in this research, along with the total number of annotations and the percentage of annotations with duration less than 200 ms after data pre-processing.

TABLE I
BIRD SPECIES IN THE ENA DATASET AFTER PRE-PROCESSING

Bird Species	Annotations	
	Total	Percentage (<0.2 sec)
AMCR	534	1.50
AMRE	274	0
BAWW	143	0
BCCH	1262	5.07
BGGN	320	1.25
BHCO	176	5.11

TUTI	885	1.12
WOTH	1826	0.43

Following the same settings as in our previous work [7], the audio files were first transformed into log-Mel spectrograms. The audio clips were first resampled to 32 kHz, and the window size, hop length, and the number of Mel bins were 2048, 255 and 128, respectively. Thus, the size of log-Mel spectrogram was fixed at 1255×128.

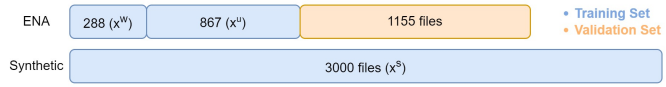

Fig. 3. Data splitting for training and validation. The superscripts w, u and s have the same meaning as in Fig. 2.

B. Other Configurations

The experiments were divided into several parts, and all of them used both the ENA dataset and the strongly-labeled synthetic dataset as training data. However, the role played by the ENA data could vary. In the first part, the ENA data was used as strongly labeled data, and the result will be reported in Sec. V.A to check the model's performance when trained on strongly-labeled and in-domain data. In subsequent parts of the experiments, we aimed to investigate whether the performance could be boosted via different training strategies when the out-of-domain synthetic data were strongly labeled while the in-domain ENA data were not. Thus, the ENA dataset was treated as unlabeled or weakly-labeled data; in other words, the class labels or the timing information were intentionally ignored. To achieve this, we split the ENA training data into two parts, 25% as weakly-labeled and 75% as unlabeled, and the data splitting scheme is illustrated in Figure 3.

To utilize the "unlabeled" ENA data, a pre-trained ResNet-based audio tagging system was fine-tuned for weak label generation [12]. This scheme is referred to as pseudo-labeling (PL) hereafter. As for implementing SCMT, the time shift and frequency shift were set to vary between -2.0 to 2.0 sec and -4 to 4 mel bins, respectively. During training, the Adam optimizer was adopted with the option of learning-rate adjustment.

V. RESULTS AND DISCUSSIONS

A. Evaluation of the baseline model on strongly-labeled ENA data and synthetic data

Table II shows the F1 scores (%) for the CRNN and FP-CRNN trained on strongly-labeled datasets. Both models were

effective to a certain extent, even when trained solely on out-of-domain synthetic data (SYN). It is worth noticing that basic CRNN model performed better than FP-CRNN when only trained on the ENA dataset. However, FP-CRNN performed better on synthetic-only and mixed dataset. The performance difference was probably due to data insufficiency in the ENA dataset for this part of the experiments. As FP-CRNN is a more complicated model than the basic CRNN, we speculate that it demands more data during the training phase to perform well.

TABLE II
F1 SCORE (%) COMPARISON OF BASELINE MODEL TRAINED WITH STRONGLY-LABELED ENA DATASET AND SYNTHETIC DATASET

Model	ENA	SYN	ENA+SYN
CRNN	30.81	13.49	39.30
FP-CRNN	22.75	14.01	43.44

B. Evaluation on models when using the ENA dataset as unlabeled or weakly-labeled data

In this part of the experiments, we simulated situations where strongly-labeled real training data were unavailable. Instead, we only had strongly-labeled synthetic data and unlabeled or weakly-labeled real data. Table III summarizes the F1 scores (%) for the situations in which all in-domain training data were unlabeled, or part of them were weakly labeled (see Fig. 3). Note that, the F1 score became higher when MT and SCMT strategies were adopted. Also, the performance further improved when accurate weak labels were provided. Note that 9 to 12% of net improvement in the three F1 scores could be obtained.

TABLE III
COMPARISON OF F1 SCORE (%) WITH DIFFERENT SEMI-SUPERVISED LEARNING (SSL) STRATEGIES

SSL Strategies	Unlabeled data	Weakly-labeled data
-	14.01	25.92
MT	16.92	26.39
SCMT	18.48	**27.84**

C. Evaluation on proposed semi-supervised learning strategies

Table IV indicates the F1(%) score before and after applying PL to the 867 unlabeled clips. Note that the performance consistently improved, and hence there seemed to be no conflict between MT or SCMT and PL.

TABLE IV
F1 SCORE(%) COMPARISON OF DIFFERENT MODELS BEFORE AND AFTER DOMAIN ADAPTATION

SSL Strategies	Before PL	After PL
-	25.92	26.34
MT	26.39	29.03
SCMT	27.84	**29.81**

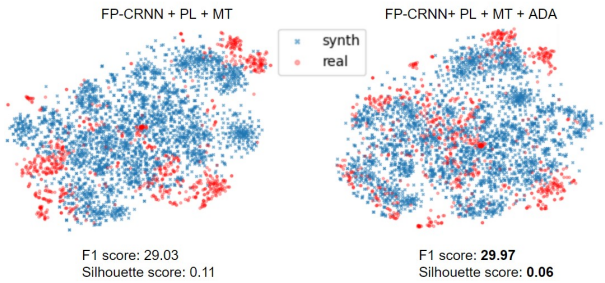

Fig. 4. Visualization of embedded features generated from a trained model before and after applying ADA .

D. Effectiveness of domain adaptation

TABLE V
F1 SCORE(%) COMPARISON BEFORE AND AFTER DOMAIN ADAPTATION

SSL Strategies	Before ADA	After ADA
-	25.92	26.97
PL	26.34	27.42
PL + MT	29.03	29.97
PL + SCMT	29.91	**30.72**

Finally, the performance of domain adaptation is summarized in Table V. Note that the F1 score consistently increased after applying the ADA technique, with the optimal score of 30.72% when the shift consistency, mean-teacher, pseudo-labeling, and adversarial adaptation strategies were all applied. Note that this F1 score approaches the CRNN score in Table II, 30.81%, that was obtained when in-domain strongly-labeled data were assumed to be available.

To quantify how well the ADA technique works, we calculated the silhouette score. Silhouette score ranges from -1 to 1, and a high score indicates high degree of separation between two clusters; in the present scenario, the two clusters are synthetic data and real data, respectively. Therefore, after we apply domain adaptation on our model, a low silhouette score is desired. Figure 4 shows a pair of t-SNE plots of the data before and after ADA was applied, and the corresponding silhouette scores are reported. Note that, in this particular combination of SSL strategies (PL+MT), the silhouette score was successfully decreased by ADA, which led to an increase of F1 score by approximately 1.0%. Thus, these results jointly show that domain adaptation can reduce the gap between synthetic data and real data, and the ADA technique could work with different combination of SSL strategies.

VI. CONCLUSIONS

In the present research, we created a synthetic dataset with 20 common bird species in the East Northern America region, and the synthetic data set was used with real data of the same bird species to test various sound event detection strategies. We demonstrate that all the strategies, including FP-CRNN, SCMT, PL, and ADA, could be applied jointly to improve the F1 score of sound event detection in this scenario, and

the improvement could be achieved whenever a new strategy is added. The present success shows that the models and training strategies previously designed for domestic sound event detection can now also be applied in an outdoor environment for bio-acoustic applications. In conclusion, through these experiments, we have shown that the model can be trained by supplying out-of-domain synthetic data and in-domain unlabeled and weakly-labeled data, and usage of these strategies is not limited to a single application scenario.

ACKNOWLEDGMENT

This research was supported by the National Science and Technology Council of Taiwan under grant No. 111-2634-F-002-023. Furthermore, we acknowledge the Xeno-canto community at www.xeno-canto.org for their valuable audio recordings used in our research.

***Abstract*—Remote photoplethysmography (rPPG) is a non-invasive technology that can be used to extract heart rate (HR) from video data. Video codecs are typically used for compressing video, which allows for efficient data storage, but could negatively impact the accuracy of HR estimation. To date, only limited number of studies investigate the impact of video codecs on rPPG-based HR estimation. In this paper, we present a comprehensive comparative evaluation of video codecs for rPPG-based HR estimation. Several factors being compared include video encoders, video containers, quality rate mode, and resolution. Experimental results using in-house dataset show that the lossy encoder like VP9 yield good performance nearly similar to the lossless counterparts. Additionally, the.avi container is preferable because it can contain all encoders tested except x265 (HEVC). Varying the resolution significantly affects the file size and accuracy of HR estimation. This study provides useful information for the creation of rPPG dataset and development of rPPG algorithm.**

I. Introduction

Heart rate (HR) monitoring is an important aspect of healthcare, sports, and fitness monitoring. Traditional HR monitoring methods involve direct contact with the skin, which can be uncomfortable and may cause skin irritation [1]. Remote photoplethysmography (rPPG) technology provides a noninvasive alternative to traditional methods by analyzing physiological signals from video data captured by cameras [2].

The use of rPPG-based HR estimation has gained significant attention in recent years [3]. To develop and evaluate rPPG algorithms, many researchers use publicly available datasets such as PURE [4], VIPL-HR [5], DEAP [6], COHFACE [7], MMSE-HR [8] and UBFC-Phys datasets [9]. These datasets differ in the way the data are stored. Some datasets are stored in sequences of PNG images with timestamps (e.g. PURE) while other datasets (e.g. VIPL-HR and UBFC-Phys) are stored in the form of videos. Large and diverse datasets are needed for fostering the development of accurate and reliable rPPG algorithms. However, creating datasets can be challenging due to the need for storing large amounts of video data and the lack of a guideline regarding the dataset storage format. In light of this, video codecs play a crucial role in reducing the size of video data and allowing efficient data storage and transmission [10]. Different video codecs use different algorithms and compression methods, resulting in varying levels of compression quality, which affects the accuracy of HR estimation. To date, however, there have been only few studies that investigate the impact of video codecs on rPPG-based heart rate estimation [10]–[12].

To address the above problem, in this paper, we present a comparative evaluation of different video codecs on rPPG-based HR estimation. Specifically, we compare the effects of video encoders, video containers, quality rate mode, and resolution to the accuracy of HR estimation. This paper aims to provide insights into the performance of different video codecs and their suitability for rPPG-based HR estimation.

The remainder of this paper is organized as follows. Section II describes the processing pipeline, video encodings, experimental setup, and performance metrics. Section III presents and discusses the impact of different video compressions, video containers, constant rate factor (CRF) values, resolution and scaling algorithms on the accuracy of rPPG-based HR estimation. Finally, conclusions are drawn in Section IV.

II. Methods

A. Processing Pipeline

The processing pipeline is illustrated in Fig. 1. It consists of three main blocks namely dataset recording, video making, and performance benchmarking. The dataset recording block is used to record in-house datasets from subjects and obtain the HR reference data using a pulse oximeter. These data will be used to make a video using several video encoders. In the performance benchmarking block, these videos will be evaluated using an rPPG algorithm to generate sequences of HR prediction and the error will be calculated using reference data recorded in the dataset recording block. The data processing pipeline is implemented in Python programming language.

The dataset recording block consists of a dataset acquisition program which receives some parameters such as camera de-

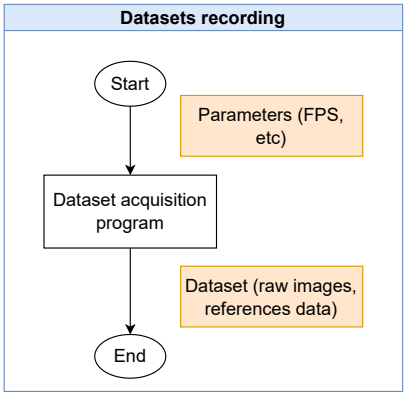

Fig. 2. Dataset recording data flow.

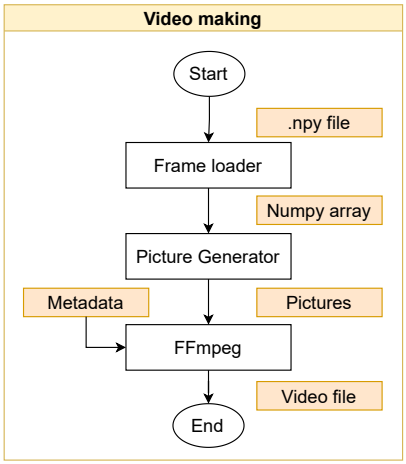

Fig. 3. Video-making data flow.

vice number, pulse oximeter address, frame rate, and duration of the dataset. After starting the program and inputting all the parameters, the program will start recording subject faces and save them as raw images contained in the NumPy array into a NumPy file format (NPY). This program also will save the reference data from the pulse oximeter in the same format. The process can be seen in Fig. 2.

The video making block consists of a frame loader and a video writing process. The frame loader unpacks the NumPy raw image file into a NumPy array which are then converted to PNG images with zero compression. After that, these images will be written into a video by using FFmpeg. The video encoder type used will be entered in this process. The process can be seen in Fig. 3.

The last block is performance benchmarking. Each video file is evaluated using an rPPG algorithm from our previous work [13]. This process produces an output in form of an

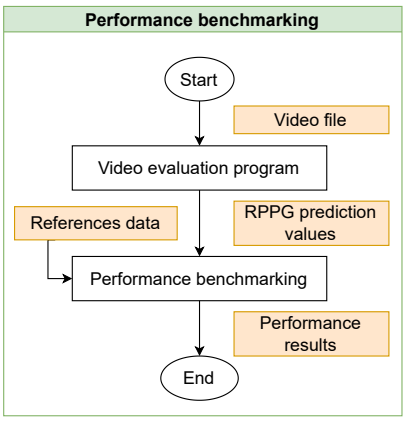

Fig. 4. Performance benchmarking data flow.

array of HR prediction values, which will proceed to the performance benchmarking sub-block. In this sub-block, mean absolute error (MAE) and root mean squared error (RMSE) will be calculated as performance metrics using the prediction and reference data array. . The process is shown in Fig. 4.

B. Video Encoding

Video encoding is a technique that allows video to be stored in much smaller size through compression because there is a lossy process involved. The process sweeps away some visual data in a video that is not really important so the visual data can be squeezed into fewer data bits. The video encoding process itself is determined by the video codecs or video compression standards.

*1) **Video Codecs**:* Video codecs are video compression standards carried out through software or hardware applications. They comprises two parts: an encoder and a decoder. The encoder is used to compress the video and the decoder is used to decode the encoded file and recreate the approximate original video. There are some publicly known video codecs such as x264, x265, FFV1 and etc.

Video codecs can be categorized into 2 categories: lossy and lossless. The key difference between these codecs is that lossless codecs try to preserve the video as it is while lossy codecs remove some part of the original data. Several popular lossless codecs used in this experiment are FFV1, HuffYUV, v410, and v210, whereas the used lossy codecs are x264, x265 (HEVC), VP9, and MPEG-4.

*2) **Video Containers**:* In this experiment, we also use some containers that comply with each codec used. Not to confuse with video codec, a video container is used to encapsulate everything such as encoded video and audio in one file. The different role between codec and container can be illustrated in Fig. 5. Some common containers were tested and used to provide complementary information in the final result.

*3) **Constant Rate Factor (CRF)**:* Constant Rate Factor (CRF) is one of the general rate control modes available in FFmpeg for x264, x265, and livbpx (VP9) encoder. By using this rate control, how many bits used in each frame

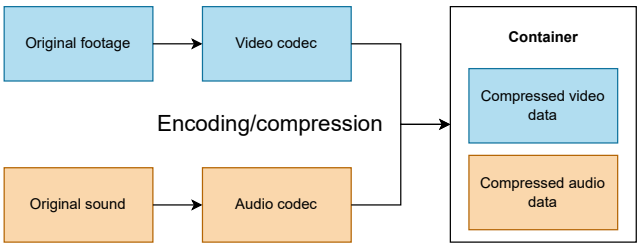

Fig. 5. Overview on video encoding process.

can be determined. By adjusting the so-called quantizer for each frame, it obtains the bitrate needed to keep the requested quality level [14]. In this experiment, the CRF range was 0 to 50 with an increment of 10.

4) ***Resolution****:* Resolution is considered an important factor to reduce the video file size. Each video was down-scaled using the FFmpeg scaler [10]. We tested different available resolutions and scaling algorithms.

C. Experimental Setup

The experimental setup consisted of a laptop equipped with a Logitech C920 camera [15] and connected to a pulse oximeter [16] to retrieve the ground truth (reference) data.

Data were recorded from 17 healthy subjects (9 males and 10 females) between the ages of 19 and 29. Each subject was sitting in a chair while facing his/her face to the camera that was 50 cm apart. Each recording was recorded for 90 seconds. All subjects gave their informed consent in accordance with the principles outlined in the Declaration of Helsinki. The ethical clearance was obtained from the Research Ethics Committee of the Bandung Institute of Technology, Indonesia (No. KEP/II/2022/X/M130723NA/PSPT).

For the downscaled video resolution data, the data from the highest resolution from each aspect ratio was downscaled to other lower resolutions. Downscaling was performed using several scaling algorithms provided by FFmpeg including fast bilinear, bilinear, bicubic, neighbor, area, gauss, lanczos, and sinc.

D. HR Estimation Algorithm

HR estimation algorithm used in this study was based on the rPPG algorithm described in [13] with modification to produce an HR estimate every 1 second. In [13], HR was estimated using all frames at the end, but in this new pipeline, the data was stored in a buffer until it was full, by which HR could then be estimated. After that, the new frames from the next 1 second were pushed into the buffer and the oldest 1 second frames in the buffer were popped out. By doing so, an HR estimate could be produced every second.

E. Performance Metrics

The performance for each video codec was measured using MAE and RMSE metrics. Performance results were displayed as a box plot, a bar plot, or a line plot. In the box plot, the horizontal line and the circle mark inside represent the median and mean, respectively. The colored solid box refers to the interquartile range (IQR) with the whisker extending to 1.5 times the IQR.

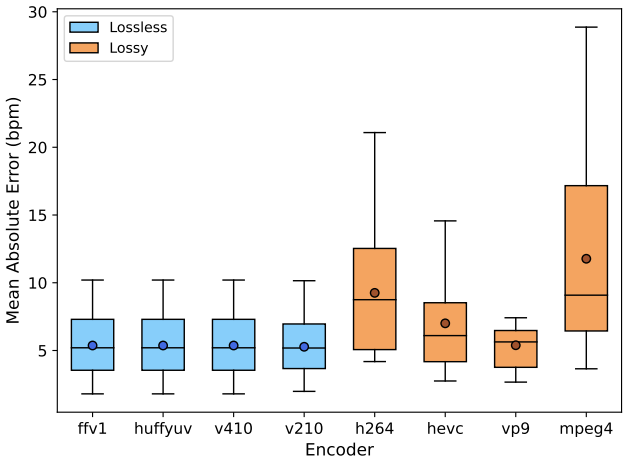

Fig. 6. Comparison between each encoder based on MAE metrics.

III. Results and Discussion

A. Lossless vs. Lossy Compression

In this experiment, for lossy compression, we used H264 or x264, H265 (HEVC) or x265, MPEG-4, and VP9. Whereas, for lossless compression, we used FFV1, HuffYUV, v410, and v210. All of these codecs are available in FFMPEG. The experimental results can be seen in Fig. 6.

According to the results, we can see that the lossless compression yields lower MAE than the lossy counterparts. FFV1, HuffYUV, v410, and v210 have better performance compared to the lossy compression encoders. This is due to the nature of lossless compression, which preserves the original bit data from the image. On the other hand, the lossy compression encoders have higher MAE because the output data is not the same as the original data. It can be caused by some factors such as inter-frame predictions, type of chroma sub-sampling, removed redundant frames, and motion compression.

Another important aspect is the reduction of file size. Lossy and lossless compressions have a big difference in the file size reduction. For this comparison, we take a sample to calculate the reduction in file size for each compression. Each file size is measured in a byte unit. The video resolution is 800 x 600 pixels. The comparison result can be seen in Fig. 7. Lossy compression can significantly reduce the file size to $0.1 - 0.3\%$ compared to the original file size. This reduction comes up with a trade-off, which is the decrease in the quality of image data due to the heavy compression algorithm used for producing output video. This trade-off heavily affects the quality of data for the rPPG algorithm which makes lossy compression having larger error as seen in Fig. 6. In this comparison, video codecs like H264, HEVC, and VP9 used the default CRF value.

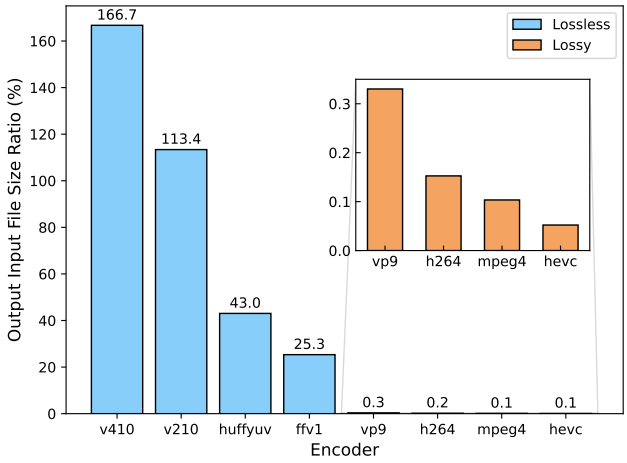

Fig. 7. File size reduction from the raw images.

On the other hand, the file size reduction using lossless was not as good as the lossy counterparts. It is due to the compression process in lossless compression is not as heavy as in lossy compression. It makes the output video file size still relatively large. We can also see that v410 and v210 resulted in larger file sizes than the raw file size. Therefore, v410 and v210 video codecs are not preferable for video compression. FFV1 produces the best result among the lossless by reducing the file size up to 25.30% and still keeps the performance metric similar to the other lossless compressions.

For the lossy compressions, the VP9 yields a relatively good file size reduction. It can compete with the lossless compressions while maintains lower variation on MAE over all subjects. The file size also could be compressed down to 0.3% size of the original file. It has been shown that lossy compression could be potentially used for video compression.

B. Effect on Different Container

As can be seen in the Table I, container does not affect the video quality. Different container is used for both lossless and lossy compression but none of them have differences. The data used for this experiment are just the top 3 subjects with lowest MAE over all codecs which causes the values slightly different from those shown in Subsection III-A.

Although there is no difference on the performance metrics on each video, different container has slightly different details. Using MediaInfo as video details checker, it is shown that .mkv has the smallest bitrate number among all these containers. For convenience, .avi can be selected to contain the video because it can be used to contain all types of encoder mentioned in this paper.

C. Effect of Constant Rate Factor (CRF)

Fig. 8(a) shows that the MAE tend to increase when the CRF value is increased. The default value for each encoder is different. For x264, 23 is the default value and for x265 (HEVC), 28 is the default CRF. Meanwhile, the default value for VP9 is 31. Near these default values, x265 and VP9 give

TABLE I
EFFECT OF DIFFERENT CONTAINERS

Encoder	Container	MAE	RMSE
FFV1	avi	2.32	2.97
	mkv	2.32	2.97
HuffYUV	avi	2.32	2.97
	mkv	2.32	2.97
v410	avi	2.32	2.97
	mkv	2.32	2.97
	mov	2.32	2.97
v210	avi	2.83	3.34
	mkv	2.83	3.34
	mov	2.83	3.34
H264	avi	5.02	6.26
	mkv	5.02	6.26
	mp4	5.02	6.26
HEVC	mkv	3.77	4.53
	mp4	3.77	4.53
MPEG4	avi	5.10	6.34
	mkv	5.10	6.34
	mp4	5.10	6.34
VP9	avi	4.60	5.54
	mkv	4.60	5.54
	mp4	4.60	5.54

better performance than x264. Overall, VP9 provides better performance than the other two encoders. It is also important to note that lowering CRF value will give higher bitrate and better quality, resulting in a lower MAE but at the same time will increase the file size, as shown in Fig. 8(b).

D. Effect of Resolution and Scaling Algorithm

Resolution tests were taken by using some common resolutions on 4:3 aspect ratio such as 640×480, 400×300, 320×240, 256×192, and 160×120. All of these resolutions were downscaled from the original video resolution of 800×600. In Fig. 9(a), it can be seen that increasing the resolution tends to reduce the MAE of HR estimation. This is because by increasing the resolution, the number of pixels contained by a video is also increased. Increasing the number of pixels means that the amount of information or the quality of the video also increases, leading to a decrease in the MAE of HR estimation. However, this comes at the expense of the increase in the file size as shown in Fig. 9(b).

IV. CONCLUSION

We have presented a comprehensive comparative evaluation of video codecs along with other relevant parameters such as video containers, quality rate mode, and resolution for rPPG based heart rate (HR) estimation. VP9 video codec provides balanced trade-off between the video quality, HR estimation accuracy, and file size. Even though video container does not affect HR estimation accuracy, .avi is preferable video container because it can contain all kinds of video encoders used in this study except x265 (HEVC). The decrease in the video resolution tends to increase the error in the HR

estimation, and vice versa. As a summary, this study could be useful for the creation of rPPG dataset and development of rPPG algorithm.

***Abstract*—Radar-based human activity recognition (HAR) is a fascinating research topic as it can be applied in various fields such as healthcare, security, and smart homes. As a non-invasive or non-contact technology that uses electromagnetic waves to detect human activities, radar offers the advantage of protecting visual privacy and remaining resilient against environmental conditions. Common machine learning (ML) methods used for HAR, such as Support Vector Machine (SVM) and k-Nearest Neighbor (KNN), depend on complicated parameter tuning, and high-dimensional data can degrade their efficacy. We propose a unified approach based on a convolutional neural network (CNN), specifically the VGG19 architecture with transfer learning, to extract features and classify various human activities from radar data. The advantage of using CNN is the ability to integrate feature extraction and classification in one learning phase. Transfer learning accelerates learning by utilizing pre-trained models' knowledge, enabling swift adaptation to new problem domains in machine learning. We compare our proposed method against traditional ML classification methods (SVM, KNN) and the combination of CNN-based feature extraction and ML-based classification methods. Our experimental results show that our proposed method performs better than the others with an F1-score of 93%.**

I. Introduction

Human activity recognition (HAR) can be defined as the ability to recognize/detect current activity based on information received from various sensors. HAR aims to understand human activity in daily life and apply it to various fields such as health, sports, security, transportation, etc. Falling is critical to detect because it can cause severe injury and even death, especially in the elderly and people with weakened health conditions [1]. Injuries caused by falling can also affect a person's quality of life and require significant medical expenses [2]. It makes falling a significant global public health issue.

Methods for conducting HAR can be categorized into three types: based on wearable sensors [3], [4], based on cameras [5], [6], and based on radar [7]–[10]. HAR uses wearable sensors such as accelerometers, gyroscopes, and magnetometers to record human movements on the wrist, waist, or ankles. It has relatively high accuracy, but it can cause discomfort to the user. The primary constraint of wearable sensor-based HAR is that monitoring the user's activities becomes unattainable if they forget to wear the device. Another method is using a camera for HAR. It provides richer visual information than the sensor data generated by wearable devices, but it is susceptible to environmental conditions and can raise privacy concerns for the user. Radar-based HAR is a non-invasive or non-contact technology that utilizes electromagnetic waves to detect human movements, which can protect visual privacy. Additionally, radar is a simple device and is not affected by environmental conditions.

The principle of radar-based HAR involves the detection of Doppler frequency shifts caused by human movement. Doppler frequency shift occurs when there is a change in frequency or wavelength of the electromagnetic wave due to the relative motion of the target [11]. This frequency shift gives rise to the sidebands, which are additional frequency components that appear around the original transmitted frequency of the target. These sidebands further generate micro-Doppler (μD) signatures that can be used to determine dynamic features of the target [12]. In HAR, the identified target is human activity involving motion patterns of various body parts. The micro-Doppler (μD) signature can uniquely represent human actions, thus providing data that can be classified [13].

The common approach to HAR is an image-based method. The main concept involves converting the radar signal into a matrix or feature map to streamline further processing. From this feature map, the relevant information is extracted. This extraction stage usually includes two types of methods: traditional methods and deep learning methods. Traditional methods generally apply machine learning (ML) [14] such as the use of Support Vector Machined (SVM) and k-Nearest Neighbors (KNN). Deep learning (DL) methods in HAR are attracting attention due to their superiority in automated deep feature extraction and big data processing [8], [10], [11], [13]. The first application of a convolutional neural network (CNN) to interpret a time-Doppler map as a 2-D image was carried out by Kim and Moon [8].

ML algorithms like SVM and KNN have strengths but also limitations. SVM excels at complex data classification yet can be computationally intense and struggle with skewed data. KNN relies on local data distribution and is sensitive to outliers, losing efficiency as data grows. Both require careful tuning, and high-dimensional data can challenge their

This research was funded by the Indonesia Endowment Fund for Education (LPDP) graduate scholarship program (grant number KET-3118/LPDP.4/2021).

979-8-3503-0067-3/23/$31.00 ©2023 IEEE

effectiveness. Thus, considering constraints and alternatives is essential when dealing with diverse and demanding datasets. We propose a unified approach based on a convolutional neural network (CNN), especially VGG19 architecture with transfer learning to extract features and classify various human activities on radar data. We compare our proposed method against traditional ML methods (SVM, KNN) and the combination of CNN and ML methods. As one of the most successful deep learning algorithms, CNN is able to integrate feature extraction and classification in one learning phase, utilizing hierarchical convolutional layers to discern crucial visual features automatically. As a result, CNNs can extract specific local features for HAR that may differ based on the type of human activity being observed. The use of transfer learning (TL) also offers a notable advantage by accelerating the learning process through the utilization of the pre-trained model's acquired knowledge. This approach accelerates initial training stages using existing features, enabling faster model convergence and reducing the demand for extensive labeled data. This efficiency conserves resources and time and facilitates rapid adaptation of expertise to new problem domains, enhancing the development of efficient machine learning solutions.

The paper is organized as follows: In Section II, the methodology for radar-based HAR is explained, starting from data collection to the classification of human activities. Section III presents the findings of the experiments and engages in a discussion about them. Section IV, the final section, presents the conclusion.

II. Methods

A. Radar Data Collection

This study obtained data from a public repository provided by the University of Glasgow [14]. The data was collected using a Frequency Modulated Continuous Wave (FMCW) radar at the operating frequency of 5.8 GHz, a bandwidth of 400 MHz, and a 1ms chirp duration. There were six recorded activities: walking, sitting down, standing up, picking up an object, drinking water, and falling. The dataset consists of 1754 data as a vector of 1280000 complex values. The distribution data for each class activity is shown in Table I.

TABLE I: The dataset class distributions

Activity	Label	Number of data
Walking	L1	312
Sitting down	L2	312
Standing up	L3	311
Picking up an object	L4	311
Drinking water	L5	311
Falling	L6	197
Total		1754

During the radar data collection, the FMCW radar had two transmitting channels and four receiving channel antennas [15]. The radar transmitted a signal through the transmitting antenna, and then the signal reflected by an object was received by the receiving antennas. The mixer merged the pulse frequencies from the transmitter and receiver to generate the intermediate frequency (IF) signal. Subsequently, the analog-to-digital converter (ADC) in the radar equipment transformed the IF signal into a digital format for additional processing. Digital signal processing (DSP) was used to obtain the beat signal, the raw radar data matrix [16].

When an object moves towards or away from a radar system, it can cause a change in frequency in the backscattered signal due to the Doppler effect. This effect can occur when using a monostatic radar system that sends out a sinusoidal signal, as described in [17]:

$$S_T(t) = A_T \sin(2\pi f_c t) \tag{1}$$

where A_T is the amplitude of signal Tx and f_c represents the carrier frequency.

The radar signal captured from the moving target can be represented as:

$$S_R(t) = 2\rho \sin(2\pi f_c t - 2\pi f_c \tau(t)) = 2\rho \sin(2\pi f_c t + \phi(t)) \tag{2}$$

where ρ is the path loss, $\tau(t)$ is the delay due to the target's motion, and $\phi(t)$ denotes the phase due to the Doppler effect. This signal is both shifted in frequency and reduced in amplitude compared to the originally transmitted signal.

Once the signal is received, it is demodulated and converted to a baseband signal:

$$S(t) = \rho e^{-j2\pi f_c \tau(t)} = \rho e^{-\phi(t)} \tag{3}$$

The Doppler shift can be defined by the phase difference between the transmitted and received radar signals, as described in [17]:

$$f_D(t) = \frac{1}{2\pi}\frac{d\phi(t)}{dt} = -f_c \frac{d\tau(t)}{dt} \tag{4}$$

B. Radar Data Processing

The radar-based HAR process algorithm is shown in Fig 1 and is implemented in Python. First, the raw data was processed into time-Doppler plots and spectrograms. The spectrogram was extracted to construct a matrix that was used as input for the machine learning (ML) classification method.

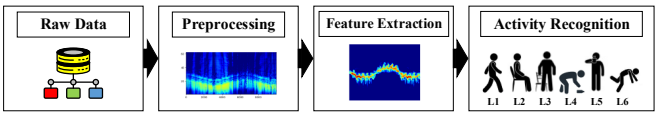

Fig. 1: The algorithm for radar-based HAR

The raw data was initially a 1D complex array and was processed through several steps. First, a fast Fourier transform (FFT) was performed on raw data to obtain the range profile in the time-range domain. Another FFT was then performed on the range profile to obtain the range-Doppler domain. Finally, a short-time Fourier transform (STFT) was performed on the range-Doppler domain to obtain the time-Doppler domain [15]. The time-Doppler domain provides information about the velocity and motion of various body parts of the target over time. When a person is in motion, the radar registers the radial

velocity of the object, and the change in the frequency of the reflected signal is referred to as the Doppler shift. This Doppler shift data contains speed details for distinct body parts, which vary as a person engages in different activities. Consequently, scrutinizing the Doppler shift enables the identification of the ongoing activity.

In the case of the 5.8 GHz FMCW radar, the wavelength can be calculated as $\lambda = \frac{c}{f} = 5.2\,\text{cm}$. Although the Doppler shift will not produce a perceivable change in frequency, there will be a considerable change in phase. The change in phase can be acquired by:

$$\Delta\phi = 2\pi f_c \Delta\tau = \frac{4\pi\Delta d}{\lambda} \tag{5}$$

As an illustration, when the scan period (T_c) is 1 ms and the velocity of the target is 10 m/s, the phase shift between each chirp will be approximately $13.8°$, whereas the range displacement during one chirp will only be 0.01 m. This indicates that the variation in phase between the peaks of two successive chirps holds the data on the target's velocity. If we substitute the relative displacement of the target as $\Delta d = vT_c$, we can obtain the velocity using the following formula:

$$\Delta\phi = \frac{4\pi v T_c}{\lambda} => v = \frac{\lambda\Delta\phi}{4\pi T_c} \tag{6}$$

C. Activity Recognition

This section involves the process of mapping the spectrum domain data obtained from radar signal processing to the features used for HAR.

1) K-Nearest Neighbors (KNN): The KNN is a simple and easy-to-implement classification algorithm, which assumes that data with the same label are normally near to each other. To classify a new data point or query, KNN calculates the distance between the query and all the training points in the dataset. The distance is usually the Euclidean distance, but other distance metrics can be used as well. Once the distances are calculated, the KNN algorithm sorts them and selects the k training points that are closest to the query [18]. The KNN algorithm was implemented using the Scikit-learn library in Python, with a specified value of $k = 5$.

2) Support Vector Machine (SVM): SVM is essentially a non-probabilistic binary linear classifier, meaning that an SVM training algorithm builds a model that assigns new examples to one category or the other [19]. SVM is a binary classification algorithm. In this case, a multiclass SVM algorithm was employed for classification using the "one vs all" strategy. This strategy involves training N different binary classifiers. Each classifier undergoes training to differentiate samples within a specific class from all other classes. When a new sample is encountered, all N classifiers are executed, and the classifier that produces the highest output is selected [20].

3) Convolutional Neural Network (CNN): CNN is a deep learning algorithm specifically designed for processing and analyzing visual data. CNN will automatically learn the hierarchical representation of visual data using multiple layers of interconnected neurons. A CNN typically comprises three primary building blocks: convolution, pooling, and fully connected layers. These layers are organized in a layered structure to extract higher-level information for classification purposes effectively [17]. Fig 2 illustrates how a simple CNN model can be visualized.

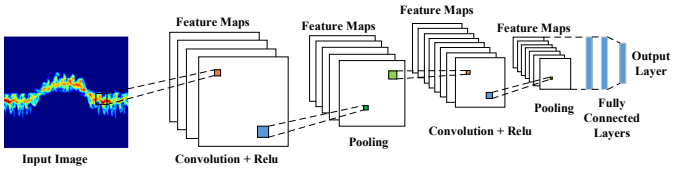

Fig. 2: An example of CNN architecture

In this study, CNN was used for pattern recognition based on micro-Doppler (μD) data that was translated into spectrogram data. The existing CNN were used such as ResNet50 [21], MobileNetV2 [22], VGG16 [23], and VGG19 [23]. To get the data into the right input format, the data was transformed to the time doppler-velocity spectrogram and rescaled to the desired 224x224 pixels.

III. Results and Discussion

This section presents and discusses our experimental results on the entire dataset. The dataset was divided randomly into three portions: 80% for training, 10% for validation, and 10% for testing. The dataset division utilized stratify feature to ensure that the proportions of each class remain balanced between the training and testing sets. We computed the weighted mean of classification accuracy, F1-score, and confusion matrix for every experiment.

A. Radar Data Processing

The dataset contains a raw data vector consisting of 1280000 complex values. This vector was converted into chirps, resulting in a 128×10000 complex-valued matrix. The matrix was then subjected to FFT to obtain range-time data. A moving target indication (MTI) filter removed unwanted signals. The filtered range-time data was then used to generate spectrograms. Fig 3 shows the spectrogram outcomes of each activity, indicating differences among all the activities.

B. Activity Recognition

In this study, we recognize human activity from radar data using the VGG19 architecture with transfer learning approach. The result of this method will be compared to traditional ML methods (SVM, KNN) and the combination of CNN and ML methods. In the early stages, a simple technique was used, which involved manual resizing and flattening of the spectrogram images to serve as input for the KNN and SVM classifiers. In addition, activity recognition using CNN through transfer learning (TL) was carried out early with different configurations such as ResNet50, MobileNetV2, VGG19, and VGG16. The feature representations were flattened and sequentially propagated through four dense layers. The final output was obtained using a softmax activation layer. In the

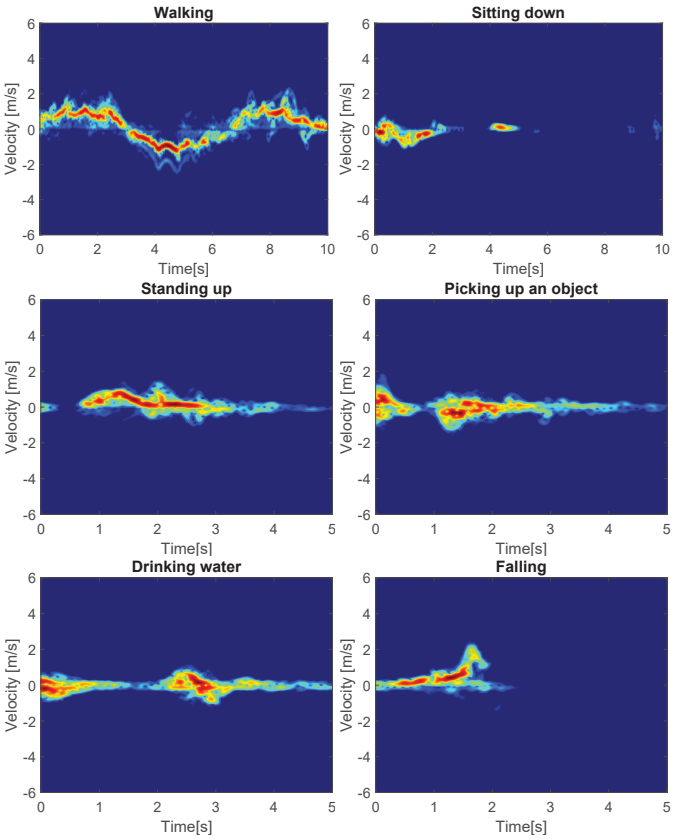

Fig. 3: Spectrogram of six human activities

final phase, activity recognition was performed using CNN as the feature extraction method and KNN and SVM as the classifiers. Fig 4 visualizes the activity recognition. The evaluation results for the different methods are presented in Table II, which shows the performance of each approach.

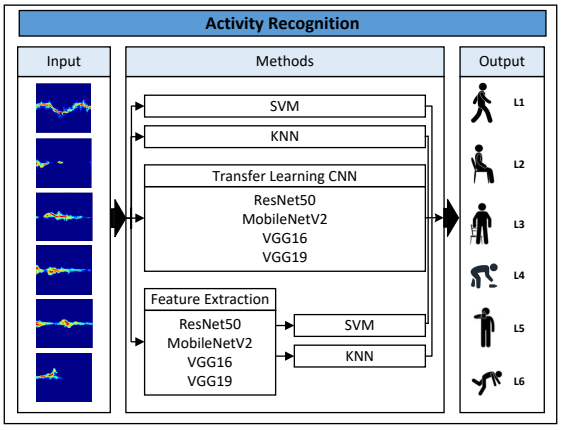

Fig. 4: Visualization of radar-based HAR

In the initial stage, the simple KNN configuration shows that the classification speed decreases with the increasing number of datasets used. The accuracy obtained with the parameter $k = 5$ is 89%. To estimate the accuracy of the KNN

TABLE II: Evaluation on different methods

Feature Extraction	Methods	Train Acc(%)	Test Acc(%)	F1 Score(%)
-	SVM	92	89	89
-	KNN	90	90	89
ResNet50-TL		80	86	86
MobileNetV2-TL		88	89	89
VGG16-TL		88	90	90
VGG19-TL		**90**	**93**	**93**
ResNet50	SVM	89	89	89
MobileNetV2	SVM	90	93	93
VGG16	SVM	91	92	92
VGG19	**SVM**	**90**	**92**	**93**
ResNet50	KNN	83	84	84
MobileNetV2	KNN	79	80	81
VGG16	KNN	88	85	85
VGG19	KNN	86	86	86

algorithm for the different configurations of features applied, the K-fold cross-validation approach was applied. The simple SVM configuration also provides the same accuracy value of 89%. Furthermore, activity recognition is carried out using deep learning called CNN with several configurations. The configurations used are ResNet50, MobileNetV2, VGG16, and VGG19. To train the CNN, the optimizer used was Adam, with a learning rate of 0.001. Sparse Categorical Cross Entropy was selected as the loss function since only one value at the output represents a classification label. The network was trained for 30 epochs with early stopping. At the end layer of the pre-trained model, we customize it by adding several dense layers. The accuracy results obtained sequentially were 86%, 89%, 90%, and 93%. Good results were obtained from the utilized configuration. The acquisition of activity recognition accuracy with KNN, SVM, and CNN shows that CNN is better at activity recognition. The confusion matrix in Fig 5 shows the best configuration performance of the CNN algorithm with VGG19 architecture.

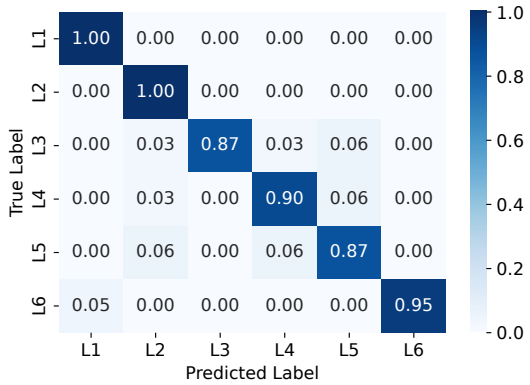

Fig. 5: Confusion Matrix VGG19-TL

Feature extraction uses CNN to speed up the model classification training time and get better results. Furthermore, the feature extraction results are input to the KNN and SVM

classifiers. Various configurations were used to evaluate the accuracy of the KNN algorithm, and the best accuracy of 86% was achieved by using VGG19 as feature extraction. In this case, the value of $k = 5$ is used to achieve optimal results. As previously stated, SVM is a binary classifier. However, HAR requires multiclass classification, so the "one versus all" strategy is used. Various configurations are used to assess the accuracy of the SVM algorithm. The confusion matrix in Fig. 6 shows the performance of the VGG19-SVM algorithm. Compared to the previous case, SVM gives superior results to KNN. Based on Table II, the comparison results of various methods indicate that both the VGG19-SVM and VGG19-TL models yield similar performance, with the highest accuracy of up to 93%. However, VGG19-TL holds an advantage, wherein feature extraction and classification are executed within a unified approach rather than separately. Another benefit of VGG19-TL is its potential for optimization to run on embedded devices or hardware accelerators through techniques like pruning and quantization. However, classifiers for L4 and L5 have the lowest accuracy.

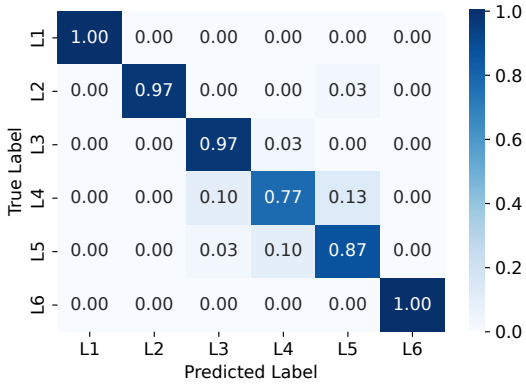

Fig. 6: Confusion Matrix VGG19-SVM

Additionally, a comparison is conducted between the proposed method and the reference method. The comparison reveals that the CNN (VGG19-TL) and the CNN-SVM methods with MobileNetV2 and VGG19 feature extraction exhibit superior accuracy compared to the other methods and study by Shah et al [14]. Shah et al. proposed GoogleNet, AlexNet+KNN, and AlexNet+SVM with performances of 75%, 77%, and 78%, respectively.

C. Future Works

Generally, radar-based HAR is implemented on the cloud or desktop. The future works will address the implementation of radar-based HAR on embedded systems because it offers several benefits, such as portability, data privacy, and low power consumption. The challenges for its implementation include real-time data processing, adaptation to changing environments, and using technology capable of processing radar-generated data. Therefore, the development of radar-based HAR on embedded systems still requires further research.

IV. Conclusion

This paper proposes radar-based human activity recognition (HAR) algorithm with a unified approach based on a convolutional neural network (CNN), especially VGG19 architecture with transfer learning. It presents its performance benchmark against other methods on a public dataset of people performing six daily activities. We compare our proposed method against traditional ML methods (SVM, KNN) and the combination of CNN and ML methods. The basic configuration for KNN and SVM achieves only about 89% accuracy. The CNN method achieves higher accuracy than KNN and SVM of 93%. Feature extraction is also needed to speed up the classification model training time and get better results. The KNN approach has the highest accuracy of 86%, with VGG19 as feature extraction. Furthermore, the SVM model using the "one vs. all" strategy was implemented for multi-class classification, achieving an accuracy of about 93% with MobileNetV2 and VGG19 as feature extraction. The VGG19-TL model produces the best accuracy of all the models performed. The VGG19-TL offers the advantage of unified feature extraction and classification alongside the potential for optimization to operate efficiently on embedded devices or hardware accelerators via techniques such as pruning and quantization.

***Abstract*—Reinforcement Learning is an algorithm with decision-making based on the Markov Decision Process (MDP). MDP uses actions that are assessed by rewards to achieve the goal depending on the environment. An action is taken by a policy. In this work, we consider a maze-based shortest path problem. The maze problem is solved based on the value of Q from the chosen action. The ordinary Q-learning algorithm uses these value-based states in two modes; explore and exploit. However, the continuous states require initialization. The problem appears in very large states. Thus, in this work, deep learning in the form of neural-network is embedded to determine the Q-value called by Deep Q-Network (DQN). The neural network architecture has a different number of layers and neurons for each implementation. Moreover, the implementation of agents on edges has limited resources. Thus, it requires an optimal architecture to achieve the goal. This study uses an environment maze with a size of 20×20 with four actions; up, down, left, and right to reach the destination state or goal. In this paper, we study how to get the optimum processing elements (PE) to be implemented in limited resources of edge computing. Experimental results show that the minimum number of layers of three layers with 14 hidden neurons, and 200 deep replay memory from DQN architecture have been able to complete the shortest path on a maze with a size of 20×20. The finding effectively minimizes the amount of computing and potential for edge computing applications.**

I. Introduction

Reinforcement Learning Algorithm is a sequential-based machine learning using the Markov Decision Process (MDP) to solve the problem without prior knowledge [1]. The algorithm requires a large computing resource to do exploration and exploitation while calculating the Q-Value (Quality). The Q-value will determine the action of the agent toward the goal. This becomes an issue when it is implemented with limited resources in edge computing [2].

The process starts by an agent takes action in the environment then the environment produces a state. Then, the state will be fed to a reward function, and the result is the reward (of the action). Moreover, based on the reward, the agent will take the next action to the environment. The agent needs to determine the best action using a reinforcement learning algorithm, which has value base and policy base algorithms. The best action is the one that gains the highest rewards.

The Deep Q-Network (DQN) algorithm implementations for finding optimal paths in robot navigation is resulted a better performances than A* and Dijkstra algorithms [3]. An application of DQN to finding the best path, utilizing guidance from A*, has been employed in an Automated Guided Vehicle (AGV) system for a Robotic Mobile Fulfillment System (RMFS). This application resulted a 71.51 % reduction in decision-making time for the complex model design of RMFS [4]. Thus, the DQN algorithm provides a promising solution for determining the best path in robot navigation. Edge computing has limited resources. In this specific case, the edge is designed to implement the Q-Leaning algorithm [2] despite the limitations it has. Thus, to increase the computational speed, the Reinforcement Learning (RL) algorithm is applied to an accelerator to provide a significant improvement in speed while reducing power consumption [5]. For instance, the implementation of deep Q-Learning in an Atari Game requires a relatively large amount of memory and a long period of consumption for training the network model. [6]. There are several approaches to expedite computational timing, including the utilization of Graphic Processing Units (GPUs), Tensor Processing Units (TPUs), and accelerators. [2]. The implementation of accelerators in this case has been proven to increase computational capacity while maintaining significantly lower power consumption compared to GPUs and TPUs. [7]–[11]. In order to ascertain the required calculation power for edge computing implementing DQN, it is imperative to initially outline the precise algorithm and artificial neural network (ANN) model. This process will involve minimizing the count of Processing Elements (PE) within the Computer System. The design will yield a more efficient model, considering the number of neurons and replay memory employed for problem-solving [12].

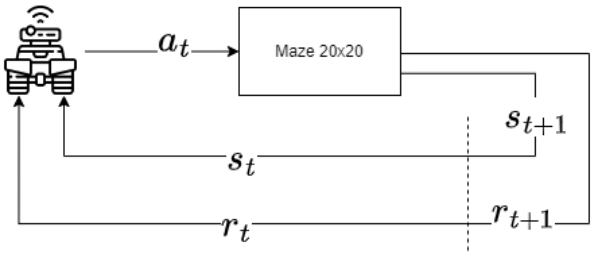

Fig. 1: Reinforcement Learning

The objective of this research is to identify the optimal

model by determining the appropriate number of neurons for the implementation of DQN in solving maze environments (Fig. 1). The experiments will investigate different options for the number of neurons, within 8, 10, 12, 14, 16, and 32, in order to achieve an optimal solution. Additionally, the study will encompass varying depths of replay memory options, specifically 50, 100, 150, and 200 for Deep Replay Memory (D). The outcomes of this study will play a crucial role in determining the required number of Processing Elements (PE) and on-chip memory necessary for the design of computing on Edge Computing.

II. DQN Algorithm

In this section, we explain our proposed method; the DQN for maze-based shortest path solver and the environment where the research is taking place.

A. Deep Q-Network Algorithm for Maze Solving

The algorithm developed in this study is the Deep Q-Network (DQN), which computes an Approximate Q-Value using a Neural Network (Alg. 1). This process is depicted in algorithm 1 based on [6], The replay memory is exclusively employed within each episode and is reset at the commencement of the subsequent episode. The algorithm is implemented for robot agents to ascertain the shortest paths in a 20 $\times$ 20 maze environment.

B. Environment of the Maze

The environment employed in this study features a maze with dimensions of 20 $\times$ 20, as illustrated in Figure 2. The neural network takes a state input of 400 neurons, and the objective of the agent is to navigate toward the destination state by identifying the shortest path. The maze used in a 20$\times$20 environment is of a complexity level suitable for maze solving. If a smaller maze is used, the computational time complexity decreases, and the memory requirements also decrease, and vice versa.

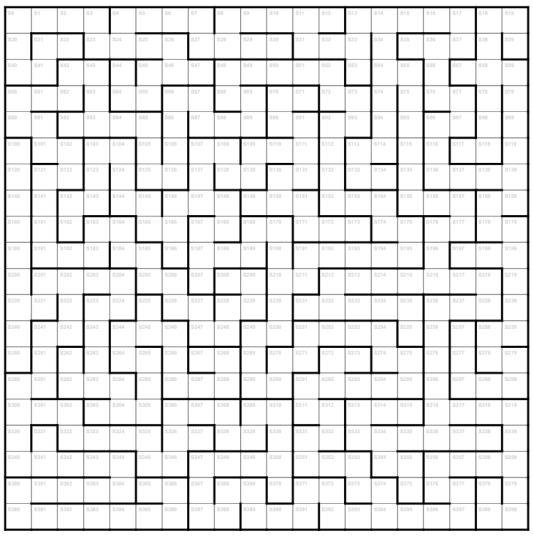

Fig. 2: Environment

III. Computational System Design for DQN Algorithm

A. Neural Network Design

The network design which is employed in the Deep Q-Network (DQN) utilizes a structure comprising three layers: the input layer, the hidden layer, and the output layer. The size of the weights for each of these layers is illustrated by Equation 1 and 2.

$$w^2_{i,j} = X_i \times Z2 \tag{1}$$

$$w^3_{i,j} = Z2 \times Z3 \tag{2}$$

The size of the bias value is determined based on the number of hidden layers and output layers. The quantities of weights and biases in the neural network model are presented in Table I.

In the computation of the Deep Q-Network (DQN), the input processing is based on Equation 3 utilizing one-hot encoding. The feed-forward equation is derived from Equation 4, it is involving a computational process of weight multiplication with neurons and the addition of input with the bias associated with each perception. The chosen activation function is the sigmoid

TABLE I: Size of Weight and Bias in DQN Neural Network

	Neuron					
Parameter	8	10	12	14	16	32
#Weight Layer 2	3,200	4,000	4,800	5,600	6,400	12,800
#Bias Layer 2	8	10	12	14	16	32
#Weight Layer 3	32	40	48	56	64	128
#Bias Layer 3	4	4	4	4	4	4
#Number of WB	3,244	4,054	4,864	5,674	6,484	12,964

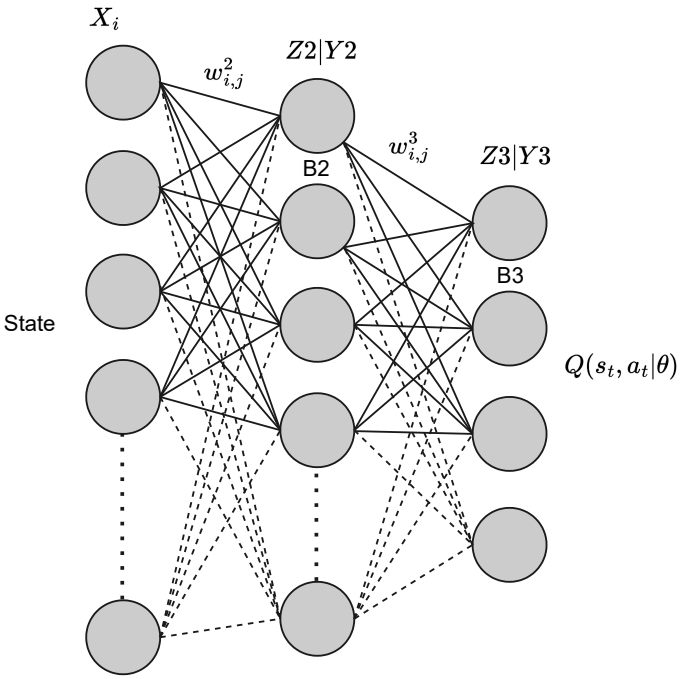

Fig. 3: Network Design for DQN

function, as depicted in Equation 5. The reward function is established according to Equation 6, where the agent receives a reward of 10 upon reaching the goal, -10 for being hit with a wall, and -1 for moving without encountering obstacles. The cumulative reward calculation is expressed in Equation 7. The algorithm's performance is assessed using the Success Rate parameter, which signifies the agent's achievement in reaching the goal within a specific time frame. In this experimental context, 1000 episodes are used, as shown in Equation 8.

$$a_j^1 = \begin{cases} 1, & \text{if } s_t = j \\ 0, & \text{otherwise} \end{cases} \tag{3}$$

$$y_j^m = f^m\left(\sum_{1=1}^{I_m}(w_{i,j}^m \times y_i^{m-1}) + b_j^m\right) \tag{4}$$

$$f(x) = \frac{1}{1+e^{-x}} \tag{5}$$

$$r_t = \begin{cases} 10, & \text{if Agent reaching the Goal} \\ -10, & \text{if Agent Hits the Wall} \\ -1, & \text{otherwise} \end{cases} \tag{6}$$

$$R = \sum_{t=1}^{E} \times r_t \tag{7}$$

$$S_r = \frac{E_{goal}}{E_p} \times 100\% \tag{8}$$

After the Neural Network calculates the feed-forward process, the Deep Q-Network computes the Q-Value State's reward using Equation 10 to obtain the target value. The calculation of the Loss Function, utilizing MSE (Mean Squared Error), is depicted in Equation 9.

$$L(\theta) = \frac{[r_t^{'} - Q(s_t, a_t : \theta)]^2}{2} \tag{9}$$

$$r_t^{'} = r_t + \gamma \times \max Q(s_{t+1}, a_{t+1}|\theta) \tag{10}$$

To ascertain the weight and bias updates, a back-propagation process is employed, utilizing a chain rule (Eq. 11) in line with the stochastic gradient descent (SGD) approach (Eq. 12 and Eq. 13), incorporating replay memory $[s_t, a_t, r_t, s_{t+1}]$.

$$\frac{\delta L}{\delta w_{i,j}^j} = \frac{\delta L}{\delta z_{i,j}^j} \times \frac{\delta z_{i,j}}{\delta w_{i,j}^j} \tag{11}$$

$$w_{i,j}^{'m} = w_{i,j}^m - \alpha \Delta w_{i,j}^m \tag{12}$$

$$b_i^{'m} = w_{i,j}^m - \alpha \Delta b_{i,j}^m \tag{13}$$

The computation for stochastic gradient descent (SGD) involves calculating of derivatives through back-propagation, leading to weight and bias updates for layer 3, as demonstrated in Equations 14 and 15.

$$\Delta w_{i,j}^3 = Y_i^3 - r_t^{'} \times Y_{i,j}^2 \tag{14}$$

$$\Delta b_i^3 = Y_i^3 - r_t^{'} \tag{15}$$

The weight and bias updates for layer 2 are presented in Equations 16 and 17.

$$\Delta w_{i,j}^2 = \Delta w_{i,j}^3 \times w_{i,j}^3 \times (1 - Y_{i,j}^2) \times Y_j^2 \tag{16}$$

$$\Delta b_i^2 = \Delta w_{i,j}^3 \times w_{i,j}^3 \times (1 - Y_{i,j}^2) \times Y_{i,j}^2 \tag{17}$$

Following Equations 12 and 13, the subsequent step involves the back-propagation process, utilizing Equations 18 and 19.

$$w_{i,j}^{'3} = w_{i,j}^3 - \alpha \times Y_{i,j}^3 - (r_t + \gamma \times maxQ(s_{t+1,a_{t+1}|\theta}) \times Y_i^2 \tag{18}$$

$$b_i^{'3} = b_i^3 - \alpha \times Y_{i,j}^3 - (r_t + \gamma \times maxQ(s_{t+1,a_{t+1}|\theta}) \tag{19}$$

Furthermore, to update the weights and biases in layer 2, we use Equations 12 and 13. These equations are substitutions derived from Equations 16 and 17, and they are demonstrated in Equations 20 and 21.

$$w_{i,j}^{'2} = w_{i,j}^2 - \alpha \times \Delta w_{i,j}^3 \times w_{i,j}^3 \times (1 - Y_{i,j}^2) \times Y_{i,j}^2 \tag{20}$$

$$b_i^{'2} = b_i^2 - \alpha \times \Delta w_{i,j}^3 \times w_{i,j}^3 \times (1 - Y_{i,j}^2) \times Y_{i,j}^2 \tag{21}$$

B. DQN Hyper-Parameter Design

DQN training necessitates the initialization of parameters to ascertain the values shown in Table II for achieving an effective number of neurons in the experiment. Additionally, Table III is utilized to determine the size of the replay memory, which stores the agent's experiences $[s_t, a_t, r_t, s_{t+1}]$ in the environment for training the algorithm.

TABLE II: DQN Hyper-Parameter With Variable Number of Hidden Neurons

Parameters	Value
Number of Layer	3
Number of State Units	**400**
Number of hidden units	**8, 10, 12, 14, 16, and 32**
Number of Output Layer units	**4**

C. Hardware for Training and Implmentation of DQN

This DQN algorithm model is executed on a computer equipped with an Intel Xeon Gold 5218 processor, featuring 16 cores operating at 2.294 GHz, and 128GB of RAM.

IV. Experiment Results

The training results are illustrated in Figure 4, depicting 50 paths from the initial state (s0) to the goal state (s399). Algorithm 1 successfully determines the shortest path for a 20x20 maze using the DQN approach.

Based on the experimental results, the success rate appears to converge around episode 250×10^3, as illustrated in Figure 6. The convergence of computation time requires approximately 1×10^4 to 2×10^4 seconds, as shown in Figure 7. The experimental findings reveal that a hidden neuron count of 14 is necessary to achieve a 100% convergence success rate, depicted in Figure 6.

When performing computational operations within the DQN algorithm, the determination of the number of Processing

#Overall PE	4,160,000	5,200,000	6,240,000	7,280,000	8,320,000	16,640,000

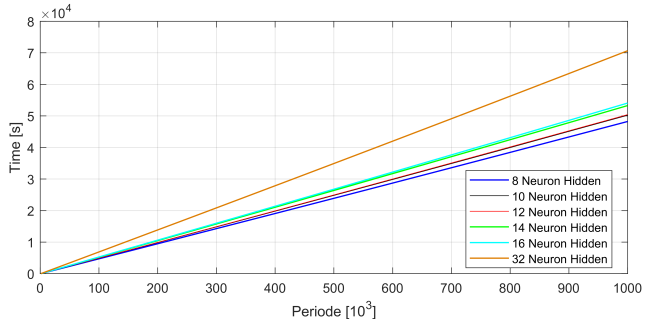

Fig. 7: Computation Time of DQN with neuron size in Hidden layer

Elements (PE) is also carried out during the feed-forward process. This calculation is based on equations 4 and 5, involving a count of the neurons without the Sigmoid activation function. In this context, **X** represents the input neurons, **Z2** denotes the hidden layer, and **Z3** corresponds to the output layer. The computation involving adders is employed in bias calculations for the hidden layer (**B2**) and the output layer (**B3**).

$$PE(MLP)_{mul} = (X \times Z2) + (Z2 \times Z3) \quad (22)$$

$$PE(MLP)_{add} = ((X-1)\times Z2)+((Z2-1)\times Z3)+B2+B3 \quad (23)$$

Based on the hyper-parameters in Table II, where each episode comprises 400 steps, the effective number of Processing Units (**PE**) required for 250×10^3 Episodes (**E**) and 400 steps per episode (**T**) determines the necessary computational resources. The computation of the activation function in Equation 5 involves employing the *numpy* exponential function [13], utilizing a computation process based on the exponential function [14] and employing a power series approach as outlined in Equation 24. This process requires n-1 adders, $2 \times (n-2)$ multipliers, and $N-2$ divisions. In addition to the Sigmoid Activation Function described in Equation 5, one extra division and one additional adder are necessary.

$$e^x = \sum_{n}^{\infty} \frac{x^n}{n!} = 1 + x + \frac{x^2}{2!} + \frac{x^3}{3!} + ..., \quad (24)$$

The computation involved in the backpropagation process is determined by equations 18, 19, 20, and 21. For updating W3, the number of Processing Elements (PE) requires is 2 subtractors, 1 adder, and 3 multipliers. For updating B3, the requirement is 2 subtractors, 1 adder, and 3 multipliers. Updating W2 and B2 requires 2 subtractors and 4 multipliers.

$$PE(sigmod)_{add} = (Z2 \times (N-1)) + 1 \quad (25)$$

$$PE(sigmod)_{mul} = (2 \times (N-2)) \times Z2 \quad (26)$$

$$PE(sigmod)_{div} = (Z2 \times (N-2)) + Z2 \quad (27)$$

The number of Processing Elements (PE) in the feed-forward process (Eq. 28) is the result of adding together the summation of weights and input neurons, along with all the bias in the Sigmoid function, within layer 2.

$$PE(FeedForward) = PE(MLP) + PE(sigmoid) \quad (28)$$

The number of Processing Elements (PE) used in the feed-forward process reached convergence by the episode indicated in Equation 29.

$$PE(FeedForward)_{conv} = PE(FeedForward) \times E \times T \quad (29)$$

The experimental results for various sizes of replay memory (50, 100, 150, and 200) in Deep Replay Memory are depicted in Figure 8 for cumulative reward and Figure 9 for success rate at each replay memory size.

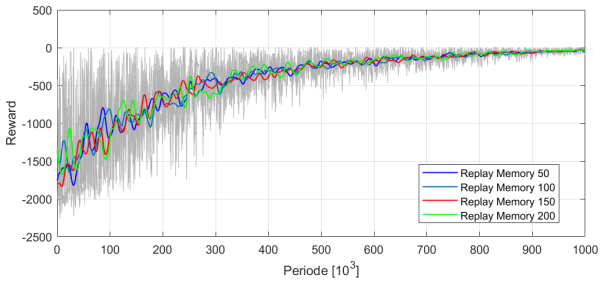

Fig. 8: Cumulative Reward of DQN with Different Replay Memory Sizes

For a replay memory size of 200, the details are provided in Table VI. Regarding the computation for 250×10^3 Episodes, the back-propagation computation time is illustrated in Equation 30, with the number of computations being $T-D$ per episode, where T represents the steps per episode and D signifies the depth of the replay memory.

$$PE(BP)_{convergen} = PE_{BP} \times (T-D) \times Episode \quad (30)$$

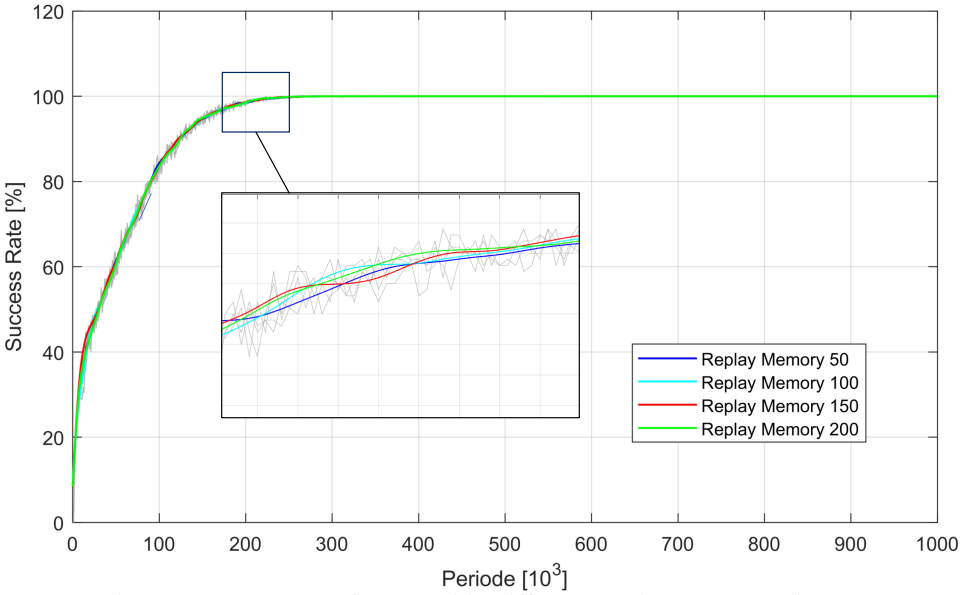

Fig. 9: Success Rate of DQN with Different Replay Memory Sizes

#Multiplier	3,882,000	4,851,600	5,821,200	6,790,800	7,760,400	15,517,200
#Overall PE	5,839,200	7,297,200	8,755,200	10,213,200	11,671,200	23,335,200

TABLE VI: Processing Elements Utilized by DQN for Back-propagation with 200 Replay Memory per Episode

	Neuron					
Parameter	8	10	12	14	16	32
#T per-episode	400	400	400	400	400	400
#Replay Memory	200	200	200	200	200	200
#Adder	7,200	8,800	10,400	12,000	13,600	26,400
#Subtractor	1,297,600	1,621,600	1,945,600	2,269,600	2,593,600	5,185,600
#Multiplier	2,588,000	3,234,400	3,880,800	4,527,200	5,173,600	10,344,800
#Overall PE	3,892,800	4,864,800	5,836,800	6,808,800	7,780,800	15,556,800

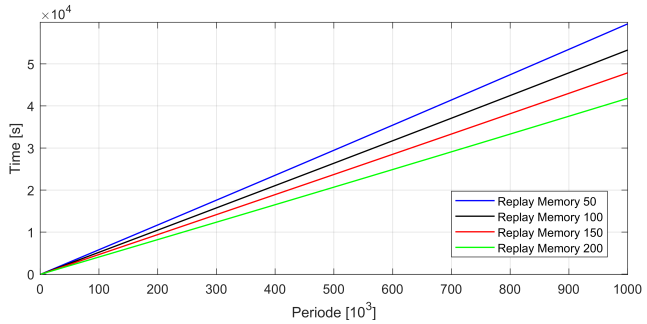

Fig. 10: Computation Time of DQN with Different Replay Memory Sizes

The computational requirement for a smaller replay memory is reduced because the back-propagation process is conducted over a shorter time period. However, the Success Rate and Reward Function exhibit nearly identical values across different replay memory sizes. Consequently, employing a replay memory with a depth of 200 proves to be more efficient by utilizing Processing Elements (PE) compared to utilizing a replay memory with a depth of 50. The edge device which will be use to solve the shortest path problem in a maze by a mobile robot will be implementing FPGA in the system. The number of processing elements (PEs) which are required on the edge device will affect the system's complexity, the goal is ensuring that the optimum value generated by the DQN

Algorithm model provides an efficient system comparable to full computing device. Based on the experimental results, an effective neuron count is determined to be 14 hidden layers with a replay memory depth of 200. Consequently, this necessitates a total of 7,280,000 PEs for feed-forward and 6,808,800 PEs for back-propagation per episode. For implementation on the edge device, parallelization and approximation techniques need to be employed to reduce resource usage on the FPGA that will be utilized.

V. Conclusion

The design of the DQN algorithm for determining the shortest paths in a maze of size 20x20 is adaptable to edge computing. The Neural Network model employs 14 neurons in the Hidden Layer and a Replay Memory of 200. The feed-forward process involves 2,396,800 adders, 4,597,600 multipliers, and 285,600 divisions as Processing Elements (PE). For back-propagation, using 14 neurons in the Hidden Layer and a Replay Memory depth of 200, the required PE amounts to 12,000 adders, 2,269,600 subtractors, and 4,527,200 multipliers. The algorithm attains convergence over 250×10^3 episodes, demanding a total of 3.522×10^{12} PE. In the context of accelerator DQN on edge computing, an approximation process and parallel computation are imperative for efficient execution.

***Abstract*—The renewable energy, especially photovoltaic (PV), is growing exponentially for being able to harvest solar power, which is abundant, especially in tropical countries, like Indonesia. There is the limit of the power harvested, first is PV efficiency and also how the generated power is transferred to the load. The power generated by PV (P_{PV}) should be able to be transferred to the load close to its maximum generated power. This task is done by an MPPT (Maximum Power Point Tracking) module in the PV System. MPPT has been widely implemented especially the conventional methods like Perturb and Observe (P&O). The review of conventional and even AI-based MPPT elucidates problems when MPPT transfers the power during the partial shading condition (PSC) and also at low generated power. The power fluctuates and is significantly inefficient in both conditions respectively. The latest studies showed that MPPT by Deep Reinforcement Learning (DRL) has provided a stable and more efficient P_{VP} compared to P&O and other conventional methods. The study in this research continues the previous one on DRL by reproducing MPPT using DQN (Deep Q-Network) and DDPG (Deep Deterministic Policy Gradient) and introducing TD3 (Twin Delayed Deep Deterministic Policy Gradient). The study shows that at irradiation 1000W/m^2 condition, TD3 produced output power 8.37% higher than DDPG and 1.61% higher than DQN. Then at low irradiation, 250W/m^2 TD3 is higher 13.93% than DDPG but lower 29.27% than DQN. On both conditions TD3 is the least fluctuated, the standard deviation is 0.02, while DQN is 4.04 at clear day and DDPG is 5.8 at cloudy day. This is a promising outcome for renewable energy harvesting, especially on a large scale.**

***Index Terms*—Photovoltaic, MPPT, Deep Reinforcement Learning, DQN, DDPG, TD3**

I. Introduction

Deep reinforcement learning has been applied to many applications including PV systems. The PV system required a controller to ensure the power generated by the PV module transferred to the load efficiently or as much as possible. [1] The PV system consists of PV, Converter, Controller of the Converter, and Load. MPPT is the controller, and it drives the converter to maximize the power transfer. MPPT works based on the information of PV specifications provided by the PV manufacturer. The specification has important information such as the maximum power PV could generate, maximum current and voltage (maximum power point), and the impact of temperature on the PV generated capacity. In uniform conditions, PV is expected to generate at its maximum capacity and less in non-uniform conditions. In uniform conditions, the temperature factor controls the maximum capacity of PV. On the contrary, in non-uniform conditions, the maximum capacity of PV is controlled not only by temperature factor but also by voltage level of PV, low irradiation will make PV cells provide less voltage than its rating. [2] Based on the conditions above, there is a requirement for MPPT to handle various conditions of PV systems as input and keep the maximum possible power output transferred to the load. This requirement has been handled by many conventional methods(non-AI), AI (particle swarm optimization), and a hybrid of AI and conventional. However, there are some drawbacks of these methods, which are: [2]:

1) Upon irradiation change, the output of the converter fluctuated and kept fluctuating.
2) At low irradiation, the MPPT is inefficient.

The initial study of DRL provides a promising result compared to the previous methods, as mentioned before. [3], [4], [5]. Even though the implementation of DRL is still under study since the outcome is not met with the model yet [3]. The study is reproducing and extending the MPPT by DRL by Bao et. all [3], Avila et. al. [4] and Gaviria et. al. [6]. The study result is a more stable output based on the TD3 algorithm compared to DDPG and DQN at uniform and non-uniform conditions. This study should be continued and implemented to ensure the benefits of DRL as an MPPT controller.

II. PV System Control Design

A. PV Model and its Components

The PV system for this research is a reproduction of Bao et. al. [3] and Avila et. al.[4] consisting of 3 PV of American Choice Solar, ACS-335-M; each has 80 cells per module, open circuit voltage (V_{oc}) is 49.9V, short circuit current (Isc) is 9A, the voltage at maximum power point (V_{mpp}) is 41.5V, current at maximum power point (I_{mpp}) is 8.07A, temperature coefficient at V_{oc} is -0.36%/°C, temperature coefficient at I_{sc} is -0.36%/°C, light-generated current I_L is 9.0297A, diode saturation current I_0 is 3.1312e-10A, diode ideality factor is 1.0111, shunt resistor R_{SH} is 77.6407 ohm and series resistance R_S is 0.25633 ohm. Each module has a bypass diode if the module has low or no irradiation.

Figure 1 shows the architecture of a PV system where power from PV is transferred to load through a boost converter which is driven by MPPT.

The frequency of PWM is 25kHz the L and C are 2.057mH and 12.9nF respectively, and R as load is 61.71003717 ohm.

979-8-3503-0067-3/23/$31.00 ©2023 IEEE

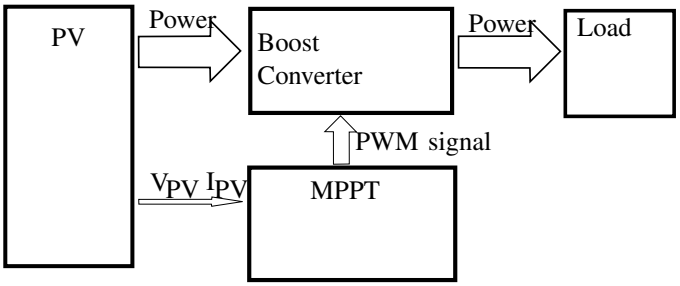

Fig. 1. PV System, PV is ACS-335-M, MPPT by DRL, Resistive Load, MPPT driving the converter by sending PWM signals.

There is a filter capacitor of 3mF. During training episodes, the irradiation and temperatures of PV is randomly initialized according to these conditions:

1) The irradiation values of each PV are randomly selected:
   a) The same value for all from 250W/m^2 to 1000W/m^2 steps 50W/m^2.
   b) Two same values but one is different, all selected from the same range as above.
   c) All three have different values from 150W/m^2 to 1000W/m^2 steps 50W/m^2.
2) The temperature value of all PV is randomly selected from 15°C to 30°C steps 5°C.

Therefore, in total, there are about 23,000 possibilities of initial conditions.

B. Converter Model

There are 3 converter models that are commonly in use for this purpose: Buck, Boost, and Buct-Boost. This study uses a boost converter and the switching is driven by a 25kHz Duty Cycle to the PWM signal module.

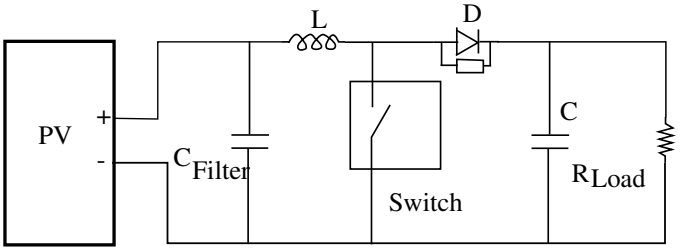

Fig. 2. Boost Converter, PV produces power and filtered by C_{Filter}, L will increase the current loop upon Switch on, D for ensuring current flow toward R_{load}, C for keeping the voltage level when Switch off. R_{load} is a resistive load [7]

The voltage output of PV will be converted by Boost Converter at continued conduction according to the equation 1 [8]:

$$E_c = \frac{T}{T - t_o n} E \tag{1}$$

E_C is the voltage at R_load and E is the V_{PV}, voltage at PV output. T is the frequency of PWM, and t_{on} is the pulse on duration. The converter will increase the PV output voltage based on the t_{on} duration.

C. Methodology of MPPT in PV Systems

At uniform conditions, the voltage and current of PV are at V_{mpp} and I_{mpp} respectively. At non-uniform conditions the PV may have several PV cells disconnected from PV output for safety reasons the current is not drawn from PV, instead, the cells are bypassed and go through a bypass diode for this purpose. This will make the overall PV voltage output decrease significantly.

MPPT will try to find the Global MPP instead of Local MPP, Global MPP is the highest possible power generated and sometimes it is not at the highest possible voltage. [9]

III. DRL as MPPT Controller

A simplified architecture of the PV System utilizing DRL as MPPT Controller is as figure 3 below [9].

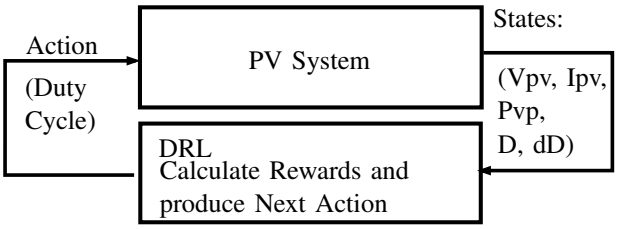

Fig. 3. The environment (PV System) and Actor (DRL system), Environment provides states to be calculated by DRL algorithm to produce rewards and next action. D is the duty cycle and dD is delta D compared to the previous D.

A. Deep Reinforcement Learning and Neural Network Composition

The DRL model free for solving the PV in this simulation is Deep Q-Network (DQN), Deep Deterministic Policy Gradient (DDPG), and Twin Delayed Deep Deterministic Policy Gradient (TD3). For having the sense of similarity, the neural network number of hidden layers and neurons is similar one to the other while keeping the architecture of each. The critic network used 200 neurons per layer and there are 4 hidden layers, the activation function is ReLU. The critic action network uses the *tanh* activation function. For DDPG and TD3, the action network used 200 neurons per layer and there are 3 layers. DQN, DDPG, and TD3 details are explained in the following subsections.

The simulation conditions for DQN algorithm are a revision of Gaviria et. al. [6] codes. The revision is required since there are functions used in Gaviria's code which is not recommended anymore for the simulation purpose based on Matlab recommendations [10]. Therefore the code is restructured, adjusted, and rewritten by new recommended functions.

The DDPG and TD3 Agents were created following the neural network structure of the DQN Agent. As stated previously, the DQN code is a revision of Gaviria's[6], however, DDPG and TD3 have no published code available. Bao et. al. [3] provide brief information on the DDPG algorithm structure but not the code. Therefore the code for DDPG Agent [11]

and TD3 Agent [12] were created according to the Mathworks recommendation structure while DDPG is following the recommendation from Bao et. al. [3].

Training episode for all methods is limited to 10000. Lastly, the GPU is used as a calculating device.

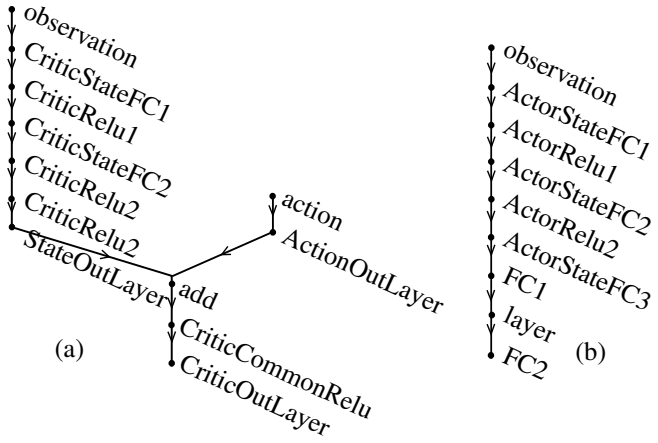

Fig. 4. (a) The Critic Network used in all DRL models (b) The action network used in DDPG and TD3

B. DQN as MPPT Controller

The methodology of DQN is describe in pseudo-code as Algorithm 1, [13] and modified by Bao et. al. [3]:

Algorithm 1 Algorithm for Deep Q-Network

Input: states
Output: action

Initialize replay memory D with a defined capacity N
Randomly initialize critic network Q(s, a|θ) with weight θ
Initialize target network $Q^{'}$(s,a|$\theta^{'}$) with weights $\theta^{'} \leftarrow \theta$
for episode = 1 to M **do**
  Initialize state s
  for t=1 to T **do**
    Following ϵ-greedy policy,
    select a_t= $\begin{cases} \text{a random action, if probability} \leq \epsilon \\ argmax_a \text{ Q}(s_t, a_t|\theta), \text{otherwise} \end{cases}$
    Execute action a_t to get reward r_t and observe the next states s_{t+1}
    Store transition (s_t, a_t, r_t, s_{t+1}) in D
    Sample a random mini-batch of (s_t, a_t, r_t, s_{t+1}) from D
    Set y_j = $\begin{cases} r_j, \text{ if episode terminates at step j+1} \\ r_j + \gamma \ max_a \ Q(s_{t+1}, a_{t+1}; \ |\theta^{'}), \text{otherwise} \end{cases}$
    Perform a gradient descent step to minimize the loss function for updating the critic network $L = \frac{1}{N}\sum_j (y_j - Q(s_j, a_j|\theta^Q))^2$, w.r.t. the network parameter θ
    Update the weights of the target network every C steps
  end for
end for

Actions are discrete values: [-0.03 -0.01 -0.005 -0.001 0 0.001 0.005 0.01 0.03], γ (discount factor) is 0.9, mini-batch size is 512, the learning rate is 0.0001 and adam optimizer applied. Double DQN is chosen as the method since it reduces the overestimate problem in DQN. [3]

C. DDPG as MPPT Controller

The algorithm is selected as the actor-critic representative for off-policy, model-free DRL [14] [3]. The pseudo-code for DDPG is Algorithm 2

Algorithm 2 Algorithm for DDPG

Randomly initialize critic network Q(s, a, $|\theta^Q$) and actor network $\mu(s|\theta^\mu)$ with weight parameters θ^Q and θ^μ, respectively.
Initialize target network Actor Q'(s, a, $|\theta^{'}_Q$) and Critic $\mu^{'}$(s $|\theta^{'}\mu$) with weight parameters $\theta^{Q'} \leftarrow \theta^Q$ and $\theta^{\mu^{'}} \leftarrow \theta^\mu$, respectively
Initialize experience replay memory D to a defined N
for episode = 1 to M **do**
  Initialize the random process $\mathbb{N}$ in the action exploration strategy.
  Observe initial states s_1
  for t=1 to T do **do**
    Select an action a_t= $\mu_t(s_t|\theta^\mu) + N$, based on the current policy $\mu(st)$ and exploring noise $\mathbb{N}$
    Execute action a_t in the environment to get reward r_t and the new state s_{t+1}
    Save transition (s_t, a_t, r_t, s_{t+1}) in D
    Sample random mini-batch of *Nth* transitions (s_t, a_t, r_t, s_{t+1}) from D
    Set $y_j = r_j + \gamma Q'(s_{j+1}, \mu'(s_{i+1}|\theta^{\mu'})|\theta^{Q'})|\theta^{Q'}$
    Update online critic network by minimizing loss: $L = \frac{1}{N}\sum_j (y_j - Q(s_j, a_j|\theta^Q))^2$, w.r.t. the network parameter θ
    Update the actor policy actor-network the sampled policy gradient.
    Update all target actor networks and target critic networks
  end for
end for

The critic and actor-network configurations are stated in Figure 4. The state element is limited as follows:

1) V_{PV}: -inf to inf
2) I_{PV}: -inf to inf
3) Duty Cycle: from 0 to 1.0
4) Delta of Duty Cycle: from -1.0 to 1.0

The action elements are limited from 0.0 to 1.0 (duty cycle values). The Target Smooth factor is 0.001, the discount factor is 1.0, the mini-batch size is 512, and the experience buffer length is 1e6. The Adam optimizer is applied to the network, the learning rate is 0.0001, and the gradient threshold is 1.

D. TD3 as MPPT Controller

The methodology of TD3 is describe in pseudo-code as Algorithm 3, modified from Fujimoto et. al. [15]:

Algorithm 3 Algorithm for TD3

Initialize critic network $Q_{\theta_1}, Q_{\theta_2}$, and actor network π_ϕ. with random parameters θ_1, θ_2, ϕ
Initialize target network $\theta_1' \leftarrow \theta_1, \theta_2' \leftarrow \theta_2, \phi' \leftarrow \phi$
Initialize replay memory D
for t = 1 to T do **do**
  Select action with exploration noise a $\sim \pi_\psi(s) + \epsilon, \epsilon \sim \mathbb{N}(0, \delta)$ and observe reward r and new state s_{t+1}
  Store transition tuple (s_t, a_t, r_r, s_{t+1}) in D
  Sample mini-batch of N transitions (s_t, a_t, r_r, s_{t+1}) from D
  $\tilde{a} \leftarrow \pi_{\phi'} + \epsilon, \epsilon \sim$ clip($\mathbb{N}(0,\tilde{\delta})$,-c,c)
  $y \leftarrow r + \gamma\ min_{i=1,2}\ Q_{\theta'}\ (s', \tilde{a})$
  Update critics $\theta_i \leftarrow argmin_{\theta_i} N^{-1} \Sigma (y - Q_{\theta_i}(s,a))^2$
  if t mod d then **then**
    Update ϕ by the deterministic policy gradient:
    $\nabla_\phi J(\phi) = N^{-1} \Sigma \nabla_a Q_{\theta_1}(s,a)|_{a=\pi_\phi(s)} \nabla_\phi \pi_\phi(s)$
    Update target networks
    $\theta_i' \leftarrow \tau\theta_i + (1-\tau)\theta_i'$
    $\phi' \leftarrow \tau\phi + (1-\tau)\phi'$
  end if
end for

The hyper-parameters are the same as DDPG.

IV. Simulation and Analysis

A. Simulation Conditions and Results

The training was on an i7 Intel computer with 16GB memory capacity (expandable by swap memory on hard drive up to 200GB), NVidia RTX 2060 using Matlab R2023a. DQN training took time around half of DDPG and TD3, the memory usage of DDPG is the highest compared to the two others, which is 120GB, and the TD3 and The DQN about 33GB. The agent was then tested against two extreme PV conditions: 1000W/m^2 and 250W//m^2 representing clear and mostly cloudy days, the results are shown in the figures 5 and 6 also in tables I and II.

There is still fluctuation on all power signals and they are all compared at 1000W/m2 irradiation and also at 250W/m2 one.

The duration compared between the results is the last 0.1s of the signals for it is considered all signals have been in steady state conditions. There are 41,436 samples during a duration of time 0.3 seconds to 0.4 seconds with time sampling is approximately 6.15µs.

B. Analysis of The Results

The training period for the TD3 is the longest while DQN is the fastest for TD3 structure has more neural networks compared to DDPG and DQN, therefore training time is not compared.

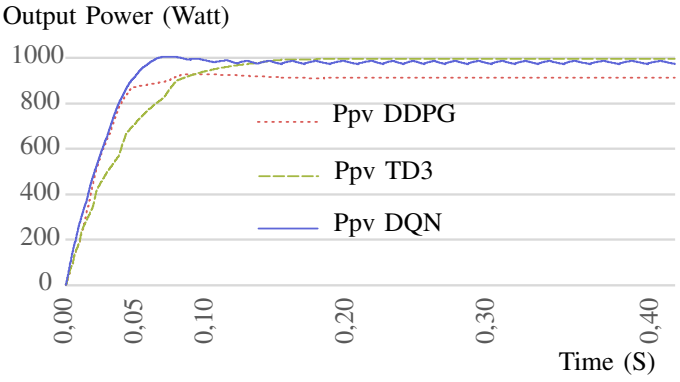

Fig. 5. Comparison of Output power of PV (P_{PV}) by DRL MPPT trained based on DDPG, TD3 and DQN algorithm. All PV is received irradiation 1000W/m^2

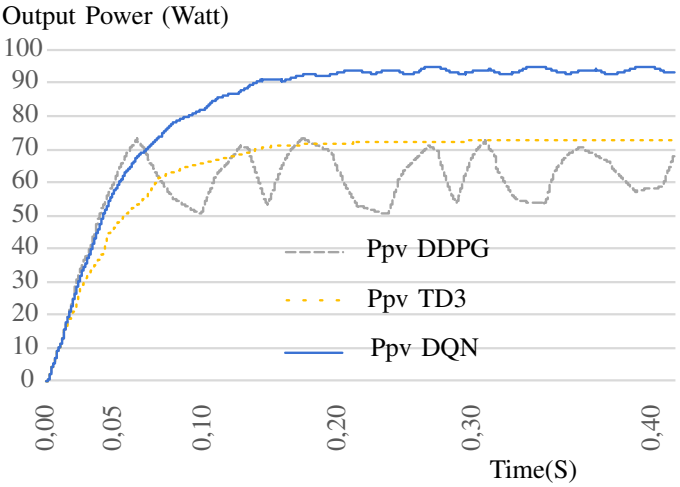

Fig. 6. Comparison of Output Power of PV (P_{PV}) by DRL MPPT trained based on DDPG, TD3 and DQN algorithm while all PV has irradiation 250W/m^2

TABLE I
Comparison of DQN, DDPG, and TD3 at Uniform Condition from 0.3s to 0.4s Period

	Irradiation at 1000W/m^2		
	DQN (W)	***DDPG (W)***	***TD3 (W)***
Mean	980.6801	913.3411	996.7506
SDev	4.043671	0.03989	0.029259

TABLE II
Comparison of DQN, DDPG, and TD3 at Uniform Condition from 0.3s to 0.4s Period

	Irradiation at 250W/m^2		
	DQN (W)	***DDPG (W)***	***TD3 (W)***
Mean	93.76509	62.42913	72.5331
SDev	0.738881	5.805285	0.021484

The main target of the research was comparing the power output produced by the converter circuit (P_{PV}) which is driven by DRL Agents, DQN Agent, DDPG Agent and TD3 Agent at given PV conditions (Irradiation on each PV and temperatures of the PV panels). The environmental conditions of PV were the same and each agent has same number of training episodes.

Based on the output power, at PV irradiation is 1000W/m^2, TD3 produced average maximum output power 8.37% higher than DDPG and 1.61% higher than DQN. At PV irradiation is 250W/m^2, average maximum output power of TD3 is higher 13.93% than DDPG but lower 29.27% than DQN.

Based on the power signal fluctuation at 0.1second period, TD3 has the least fluctuated power output, the standard deviation of TD3 power signal is 0.02 on high and low irradiation. While DDPG and DQN have higher fluctuations (standard deviation).

Standard deviation of DQN is 0.74 at cloudy day or low irradiation and DDPG is 0.04 at clear day or high irradiation and standard deviation of DQN's power signal is 4.04 at clear day and DDPG is 5.8 at cloudy day.

The response time of each curve to achieve its steady state condition is longer at 250W/m^2 compared to at 1000W/m^2. For DQN, it is about 2 times longer (0.05s to 0.1s), DDPG is nondeterministic since too fluctuated at 250W/m^2 and for TD3 it is about 1.5 time longer (0.1s to 0.15s). The response time is essential during a quick PSC day.

V. Discussion

The study found TD3 is the promising candidate as MPPT controller for the stability and efficiency in power transfer and also for the time response for PSC. The study had been carefully designed to be comparable to previous research and tested on 10000 episodes for training purpose of the agent. The study confirmed the previous research and extended to TD3 algorithm for TD3 is a revision of DDPG. The simulation done also found that TD3 is less memory consuming compared to DDPG.

At the moment a training consist of 100000 episodes is ongoing and may become a reference for other DRL or methods to achieve a stable and efficient MPPT controller or even as reference for implementation in the field.

Next, it is suggested to have further study covering control of each element of the PV System to gain optimum benefit of DRL in the system also effect of noise in the system.

VI. Conclusion

In this paper, DRL algorithm DQN and DDPG are implemented as for MPPT. All algorithm have almost similar neural network architecture and number of training episodes. TD3 provides a more stable power transfer compared to DQN and DDPG, either in 1000W/m^2 and 250W/m^2 irradiation and highest efficiency in high power transfer. At 1000W/m^2 condition, TD3 produced output power 8.37% higher than DDPG and 1.61% higher than DQN. At 250W/m^2 TD3 is higher 13.93% than DDPG but lower 29.27% than DQN.

On both condition TD3 has the least fluctuated power output, the standard deviation is 0.02 on both conditions. DQN is 4.04 at clear day and DDPG is 5.8 at cloudy day. Next, it is suggested to have further study covering control of each element of the PV System to gain optimum benefit of DRL in the system.

***Abstract*—Photoplethysmography (PPG), a non-invasive method to measure health parameters, is highly dependent on signal quality to produce accurate and reliable measurements. Wearable PPG signals are susceptible to various factors that can degrade their signal quality. To address this issue, we present an algorithm for reducing errors by assessing signal quality and combining information from multichannel PPG to estimate heart rate (HR), interbeat interval (IBI) and heart rate variability (HRV) parameters using the time domain approach. Our method works by dividing into multiple 10 s nonoverlapping segments, assessing the quality of segments from multiple channels within the same period, selecting the best segments that are acceptable in terms of quality via template matching. Our proposed method significantly improves the number of acceptable samples (65.32%) and reduces the mean absolute error (MAE) for the estimation of HR and the average NN interval (AVNN) by 62.20% and 78.60%, respectively, compared to the single channel PPG. Overall results suggest that signal quality assessment from multiple channels can be used to improve the accuracy of the estimation of PPG-derived parameters from wearable devices.**

I. Introduction

Photoplethysmography (PPG) is implemented in various wearable devices such as wrist-worn smartwatches and finger-worn smart rings. Unlike fingertip PPG signals that are normally acquired in clinical settings where the subject is sitting still, wearable PPG devices are designed for daily activities in which many movements are involved. These movements can introduce noise and motion artifacts. Several approaches have been proposed to detect such artifacts [1], [2]. The motion artifact degrades the signal quality, in some cases obscuring pulse peaks and distorting the pulse wave shape. This can significantly reduce the accuracy of the derived health parameters.

To address the above issue, multiple preprocessing steps have been developed and widely used, such as detrending, bandpass filtering, and denoising using accelerometer sensors [3]. The preprocessed signals are then fed into the algorithms to estimate health parameters. Generally, the algorithms can be categorized into time domain methods and frequency domain methods. Time domain methods involve peak detection and calculation of the periods between the peaks in which health parameters can be derived. Frequency domain methods transform PPG signals into the frequency domain and typically identify the frequency with the highest peak to obtain the desired health parameters. Frequency domain methods are more robust than the time domain counterparts, since noises can be directly removed by excluding high-frequency noise in the frequency domain. However, frequency domain methods limit the capability of obtaining other parameters such as the interbeat intervals (IBIs).

Time domain methods measure the period between consecutive peaks in the PPG signal. Numerous peak detection methods have been investigated in the past [4], [5]. Signal quality usually varies throughout the signal and there are segments that have poor quality. When these segments are fed into peak detection algorithms, peaks can be missed or falsely detected, producing erroneous parameter estimations. Studies implementing these peak detection methods [6], opted to discard segments with flat lines due to sensor disconnection. There needs to be a way to determine whether or not the result of the time domain method is acceptable for further analysis.

In this paper, we propose a signal quality assessment (SQA) algorithm to determine whether a segment is usable or not by utilizing PPG signals from multiple channels. We select channels from different wavelengths that had been used in the past for PPG signals. The three channels that are widely used are green [7], [8], red [9], [10], and infrared [9]–[11]. Multichannel approaches have been previously developed, such as using data fusion to estimate respiratory rate, delivering promising results [12]. Each channel has its own advantages and disadvantages. For example, green PPG signals are more robust to motion artifacts but are affected by melanin, as green light only reaches the superficial part of the skin [13]. On the other hand, red and infrared light can penetrate deeper into the skin, meaning that they are less likely to be affected by melanin but are unfortunately more vulnerable to motion artifacts [13].

The remainder of this paper is organized as follows. Section II describes the methods which include data collection, proposed algorithm, signal quality assessment, and health parameters to be estimated. Section III presents and discusses

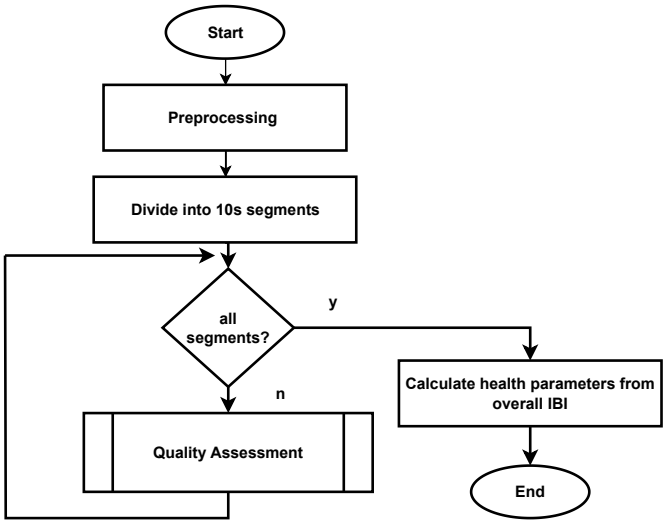

Fig. 1. The proposed signal quality asessment (SQA) algorithm

the performance evaluation of the proposed algorithm on the collected data. Finally, conclusions are drawn in Section IV.

II. Methods

A. Data Collection

Data were collected from 31 healthy subjects (17 males and 14 females) with age ranging from 20 to 24 years old. All subjects provided their informed consent following the guidelines established in the Declaration of Helsinki. The ethical approval was obtained from the Research Ethics Committee of the Bandung Institute of Technology, Indonesia (No. KEP/II/2022/X/M130723NA/PSPT). Electrocardiogram (ECG) signals were measured with the Polar H10 device at a sampling frequency of 100 Hz. PPG signals were acquired using our custom wrist-worn PPG device, equipped with the max30101 sensor with a sampling rate of 60 Hz. Three PPG channels collected green, red, and infrared wavelength PPG signals. The PPG and ECG signals were obtained simultaneously for 90 seconds. As a reference, we used IBI data obtained by the built-in function provided by Polar H10.

B. Proposed Algorithm

Fig. 1 shows the proposed SQA algorithm. All PPG channels were interpolated using cubic spline interpolation from 60 Hz to 100 Hz to ensure the same sampling frequency as the ECG. Interpolated signals were detrended to remove baseline wander as well as low-frequency noise. The signals were then filtered with a bandpass filter to keep frequency content between 1–8 Hz. Next, the signals were divided into multiple segments, each with a length of 10 s ($\sim$1000 samples per segment). IBI estimation and quality assessment were performed on each segment. Finally, the resulting IBIs were used to calculate health parameters. All signal processing was performed in Python with the help of Neurokit2 library [14].

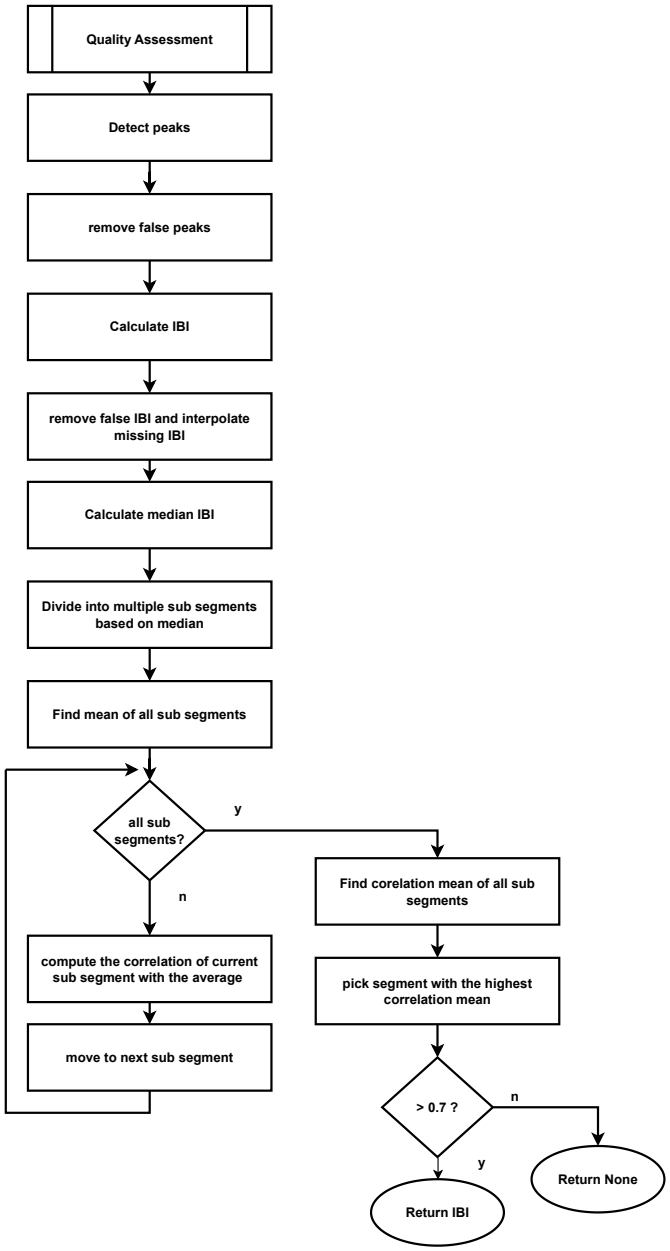

Fig. 2. Signal quality assessment (SQA) algorithm

C. Signal Quality Assessment

Fig. 2 illustrates the steps of the signal quality assessment (SQA) algorithm. IBIs were calculated using a time domain method which consists of detecting pulse wave peaks and then calculating IBIs as the time delays between successive peaks. We used qppg algorithm for peak detection because it was found to yield the highest accuracy particularly during movement [6], [15]. The qppg algorithm detects systolic upslopes that are identified with adaptive thresholding and with the help of a slope sum function, and calculates the total magnitude of upslopes in the previous 0.17 s. In our study, we observed that in some cases, it overestimates the number of peaks where additional peaks come from noise. Fig. 3 shows

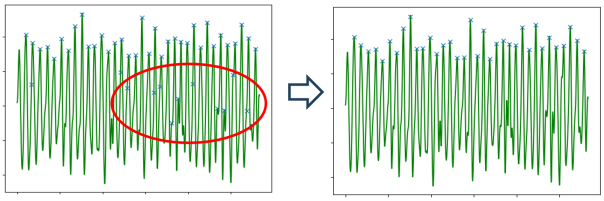

Fig. 3. Removal of false peak

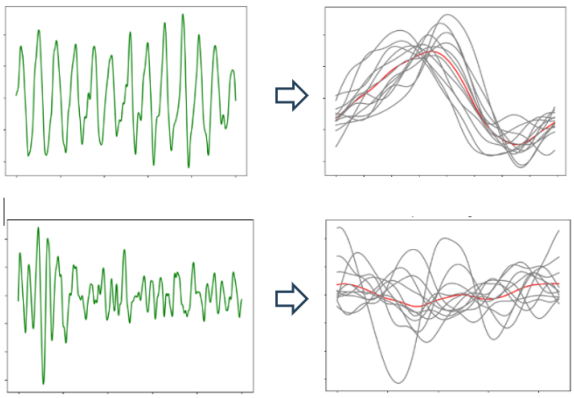

Fig. 4. Template matching

an example of peaks being falsely detected.

To solve the problem of false peak detection, we employed straightforward peak removal method. We first collected the data from 20 samples before and 20 samples after the current peak. If both the former and the latter were lower than the corresponding peak, the peak was kept. However, when the condition was not met, the peak was marked as false and rejected. Next, we calculated the IBI using the already confirmed peaks by using the difference in time between adjacent peaks. The resulting IBIs exhibited variations and sudden changes (spiky). While IBIs could vary over time [16], some of these variations are were too large. Falsely detected peaks rather than actual PPG systolic peaks contribute to this issue. Therefore, we smoothed the resulting IBIs by removing IBIs with differences greater than 0.15 s from the median of the overall IBI within this segment. In the cases where there were at least four IBIs left, we interpolated the number of IBIs to have the same number of IBIs as before the false IBI was removed.

Template matching [17] [18] searches for regularity within the PPG segment. It is based on the assumption that the shapes of pulse waves in high-quality PPG signals are almost consistent throughout the signal. In Fig. 4, we present the differences between high- and low-quality PPG segments. Grey lines represent individual pulse wave, while the red line is the average of all the pulse waves within the segment. High quality PPG segments have a regular shape, resulting in grey lines that overlap each other. On the contrary, low-quality segments have a variety of shapes that appear to be random and have low similarity. The median IBI was calculated for each 10 s PPG segment. The median was then used to divide the segment into multiple subsegments. We proceeded to estimate the mean IBI of all the sub-segments and used it as the reference shapes. We computed the correlation from each pulse wave with that of the reference shape and the average all the correlations. We found that the best threshold for accepting a PPG segment is 0.7 after experimenting with different threshold numbers, which was high enough to prevent low quality signals from passing in while still allowing imperfect signals with slight noise to be used as input. We selected one out of the three signal segments (green, red, and infrared) in the same period that exceeds the 0.7 minimum threshold and scores the highest. If all three segments had scores below the threshold, the segments were discarded.

TABLE I
HEALTH PARAMETER

Parameter Name	Definition
HR	Heart rate calculated from AVNN
AVNN	Average of NN intervals
SDNN	Standard deviation of NN intervals
RMSSD	Root Mean square of successive Differences
SDSD	Standard seviation of successive Differences
PNN50	Proportion of successive difference that are over 50 ms
PNN20	Proportion of successive difference that are over 20 ms

TABLE II
PERCENTAGE OF ACCEPTED SAMPLES

Signals	Accepted Samples	Percentage (%)
Green	163	38.72
Red	127	30.17
Infrared	221	52.49
Combined	275	65.32

III. RESULTS AND DISCUSSION

A. Low Quality Signal Identification

Health parameters that were estimated in this study along with their definition are shown in Table I. In total, 421 samples were gathered from 31 subjects. Some samples were in low-quality which could yield large errors. In our algorithm, if all the segments from the collected signals do not surpass the threshold in all periods, then the corresponding sample is discarded. For comparison, we also present the number of acceptable samples from three different channels computed individually using the proposed SQA algorithm. Based on Table II, we can see that the percentage of samples categorized as high quality increases when using multiple channels compared to single channel. The infrared channel produced the highest percentage of the accepted samples, but was still lower than when all three channels were combined with the percentage of 65.32%. Our results showed that multichannel

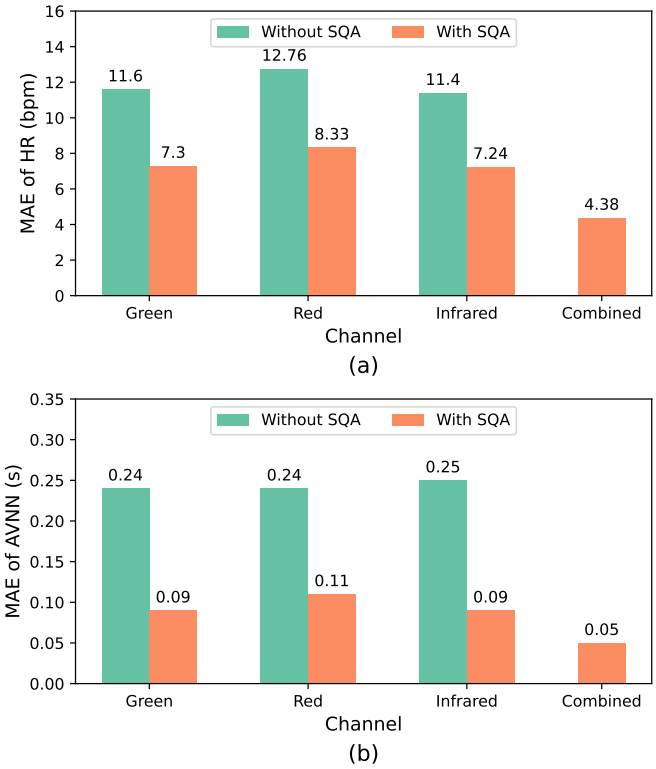

Fig. 5. MAE for (a) HR and (b) AVNN

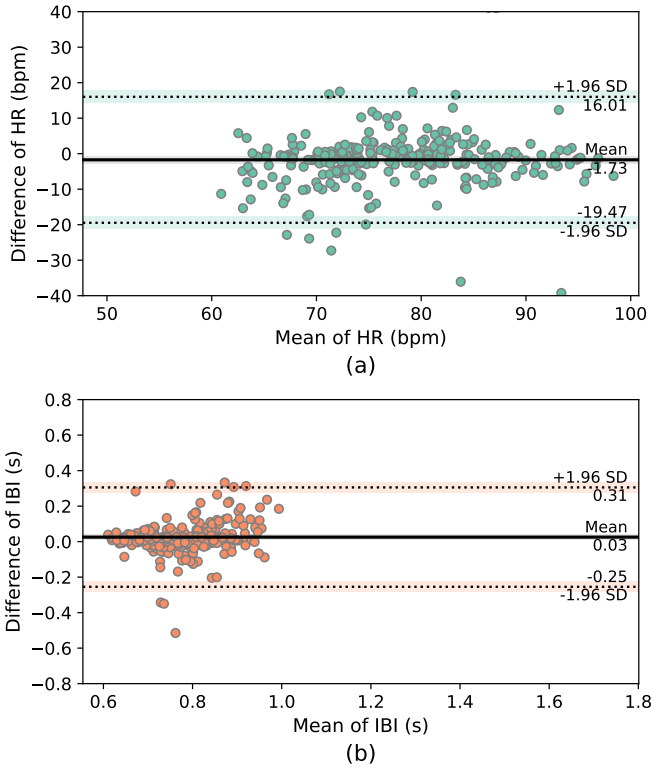

Fig. 6. Bland-Altman plot for (a) HR and (b) IBI from combined channels with signal quality assessment.

approach decreases the amount of data loss due to noise. This is beneficial in real-world applications where it is desired to keep as much data as possible for analysis.

B. Estimation Improvement

Fig. 5(a) shows mean absolute error (MAE) comparison from single channel (green, red, or infrared) and multichannel (combination of all the three signals) with and without SQA algorithm. It is shown that using the SQA on a single channel measurement alone was able to reduce the error by at least 34.72%. Overall, by combining all the PPG signals with SQA to select the best segment, we were able to reduce the MAE by 62.20%. AVNN is used to calculate HR with the following formula.

$$\mathrm{HR} = 60/\mathrm{AVNN} \tag{1}$$

Improvement of HR estimation was caused by the improvement of AVNN. From Fig. 5(b), we can see that the MAE of AVNN reduced with the use of SQA on a single channel source by at least 54.86%. The combined use of all three channels with SQA reduced the MAE by 78.60%. The MAEs were 0.24 s, 0.24 s, and 0.25 s for green, red, and infrared signal, respectively. The MAE obtained from SQA was as small as 0.05 s, which indicates that the proposed SQA algorithm successfully reduced the error by 44%. Looking into the details, the Bland-Altman plot in Fig. 6 illustrates the distribution of these errors. These outliers were low quality data that had not been marked as low quality by the algorithm. When the algorithm mistakenly identifies low quality signals as high ones, it could produce a large error .

C. Estimation of HRV Parameters

The good improvement shown in HR and AVNN encouraged us to apply the proposed SQA algorithm for the estimation of HRV parameters, which are typically calculated for extended periods such as 24 hours. The currently used dataset was only taken from 90 s measurements, which falls into ultra-short measurement category. Previous studies were conducted on ultra-short measurements [19] [20] and motivated us to evaluate our SQA algorithm on ultra-short term HRV measurements.

Fig. 7 illustrates the MAE obtained from the estimation of five HRV parameters: RMSSD, SDNN, SDSD, PNN20, and PNN50. From Fig. 7(a), the MAE of RMSSD, SDNN, and SDSD were above 0.1 s or 100 ms. The algorithm performed best (lowest MAE) when estimating SDNN. Fig. 7(b) illustrates the result in percentage form for PNN20 and PNN50. PNN50 and PNN20 measure the proportion of changes in NN interval that are above 50ms and 20ms, respectively. It is clear that for both PNN20 and PNN50, the error is large with more than 20%. These results indicate that despite the good improvement on HR estimation accuracy, it is still not enough to yield reliable HRV estimation with values typically less than 100 ms.

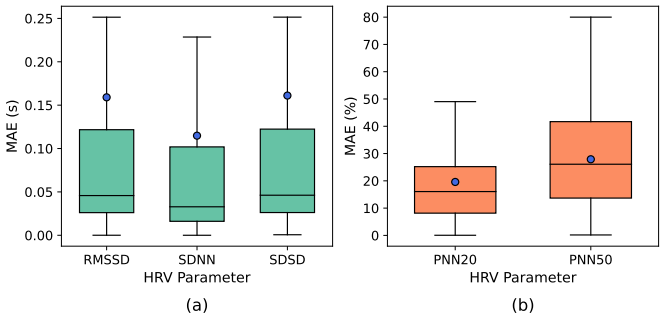

Fig. 7. Boxplot of MAE for HRV parameter estimation: (a) RMSSD, SDNN, and SDSD (b) PNN20 and PNN50

IV. Conclusion

We have presented a signal quality assessment (SQA) algorithm from wearable multichannel (combination of green, red, and infrared) PPG signals. We demonstrate that our proposed algorithm can improve the accuracy of health parameter estimation using our in-house dataset. It reduced the MAE by 62.2% for HR and 78.6% for AVNN compared to the result from individual signal without SQA. However, it was still not good enough to be used for measuring HRV in ultra-short duration. For future work, we suggest further development of the algorithm to allow for more accurate HRV measurement in low quality signals and in ultra-short duration.

***Abstract*—This study introduces a novel muscle activation analysis based on surface electromyography (sEMG) signals to assess the muscle's after-fatigue condition. Previous studies have mainly focused on the before-fatigue and fatigue conditions. However, a comprehensive analysis of the after-fatigue condition has been overlooked. The proposed method analyzes muscle fatigue indicators at various maximal voluntary contraction (MVC) levels to compare the before-fatigue, fatigue, and after-fatigue conditions using amplitude-based, spectral-based, and muscle fiber conduction velocity (CV) parameters. In addition, the contraction time of each MVC level is also analyzed with the same indicators. The results show that in the after-fatigue condition, the muscle activation changes significantly in the ways such as higher CV, power spectral density shifting to the right, and longer contraction time until exhaustion compared to the before-fatigue and fatigue conditions. The results can provide a comprehensive and objective evaluation of muscle fatigue and recovery, which can be helpful in clinical diagnosis, rehabilitation, and sports performance.**

***Index Terms*—Surface electromyography, maximal voluntary contraction, conduction velocity, EMG, power spectral density.**

I. Introduction

Surface electromyography (sEMG) is a non-invasive technique to measure the electrical activity of skeletal muscles. Surface EMG signals can provide valuable information about muscle fatigue, defined as the decrease of maximal force output to maintain or repeat tasks by muscles [1]. Muscle fatigue can affect the performance and health of muscles in various fields such as medicine, sports, rehabilitation, ergonomics, and human-machine interaction [2]–[4]. Therefore, assessing muscle fatigue based on sEMG signals is of great significance and especially interesting to researchers and health professionals.

Surface EMG signals are a valuable tool to evaluate muscle fatigue, and their applications in life and industrial fields are promising and diverse. However, assessing muscle fatigue based on sEMG is complex because it involves many complex factors, such as muscle type, contraction type, electrode placement, signal processing methods, and fatigue indices [5]. In addition, surface EMG signals are often affected by noise from various sources, such as motion artifacts, skin perspiration, skin impedance, and electromagnetic interference [6], [7]. Therefore, robust and reliable methods are in demand to extract meaningful features from sEMG signals and to classify the states of muscles before, during, and after muscle fatigue. Feature extraction of sEMG signals is a method of extracting useful information from signals under different muscle conditions. Muscle fatigue is usually identified by the decrease of frequency domain indices and time-frequency domain indices and the increase of time domain indices. The traditional approach to acquiring sEMG signals is still commonly used in physiological and clinical studies, based on a pair of electrodes placed on the skin over the muscle. However, the acquired signal depends on the location, the distance between electrodes, the size of the electrode pair, and the area along the muscle fiber, which can lead to very different spectral characteristics and amplification [5], [6].

Initially, sEMG signal features can be divided into three domains: time domain, frequency domain, and time-frequency domain. However, in the past 40 years, a large number of parameters extracted from sEMG signals to evaluate muscle fatigue have been developed. Currently, sEMG features are divided into amplitude-based parameters, spectral-based parameters, non-linear parameters, and muscle fiber conduction velocity (CV) estimation [8], [9]. For the classical bipolar measurement method, using methods based on more than two electrodes arranged in series allows collecting sEMG signals along the vertical or horizontal axis of the muscle [10]. A relatively recent approach includes using multiple electrode groups arranged in one- or two-dimensional arrays. In addition, the two-dimensional electrode array can determine the distribution of sEMG amplitude and describe the spectrum over the entire skin area covering the muscle [11]. Multi-channel sEMG signals also allow for more accurate and reliable estimation of CV [12]. Previous studies have investigated the changes in power spectral density (PSD) of sEMG signals during different muscle contraction and load levels. For example, [8], [13] examined the PSD of sEMG signals at various maximal voluntary contraction (MVC) levels and found that the PSD shifted to lower frequencies with increasing MVC. And [9] used a linear array sEMG to study the relationship between CV and the shift of PSD over time with different load levels. They observed that the CV decreased, and the PSD shifted to

*Corresponding Author

lower frequencies as the load increased.

Most studies mentioned above have mainly focused on the before-fatigue and fatigue conditions, but the after-fatigue condition has not been well explored. Moreover, previous studies exploited only several separate parameters, which did not fully interpret the objective and comprehensive evaluation of muscle in different conditions. The main contributions and findings in this work are summarized as follows:

- A novel analysis that analyzes all muscle fatigue indicators, such as Root mean square, Mean frequency, Power spectral density, and CV at various maximal voluntary contraction (MVC) levels. In contrast, the previous works analyzed only a few fatigue indicators at a few MVC levels and muscle conditions [14].
- The first attempt to analyze after-fatigue conditions compared to before-fatigue and fatigue conditions. Note that the previous studies only focused on before-fatigue and fatigue conditions as shown in [8], [9], [13]. Such analysis and comparison showed a significantly increasing contraction time of the after-fatigue condition until exhaustion, and this phenomenon was partially explained.

The rest of this work is constructed as follows. Section II presents the signal acquisition protocol and our analysis method, and then Section III discusses the experimental results. Finally, Section IV concludes the paper.

II. Materials and Methods

A. Signal acquisition protocol and data pre-processing

A monopolar sEMG signal was collected by the two-dimensional 64-electrode sEMG sensor, divided into thirteen rows and five columns, with an inter-electrode distance of eight millimeters and a sampling frequency of 2048 hertz. The sensor provides five groups of differential signals with thirteen electrodes along with the Biceps Brachii muscle group. A force signal over time is measured from the force gauge collected with each MVC level, as shown in Fig. 1 (A). In addition, the representation of the sensor matrix and the direction of signal propagation is described in Fig. 1 (B). The sEMG signals from all electrodes obtained from the MVC levels were digitally filtered (20 Hz-400 Hz) to reduce noise.

The data was collected on ten healthy subjects: three women and seven men (mean age 24, standard deviation 1.5 years). The MVC of an individual subject was defined as the average value of three times producing the maximum force, which separated every five minutes. After determining the MVC, the tests can be conducted at different force levels, expressed as a percentage of MVC. The subject should hold the force for at least ten seconds if possible. The experiment starts with a test at 10% of MVC so the subject can learn to maintain a certain force level. Furthermore, the process continues with the random order tests at 20%, 40%, 60%, and 90% of MVC, an exhaustion test at 70% of MVC, and a final test at 10% of MVC. Each subject takes a rest of five minutes between two consecutive tests. As such, the states before muscle fatigue include 10%MVC, 20%MVC, 40%MVC, 60%MVC, and 90%MVC, while the state during muscle fatigue is 70%MVC and the state after muscle fatigue is 10%MVC.

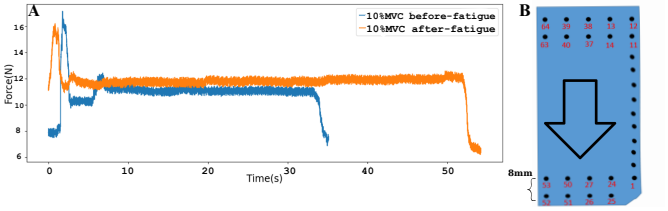

Fig. 1. (A) Representation of the longer force's contraction time until exhausted. (B) The matrix sensor is used in signal acquisition.

B. Amplitude-based parameters

Root mean square (RMS) is the main parameter used to investigate the amplitude of the sEMG signal. The formula for RMS is as follows:

$$RMS = \sqrt{\frac{1}{N}\sum_{n} x_n^2}, \tag{1}$$

where x_n are the values of the sEMG signal, and N is the number of data samples. RMS is believed that during maximal isometric contractions, amplitude falls progressively, in parallel with the decrease in force [15].

C. Spectral-based parameters

Two characteristic frequencies that have been used to quantify changes in spectral content based on the Fourier transform are the mean frequency (MNF) and the median frequency (MDF) of the power spectrum [16]. MDF is calculated as follows:

$$MDF = \int_{f_1}^{f_{median}} PS(f)df = \int_{f_{median}}^{f_2} PS(f)df, \tag{2}$$

while MNF is calculated as follows:

$$MNF = \frac{\int_{f_1}^{f_2} f.PS(f)df}{\int_{f_1}^{f_2} PS(f)df}, \tag{3}$$

where $PS(f)$ is the power spectrum calculated from the Fourier transform, f_1 and f_2 determine the lowest and highest frequency of the signal bandwidth, usually ranging from 20 hertz to 400 hertz. MDF and MNF are related to the change in CV and have been shown in isometric contractions that MNF will shift to lower frequencies during fatigue [17].

D. Conduction velocity estimation

The muscle's CV was initially calculated by placing electrodes along the muscle. However, this method can be biased in estimating CV when muscle fibers are not placed in a parallel plane. Moreover, electrodes placed on an undefined muscle domain can lead to misleading information [18]. Recently, multi-channel sEMG signals allowed more accurate estimation of CV both at the global level of the muscle and CV of individual motor units [15]. Therefore, this study conducted CV

estimation based on the multi-channels maximum likelihood estimation algorithm [19]. First, three single differential sEMG signals were selected to remove the mean value. Then, the algorithm calculates two double-differential sEMG signals and tries to maximize the likelihood delay function for observing the delay time between the two signals. CV was obtained after calculating the delay time by dividing the electrode distance by the delay time. The formula for calculating CV is as follows:

$$CV = \frac{d}{\theta}, \tag{4}$$

where d is the distance between two electrodes, θ is the delay time between two electrodes. The algorithm is described in more detail in [19].

CV parameter is related to the properties of the fiber membrane, fiber diameter, and contraction properties of the fiber. Therefore, measuring CV degradation is considered as the strongest indicator of muscle fatigue [20]. In addition, changes in the CV in muscle fatigue have a profound impact on the motor unit action potential waveform and, therefore, affect both amplitude parameters and spectral parameters extracted from sEMG, as analyzed in [21], [22]. Previous studies [23], [24] have also shown that CV is reduced due to the consequences of local metabolic changes in active muscles, mainly due to H+ and K+ distribution in the sarcolemma.

E. The proposed after-fatigue analysis methods

One of the novel aspects of this analysis method is that it calculates all indicators on the sEMG signal according to MVC levels and contraction time. While in [2] only shown a few indicators. The amplitude parameters (RMS) and spectral parameters (MNF) were obtained from the entire sEMG signal for each MVC level, excluding the noise parts at the beginning and end. The parameters were averaged over all signals. The electrodes' signals were visualized through a single differential filter to determine the innervation zone, as shown in Fig. 2.

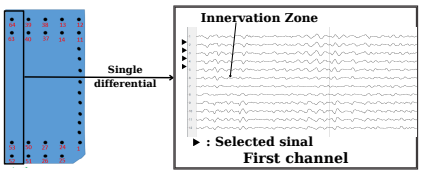

Fig. 2. Representation of Innervation zone and signals selection.

The multi-channel algorithm mentioned earlier estimated the CV with selected sEMG signals. The CV value will be accepted if the correlation coefficient between adjacent signals is more than 0.75. The estimated CV value of each MVC level was averaged over channels.

Furthermore, according to the analysis method of contraction time, each selected signal was divided into intervals, spaced 1000ms and 500ms long, which is believed to be stationarity. MNF and RMS obtained from each MVC level were averaged over all selected signals. The PSD representation of the signal was divided into three intervals, each with a length of 1000ms. "Onset" is taken at the beginning, "Middle" is taken in the middle, and "End" is taken at the end of the signal. These intervals allow capturing the changes in sEMG parameters over time and comparing them across MVC levels.

Finally, CV was calculated on each selected signal with segments 500ms long and spaced 1000ms apart. The CV value was accepted if the correlation coefficient between adjacent signals was more significant than 0.75. The estimated value of CV for each MVC level was averaged over channels. By using these techniques, the analysis method provides a comprehensive and accurate evaluation of muscle fatigue and recovery.

III. Experimental Results

A. Results from analysis of each MVC level

In this section, The analysis of the PSD, RMS, CV, and MMF of the sEMG signals recorded from the biceps brachii muscle at different levels of maximum voluntary contraction (MVC) was compared with previous studies. The findings' implications according to 10%MVC after-fatigue are also discussed for muscle fatigue assessment. The results interpretation will be constructed as follows.

The PSD in normalized units for each MVC level is shown in Fig. 3 (A). The PSD of 70%MVC fatigue is more concentrated in the lower frequency range, indicating a higher level of muscle activation. This is consistent with the report by [13]. On the other hand, the PSD of other MVC levels tends to shift to lower frequencies as the MVC level increases, suggesting a decrease in muscle activation.

Fig. 3 (B) compares the PSD of 10%MVC before-fatigue and 10%MVC after-fatigue. A significant difference between the two conditions was first found: the PSD of 10%MVC after-fatigue has a higher power spectrum in the higher frequency range. In comparison, the PSD of 10%MVC before-fatigue has a lower power spectrum at the same frequency range. This implies that 10%MVC after-fatigue signal has a higher muscle activation than 10%MVC before-fatigue. Note that this phenomenon has not been mentioned in any previous work and needs further analysis at higher MVC levels.

Fig. 3 (C) shows the general trend of RMS, which linearly increases to higher MVC levels. This coincides with previous studies such as [21], [23]. The RMS of 10%MVC after-fatigue and 10%MVC before-fatigue is almost unchanged. However, the RMS indicator needs to be combined with other indicators, such as MNF and CV, for a comprehensive understanding of muscle fatigue. In addition, 70%MVC fatigue has a higher RMS amplitude compared to other MVC levels because of higher muscle activation when the muscle is in the fatigue stage, which has been investigated in [17], [20].

As shown in Fig. 3 (D), the general trend of CV linearly decreases to higher MVC levels. This coincides with previous studies such as [9]. When the MNF of 10%MVC after-fatigue was compared with other MVC levels, we found that the CV of 10%MVC after-fatigue was the highest compared to other MVC levels. Note that the phenomenon has been overlooked

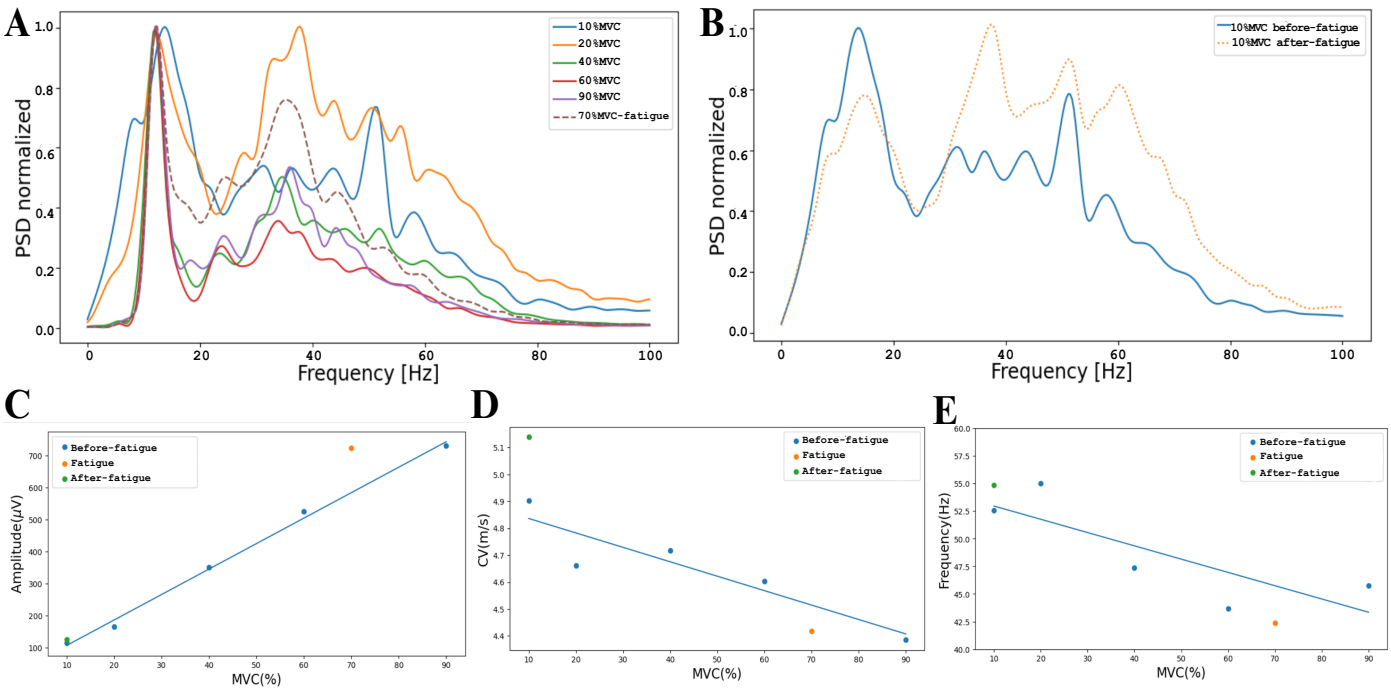

Fig. 3. (A) PSD normalized each MVC level. (B) PSD normalized of 10%MVC before-fatigue and after-fatigue. (C) RMS each MVC level. (D) CV each MVC level. (E) MNF each MVC level.

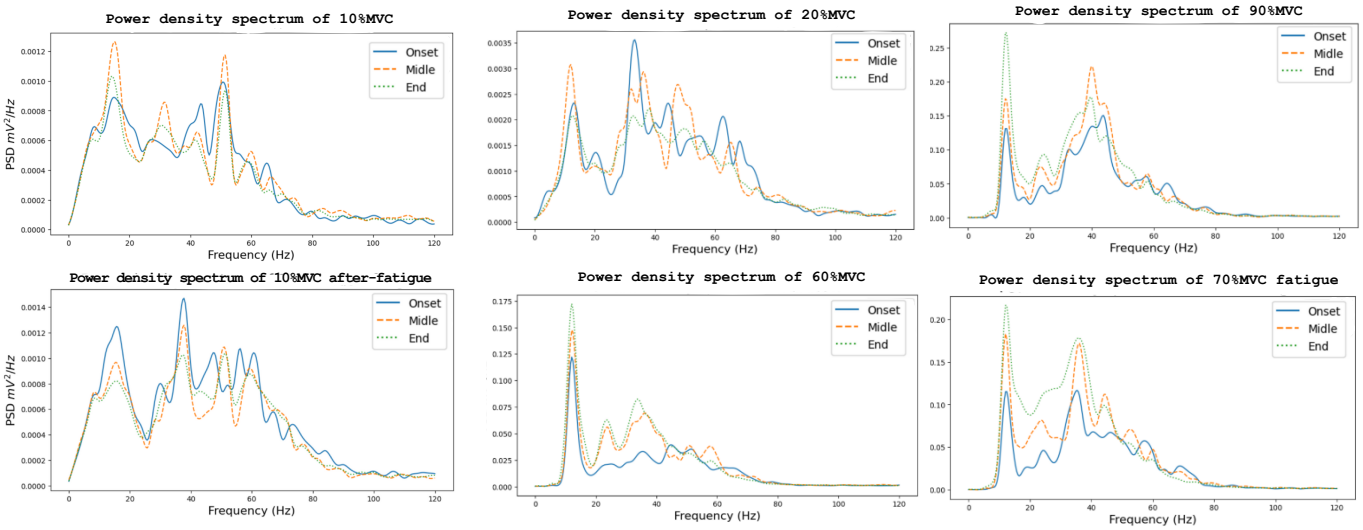

Fig. 4. Representation of the PSD shift during the contraction time.

in previous works. Therefore, we suggest that the robust increase in CV affects the PSD of 10%MVC after-fatigue, as mentioned above. In addition, 70%MVC fatigue has the lowest CV compared to other MVC because of the muscle fatigue stage. Finally, Fig. 3 (E) represents the general trend of MNF, which linearly increases to higher MVC levels. This also coincides with previous works such as [13], [16]. The MNF of 10%MVC after-fatigue was first observed, which has a higher frequency than 10%MVC before-fatigue; this phenomenon combines with indicators mentioned above that suggested a first evaluation of recovery conditions of muscle. In addition, 70%MVC has the lowest MNF compared to other MVC levels, which is the same as expected according to the above indicators.

In summary, novelty findings were found according to 10%MVC after-fatigue compared to other MVC levels. In addition, a shift of PSD to the right at 10%MVC after-fatigue was first found, compared to 10%MVC before-fatigue. This phenomenon comes with a robust increase in MNF and CV compared to other MVC levels. Based on the findings, We

TABLE I
PARAMETER'S SLOPE CHANGE OF EACH MVC LEVEL DURING CONTRACTION TIME

Parameters	MVC levels						
	10%MVC	20%MVC	40%MVC	60%MVC	90%MVC	70%MVC Fatigue	10%MVC (After-fatigue)
MNF	0.011	0.016	-0.321	-0.466	-1.019	-0.64	0.007
RMS	-0.357	-0.051	7.987	15.417	22.376	21.093	-0.004
CV	-0.001	-0.013	-0.019	-0.026	-0.045	-0.054	0.003

suggested a novelty evaluation of the after-fatigue conditions of muscle, where the shift to the right of PSD and increasing MNF denote higher muscle activation and a robust increase in CV denotes the reabsorption and distribution of ions such as H+ and K+ in the muscle membrane, leading to an increase in CV, as mentioned earlier. This further proved the more extended maintenance of contraction time at 10%MVC after-fatigue conditions.

B. Results from analysis contraction time

This section represents an analysis of the PSD indicator over time and evaluates the slope change of each parameter, such as MNF, RMS, and CV. Moreover, findings according to 10%MVC after-fatigue compared to other MVC levels and discuss their implications for muscle fatigue assessment. The results interpretation will be constructed as follows.

Fig. 4 represents the analysis of the PSD indicator over time. The compression trend of PSD was first generalized at various MVC levels and conditions over time, while [13] only exploited PSD on different MVC levels and some conditions. The PSD has a wide frequency, and the mean frequency is almost unchanged according to 10%MVC and 20%MVC before-fatigue. However, when MVC levels are increased, PSD tends to compress at a lower frequency apparent over time according to 60%MVC and 90%MVC. In addition, when the muscle is in the fatigue stage according to 70%MVC, the compression of PSD is not only at a lower frequency but also a robust increase in the power spectrum. Note that this finding has been overlooked in the previous studies.

In Table I, the slope change of all parameters such as MNF, RMS, and CV of each MVC level during contraction time were summarized. Firstly, we observed a general trend of MNF's slope at before-fatigue MVC levels. We first found that the higher the MVC levels, the more apparent MNF's slope decreases, which means the muscle tends to fatigue faster as higher force is required. In addition, MNF's slope of 70%MVC fatigue seems unaffected in fatigue conditions. MNF's slope of 10%MVC after-fatigue is nearly zero, which is almost unchanged over time and needs further analysis to understand fully.

In contrast to the general trend of MNF's slope, RMS' slope tends to increase as higher force is required according to before-fatigue conditions, as shown in Table I. In addition, RMS's slope of 70%MVC fatigue is nearly equal to 90%MVC, which means muscle needs more power to retain force than other MVC levels in fatigue conditions. In 10%MVC after-fatigue conditions, the slope nearly equals zero, requiring lower power to retain force. This phenomenon has been overlooked and needs further analysis. Finally, Table I shows the general CV's slope. CV's slope tends to decrease as higher force is required according to before-fatigue conditions. The CV's slope of 10%MVC after-fatigue was first found, which has a contrasted trend, slightly increasing compared to other MVC levels. Note that this phenomenon has not been reported in any previous works. We suggest that this phenomenon is related to the reabsorption and distribution of ions such as H+ and K+ in the muscle membrane. This leads to an increase in CV and the shift of PSD to the right, as we mentioned earlier.

In summary, a novelty analysis on the PSD indicators was proposed, which generalized the compression trend of PSD at various MVC levels and conditions over time and evaluated the slope change of each parameter, such as MNF, RMS, and CV. In addition, the findings were presented according to 10%MVC after-fatigue compared to other MVC levels.

IV. CONCLUSIONS

In this study, we proposed a method that analyzes muscle fatigue indicators at various MVC levels to fully evaluate muscle conditions according to the before-fatigue, fatigue, and after-fatigue conditions, and analysis of the contraction time of each MVC level is also analyzed with the same indicators to understand better how indicators change to time. The decline of CV, MNF, an increase of RMS, and a shift of power spectrum to lower frequency according to different MVC levels before and during muscle fatigue all provide results that we expect about the trend of muscle fatigue. Regarding the significant increase in muscle contraction maintenance time at 10%MVC level after muscle fatigue, we believe this increase in time is related to the reabsorption and redistribution of ions after muscle fatigue. As mentioned earlier, the change of CV has a solid relationship to the change of metabolism at the cell membrane. The CV also significantly impacts the amplitude and spectrum parameters, shown in the increased power spectrum density at higher frequencies and a slight increase in RMS and muscle force. However, this finding needs further investigation of the properties of the individual motor unit, such as firing rate, recruitment threshold, and synchronization.

***Abstract*—Minimizing training overhead in channel estimation is a crucial challenge in wireless communication systems. This paper presents an extension of the traditional blind algorithm, called "Mutually referenced equalizers" (MRE), specifically designed for MIMO systems. Additionally, we propose a novel semi-blind method, SB-MRE, which combines the benefits of pilot-based and MRE approaches to achieve enhanced performance while utilizing a reduced number of pilot symbols. Moreover, the SB-MRE algorithm helps to minimize complexity and training overhead and to remove the ambiguities inherent to blind processing. The simulation results demonstrated that SB-MRE outperforms other linear algorithms, i.e., MMSE, ZF, and MRE, in terms of training overhead symbols and complexity, thereby offering a promising solution to address the challenge of minimizing training overhead in channel estimation for wireless communication systems.**

***Index Terms*—Channel estimation, semi-blind, MRE, MIMO.**

I. Introduction

Multi-Input Multi-Output (MIMO) communication systems play a vital role in achieving reliable high data rate transmission while improving spectrum efficiency and channel capacity [1]. In order to mitigate channel distortions and separate source signals, MIMO systems employ an increased number of training sequences, usually referred to as pilots, which do not carry any useful data. However, this leads to a decrease in spectrum efficiency. In the 1990s, many studies proposed 'blind' (B) approach algorithms [2] to estimate the wireless channel without any pilot symbol. However, blind methods often have high complexity or require statistical information that is not ready for real-world systems. After all, pilot-based channel estimation techniques have dominated blind methods up to now.

In recent years, there has been a growing interest in the combination of pilot-based and blind methods, known as 'semi-blind' (SB) methods, which aim to reduce the number of pilots while maintaining stable performance [3]. In this work, we focus on the blind "Mutually referenced equalizers" (MRE) [4] algorithm, which is fast, global convergence, and flexible in implementation (i.e., Batch, LMS, RLS, ...). Since 1997, several studies have been proposed to develop the MRE algorithm. [5] firstly proposed recursive least-squares (RLS) implementation for the MRE method. In [6], Gesbert *et al.* introduced the MIMO version of the MRE method. In 2000, J. van der Veen *et al.* [7] proposed the combination of MRE with another blind algorithm, which is "Constant modulus" (CMA) for SIMO systems. [8] also used MRE method for SIMO models but reduced the complexity by computing only 2 instead of K equalizers as the original paper. Generally, most of the studies reviewed above and others tried to develop the MRE algorithm in the blind approach. As explained above, they often have one or more drawbacks, e.g., lack of support for MIMO; the need for intensive computational resources when the number of equalizers is large; and the requirement for several pieces of channel information, i.e., channel order and delay between receivers.

This motivates us to propose the SB-MRE method, a semi-blind approach for the MRE algorithm in MIMO systems. In detail, a few pilot symbols are used to improve the performance of the B-MRE component. To further enhance its effectiveness, we aim to reduce the overall cost of the SB-MRE method through two key improvements. Firstly, we decrease the complexity of the B-MRE component by reducing the number of equalizers to just 2. Secondly, we employ a straightforward adaptive algorithm that effectively minimizes the number of pilot symbols required in the SB-MRE method.

Our contribution in this paper is to propose an effective SB-MRE method for MIMO systems. The system model and B-MRE algorithm for MIMO systems are presented in section II. The novel SB-MRE algorithm is shown in section III. Two methods to reduce the cost of SB-MRE are presented in section IV. At last, we conduct numerical experiments to compare the performance of SB-MRE with other linear estimation methods.

$\mathbb{E}()$	Statistical expectation.
$\mathbf{0}$	Matrix of zeros.

II. MIMO-MRE

This section introduces the mathematical model of MIMO wireless communications used in this work. After that, the MRE algorithm for the MIMO model is briefly reviewed.

A. System model

The MIMO model, illustrated in Fig. 1, is composed of T transmitters and L receivers. Each channel between t-

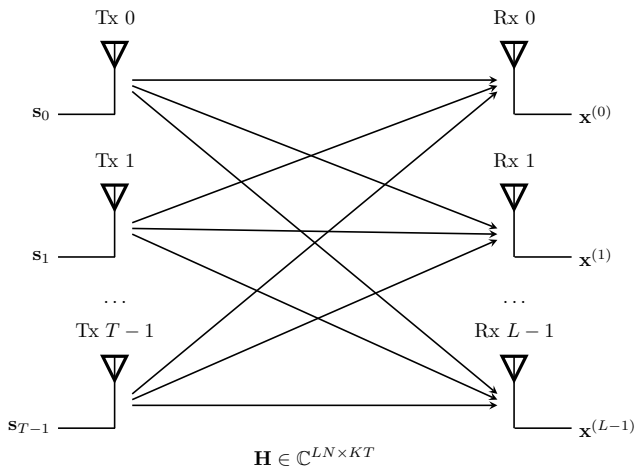

Fig. 1: Conventional MIMO communication model.

th transmitter and l-th receiver is formulated as a $M+1$ coefficients vector. At a time, N received symbols are simultaneously captured on each receiver. At time n, the following equation expresses the system model.

$$\mathbf{x}(n) = \sum_{t=0}^{T-1} \mathbf{H}_t \mathbf{s}_t(n) + \mathbf{w}_t, \tag{1}$$

where $\mathbf{s}_t(n) \in \mathbb{C}^{M+N\times 1}$ is the transmit symbols from the t-th transmitter. $\mathbf{H}_t$ is the channel convolution matrix between t-th transmitter and L receivers. $\mathbf{H}_t \in \mathbb{C}^{LN\times K}$ is assumed to be a full column rank ($K = M+N$) matrix. $\mathbf{x}(n) \in \mathbb{C}^{LN\times 1}$ denotes the observed signals and $\mathbf{w}_t \in \mathbb{C}^{LN\times 1}$ stands for additive white Gaussian noise matrix. Assume that channel and additive noise between each channel are i.i.d and have distributed $\mathcal{CN}(0, \sigma^2_{\mathbf{H}_t}\mathbf{I})$ and $\mathcal{CN}(0, \sigma^2\mathbf{I})$, respectively.

$$\mathbf{s}_t(n) = [s_t(n), s_t(n-1), \ldots, s_t(n-K+1)]^\top,$$

$$\mathbf{H}_t = \begin{pmatrix} h_{t,0}^{(0)} & \cdots & h_{t,M}^{(0)} & 0 & \cdots & 0 \\ \vdots & \cdots & \ddots & \cdots & \ddots & 0 \\ 0 & \cdots & 0 & h_{t,0}^{(0)} & \cdots & h_{t,M}^{(0)} \\ \vdots & \cdots & \vdots & \cdots & \cdots & \vdots \\ h_{t,0}^{(L-1)} & \cdots & h_{t,M}^{(L-1)} & 0 & \cdots & 0 \\ \vdots & \cdots & \ddots & \cdots & \ddots & 0 \\ 0 & \cdots & 0 & h_{t,0}^{(L-1)} & \cdots & h_{t,M}^{(L-1)} \end{pmatrix} \begin{matrix} \overset{K}{\longleftrightarrow} \\ \\ \\ \\ \\ \\ \\ \end{matrix} \updownarrow LN,$$

$$\mathbf{x}(n) = \big[x^{(0)}(n), \cdots, x^{(0)}(n-N+1), \cdots, x^{(L-1)}(n), \cdots, x^{(L-1)}(n-N+1)\big]^\top.$$

B. Brief review of MRE method

Generally, MRE uses an N-taps linear equalizer to filter each channel. Let $\mathbf{g}_{t,i} \in \mathbb{C}^{LN\times 1}$ be an i-delay equalizer and t-th transmitter. For each transmitter, the number of equalizers equals the maximum delay, which is K. For $i = 0, \ldots, K-1$, at time n, we have

$$\mathbf{g}_{t,i}^H * \mathbf{x}(n) = \sum_{l=0}^{L-1}\sum_{k=0}^{N-1} g_{t,i}^H(k) x^{(l)}(n-k) \approx \mathbf{s}_t(n-i), \tag{2}$$

$$\mathbf{g}_{t,i} = \big[g_{t,i}^{(0)}(0), \ldots, g_{t,i}^{(0)}(N-1), \ldots, g_{t,i}^{(L-1)}(0), \ldots, g_{t,i}^{(L-1)}(N-1)\big]^\top. \tag{3}$$

The equalizers matrix for t-th transmitter is $\mathbf{G}_t \in \mathbb{C}^{LN\times K}$ as follows:

$$\mathbf{G}_t = [\mathbf{g}_{t,0}, \ldots, \mathbf{g}_{t,K-1}]. \tag{4}$$

In the noise-free case, the transmitted symbols can be perfectly recovered with $\bar{\mathbf{G}}$ is any left inverse of $\mathbf{H}$ since

$$\begin{aligned} [\mathbf{G}_0, \ldots, \mathbf{G}_{T-1}]^H \mathbf{x}(n) &= [\mathbf{s}_0^\top(n), \ldots, \mathbf{s}_{T-1}^\top(n)]^\top, \\ \bar{\mathbf{G}}^H \mathbf{x}(n) &= \bar{\mathbf{s}}(n). \end{aligned} \tag{5}$$

In noisy case, to estimate $\bar{\mathbf{G}}$, the MRE method exploits the delay diversity from multi-channel, $\mathbf{g}_i^H \mathbf{x}(n) = \mathbf{g}_{i+1}^H \mathbf{x}(n+1)$, to determine the full set of channel inverses. Where $\mathbf{g}$ is the vector form of $\bar{\mathbf{G}}$ equalizers matrix as shown in Eq. (12). The unconstrained MRE cost function of $\bar{\mathbf{G}}$ is given by:

$$\mathcal{J}(\bar{\mathbf{G}}) = \mathbf{g}^H \mathcal{R} \mathbf{g}, \tag{6}$$

where $\mathcal{R} \in \mathbb{C}^{LNKT\times LNKT}$ is the matrix of $\mathbf{x}(n)$ and $\mathbf{x}(n+1)$ observed signals, which is given by:

$$\mathcal{R} \overset{\text{def}}{=} \mathbb{E}\left(\mathbf{U}^H \mathbf{U}\right), \tag{7}$$

with

$$\mathbf{U} = \big(\mathbf{I}_{T(K-1)}, \mathbf{0}\big) \otimes \mathbf{x}^H(n) - \big(\mathbf{0}, \mathbf{I}_{T(K-1)}\big) \otimes \mathbf{x}^H(n+1). \tag{8}$$

Under the quadratic constraint [4], the unique stable minimum of $\mathbf{g}$ is estimated by selecting the smallest eigenvector of $\mathcal{R}$.

III. Propose SB-MRE

In t-th transmitter, a block data $\mathbf{s}_t$ is considered to send, including N_p pilot symbols and $N_s - N_p$ data symbols.

$$\mathbf{s}_t(n) = [s_t(n), \ldots, s_t(n-N_p+1), s_t(n-N_p), \ldots, s_t(n-N_s+1)]^\top. \tag{9}$$

Pilot signals estimate the full set of channel inverse by the least-square method.

$$\hat{\mathbf{G}} = \arg \min_{\bar{\mathbf{G}} \in \mathbb{C}^{LN\times KT}} \sum_{i=N-1}^{N_p-1} \|\bar{\mathbf{s}}(n) - \bar{\mathbf{G}}^H \mathbf{x}(n)\|_F^2. \tag{10}$$

The combining of pilot-based and blind MRE is a constrained optimization that can readily solve by the Lagrange multiplier method [9]. The total cost function of SB-MRE will be

$$\mathcal{J}(\bar{\mathbf{G}}) = \sum_{i=N-1}^{N_p-1} \|\bar{\mathbf{s}}(n) - \bar{\mathbf{G}}^H \mathbf{x}(n)\|_F^2 + \lambda \mathbf{g}^H \mathcal{R} \mathbf{g}, \tag{11}$$

with λ is a weighting factor, $\mathcal{R}$ in the quadratic form of the blind MRE criterion as shown in Eq. (7), and $\mathbf{g}$ is the vector form of $\bar{\mathbf{G}}$.

$$\begin{aligned} \mathbf{g} = \mathrm{vec}(\bar{\mathbf{G}}) &= \left[\vec{\mathbf{G}}_0^\top, \vec{\mathbf{G}}_1^\top, \ldots, \vec{\mathbf{G}}_{K-1}^\top\right]^\top, \\ \vec{\mathbf{G}}_i &= \left[\ \mathbf{g}_{0,i}^\top, \mathbf{g}_{1,i}^\top, \ldots, \mathbf{g}_{T-1,i}^\top\ \right]^\top. \end{aligned} \tag{12}$$

Without loss of generality, the least-square expression of Eq. (11) is conjugate transposed and the sum operator is turned into matrix forms of $\widetilde{\mathbf{S}}$ and $\widetilde{\mathbf{X}}$. The cost function is expressed as follows:

$$\begin{aligned} \mathcal{J}(\bar{\mathbf{G}}) &= \sum_{i=N-1}^{N_p-1} \left\|\bar{\mathbf{s}}^H(n) - \mathbf{x}^H(n)\bar{\mathbf{G}}\right\|_F^2 + \lambda \mathbf{g}^H \mathcal{R} \mathbf{g} \\ &= \left\|\widetilde{\mathbf{S}}^H - \widetilde{\mathbf{X}}^H \bar{\mathbf{G}}\right\|_F^2 + \lambda \mathbf{g}^H \mathcal{R} \mathbf{g}. \end{aligned} \tag{13}$$

where $\widetilde{\mathbf{S}}, \widetilde{\mathbf{X}}$ are the matrices of shape $\mathbb{C}^{KT \times (N_p - N + 1)}$ and $\mathbb{C}^{LN \times (N_p - N + 1)}$, respectively.

$$\begin{aligned} \widetilde{\mathbf{S}} &= [\bar{\mathbf{s}}(N-1), \ldots, \bar{\mathbf{s}}\,(N_p - 1)], \\ \widetilde{\mathbf{X}} &= [\mathbf{x}(N-1), \ldots, \mathbf{x}\,(N_p - 1)]. \end{aligned}$$

The least-square expression is vectorized and thanks to the property for vector, i.e., $\mathrm{vec}(\mathbf{AXB}) = (\mathbf{B}^\top \otimes \mathbf{A}) * \mathrm{vec}(\mathbf{X})$. The SB-MRE cost function turned into

$$\begin{aligned} \mathcal{J}(g) &= \left\|\mathrm{vec}(\widetilde{\mathbf{S}}^H) - (\mathbf{I}_{KT} \otimes \widetilde{\mathbf{X}}^H)\,\mathrm{vec}(\bar{\mathbf{G}})\right\|_F^2 + \lambda \mathbf{g}^H \mathcal{R} \mathbf{g} \\ &= \|\bar{\mathbf{s}} - \mathbf{A}\mathbf{g}\|_F^2 + \lambda \mathbf{g}^H \mathcal{R} \mathbf{g} \\ &= \mathbf{g}^H \mathbf{A}^H \mathbf{A} \mathbf{g} + \|\bar{\mathbf{s}}\|_F^2 - 2\Re(\mathbf{g}^H \mathbf{A}^H \bar{\mathbf{s}}) + \lambda \mathbf{g}^H \mathcal{R} \mathbf{g}. \end{aligned} \tag{14}$$

In order to find minimum cost of Eq. (14), let derivative $\mathcal{J}(\mathbf{g})$ with respect to $\mathbf{g}$ as follows:

$$\begin{aligned} \frac{\partial \mathcal{J}}{\partial \mathbf{g}}(\mathbf{g}) &= 0, \\ \left(\mathbf{A}^H \mathbf{A} + \lambda \mathcal{R}\right) \mathbf{g} &= \mathbf{A}^H \bar{\mathbf{s}}. \end{aligned} \tag{15}$$

The final equalizers matrix in vector form of the proposed SB-MRE method is obtained through

$$\mathbf{g}_{SB} = \left(\mathbf{A}^H \mathbf{A} + \lambda \mathcal{R}\right)^{-1} \mathbf{A}^H \bar{\mathbf{s}}. \tag{16}$$

IV. Reduce the cost

In the ensuing, we aim to reduce the cost of the proposed SB-MRE algorithm by addressing two key factors, i.e., reducing the complexity of the B-MRE component and minimizing the training overhead.

A. Reducing the complexity of the B-MRE part

In the original study, the overall complexity of the blind MRE method is $\mathcal{O}(LNKT)$ [4]. Although all K equalizers are estimated for each transmitter, only one is ultimately utilized. However, this computational burden becomes unnecessary as N increases. Hence, in this section, we first considerably reduce the number of equalizers to 2, i.e., the 0-th and $(K-1)$-th equalizers. As a result, the overall complexity is reduced to $\mathcal{O}(LNT)$ and the equalizer matrix for the t-th transmitter can be represented as follows:

$$\mathbf{V}_t = [\mathbf{g}_{t,0},\ \mathbf{g}_{t,K-1}]. \tag{17}$$

Followed by the estimated signal source of t-th transmitter will be

$$\mathbf{V}_t^H \mathbf{x}(n) = [s_t(n), s_t(n-K+1)]^\top = \mathbf{s}_t(n). \tag{18}$$

Following that, we do not have to compute the full rank of $\mathcal{R}$ as the blind approach. Eq. (8) is modified to

$$\mathbf{U} = (\mathbf{I}_T, \mathbf{0}) \otimes \mathbf{x}^H(n) - (\mathbf{0}, \mathbf{I}_T) \otimes \mathbf{x}^H(n+K-1).$$

B. Reducing the training overhead for SB-MRE

In the least-square method, as indicated in Eq. (10), the performance of SB-MRE is primarily influenced by the number of pilot symbols (N_p). However, increasing the number of pilot symbols results in a decrease in spectral efficiency. To address this issue, we propose an adaptive algorithm that determines the minimum number of pilots required for the SB-MRE method.

First, we establish an assumption that after a few transmission sessions, the user equipment (UE) provides feedback to the base station (BTS) regarding the average symbol error rate (SER). This assumption is inspired by the feedback of the block error rate (BLER) in 5G standards [10]. Second, taking into account the channel state information (CSI), UE characteristics, and the specific service requirements, a target SER value ($\mathcal{T}$) is determined for a given transmission period. Subsequently, we define a straightforward loss function that measures the deviation from the target SER value as follows:

$$\mathcal{L}(\mathrm{SER}) = \log_{10}(\mathrm{SER}) - \log_{10}(\mathcal{T}). \tag{19}$$

The updating formula for the number of pilots N_p is

$$N_p = N_p + \delta * \mathcal{L}(\mathrm{SER}), \tag{20}$$

where δ is the learning rate.

Initially, the parameter δ is set to 1. If the feedback SER has not yet reached the target SER ($\mathcal{T}$), $\delta = \delta_1$. However, once the target SER is satisfied, the number of pilots is reduced to improve data efficiency, and during this phase, δ remains fixed at 1. The algorithm 1 shows our method to adapt the number of pilot symbols for SB-MRE. This approach can be seen as following a multiplicative-increase additive-decrease algorithm for adjusting the number of pilots. The reverse version, additive-increase multiplicative-decrease (AIMD), has been successfully adopted in networking, particularly the TCP congestion control algorithm [11]. Moreover, this scheme has been observed in nature, employed by biological systems, and even adapted for neural circuits [12].

V. Simulation Results

In this section, we present the experimental analysis of the proposed SB-MRE method using the simulation parameters outlined in Table I. The simulation results are based on an average of 500,000 runs. We begin by comparing the performance of the SB-MRE method against traditional channel estimation algorithms, namely Zero Forcing (ZF) and Minimum Mean Square Error (MMSE) [13], in terms of SER.

Fig. 2 shows that ZF and MMSE outperform the proposed SB-MRE at lower signal-to-noise ratio (SNR) values. This can be attributed to the fact that the influence of the B-MRE component is negligible at low SNR levels. However, as the SNR increases, the proposed SB-MRE gradually catches up to the SER of ZF and MMSE, eventually surpassing them at SNR = 10dB. It is important to note that the proposed SB-MRE algorithm only utilizes 32/256 symbols for pilots, whereas ZF and MMSE require complete knowledge of the CSI. Furthermore, even after reducing the cost of the B-MRE component, the modified SB-MRE (SB-MRE_rc) still outperforms both the original B-MRE and B-MRE_rc in terms of SER. This highlights the effectiveness of the proposed modifications in enhancing the performance of the SB-MRE algorithm.

TABLE I: Simulation parameters

Parameters	Specifications
MIMO	$T = 2, L = 4$
Modulation	QPSK
Channel order	$M = 3$
Windows size	$N = 10$
Sample size	$N_s = 256$
Pilots	$N_p = 32$
Number of blind equalizers	2
Weighting factor	$\lambda = 0.1$
Increase rate of N_p	$\delta_1 = 2$
Target SER	$\mathcal{T} = 10^{-4}, \mathcal{T}_\text{rc} = 10^{-2}$

After that, we simulate to verify the performance of the proposed SB-MRE in different numbers of pilots (N_p) and SNR values. As shown in Fig. 3, N_p and SNR are turned in the range of $[10 \;\; 64]$ pilot symbols and $[5, 10, 15]$ dB, respectively. Overall, SER curves of both SB-MRE and SB-MRE_rc exhibit

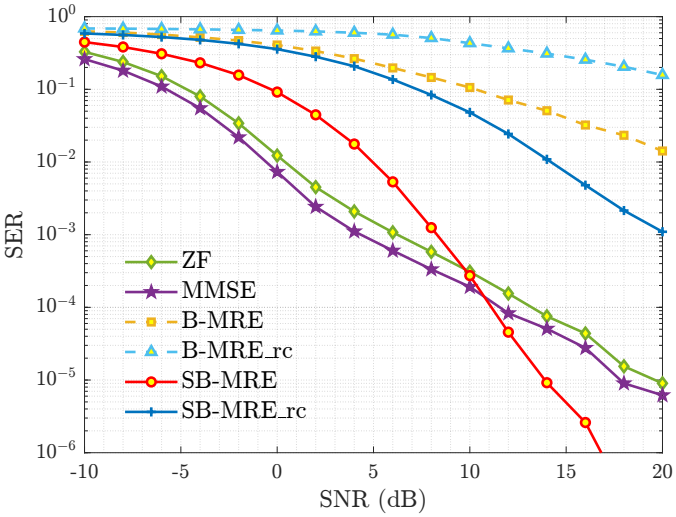

Fig. 2: Performance of proposed SB-MRE versus other channel estimation algorithms.

a gradual decrease as the number of pilot symbols (N_p) and SNR increase. This behavior represents a trade-off between spectrum efficiency and the accuracy of the channel estimation algorithm. At SNR = 15 dB, SB-MRE with $N_p > 40$ archives to SER $\approx 10^{-6}$. In the case of SB-MRE_rc, when the number of pilot symbols (N_p) is increased within the range of 10 to 40, there is a clear improvement in the SER curves. The SER decreases noticeably with an increasing number of pilots, indicating better performance. However, once N_p exceeds 40, the SER curves reach a stable state, and there is little to no further reduction in SER.

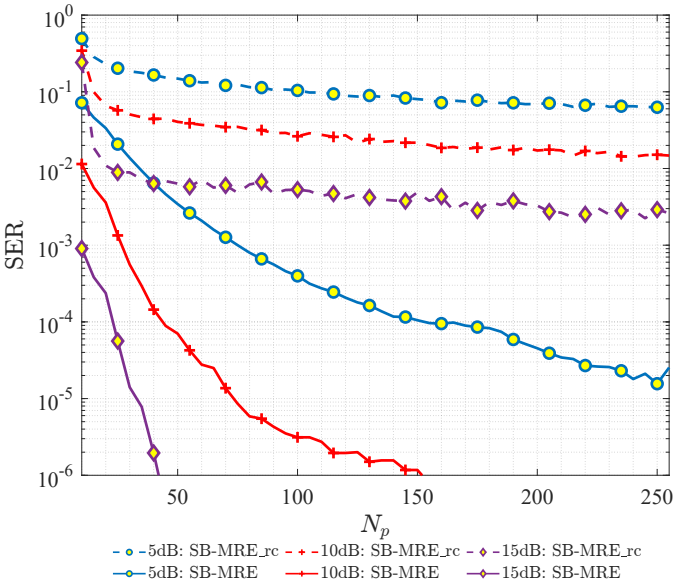

Fig. 3: Performance of proposed SB-MRE under various N_p and SNR values.

Fig. 4 demonstrates the impact of the weighting factor (λ) on the combination of pilot-based and B-MRE. The λ is varied

within the range of $[0.01 \;\; 0.2]$. For lower SNR levels (i.e., 5 dB and 10 dB), we observed a slight reduction in SER curves as λ values increased. However, at SNR $= 15$ dB, the performance of the B-MRE component became prominent, resulting in a significant decrease in the SER curves of SB-MRE. On the other hand, impacts of the weighting factor are negligible in the SB-MRE_rc version due to the small number of blind equalizers employed.

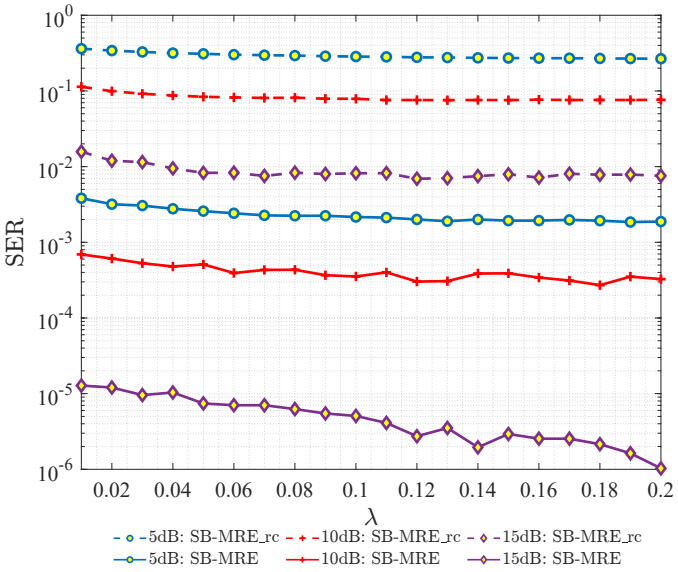

Fig. 4: Performance of proposed SB-MRE under various λ and SNR values.

Finally, the algorithm's performance to reduce the training overhead for SB-MRE is shown in Fig. 5. At SNR $= 12$ dB, the weighting factor (λ) is set at two levels, i.e., 0.1 and 0.15. According to simulation results in Fig. 3, the target SERs of SB-MRE, SB-MRE_rc are fixed at 10^{-4} and 10^{-2}, respectively. Overall, all scenarios' SER curves converge to their target SER after a certain number of iterations. However, the number of pilot symbols and iterations required for convergence vary significantly. For $\lambda = 0.1$, SB-MRE and SB-MRE_rc require 51 and 131 pilot symbols, along with 20 and 70 iterations, respectively. Conversely, for $\lambda = 0.15$, SB-MRE and SB-MRE_rc only need 13 and 15 pilot symbols, along with 1 and 5 iterations, respectively. These results highlight the effectiveness of the adaptive number of pilot symbols method for SB-MRE, with the λ value playing a crucial role in enhancing the performance of the SB-MRE algorithm, especially in high SNR scenarios.

VI. Conclusion

In this paper, we proposed a semi-blind version of the mutually referenced equalizers (MRE) algorithm designed for MIMO systems. Our algorithm uses a small number of pilot symbols to enhance the performance of the B-MRE. Furthermore, the SB-MRE algorithm also reduces the number of blind equalizers and pilot symbols required. Simulation results demonstrate that SB-MRE outperforms other B-MRE

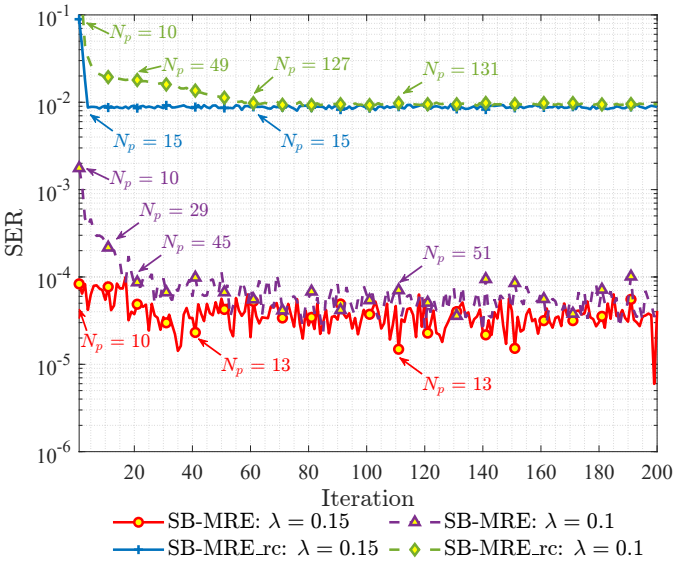

Fig. 5: Adapt the number of pilot symbols method for SB-MRE. The simulation parameters are $\mathcal{T} = 10^{-4}, \mathcal{T}_\text{rc} = 10^{-2}$, and SNR $= 12$ dB.

approaches and linear methods, particularly in high SNR scenarios. Additionally, we analyze the impact of the blind component and highlight the effectiveness of adapting the number of pilot symbols.

***Abstract*—Vision-based action recognition with the main aim to determine the action class from image sequence has emerged recently thanks to its potential applications. Numerous methods have been proposed for action recognition. However, majority of them mainly focus on isolated action recognition with the assumption that videos are segmented in different clips or shots, each of them contains an image sequence of one sole action. Different from isolated action recognition, continuous action recognition involves recognizing human actions from a continuous stream of input data without requiring pre-segmentation into discrete action instances. In this paper, we propose a method for continuous action recognition. The proposed method incorporates sliding window technique and a light weight action classification model named DDNet. We evaluate the proposed approach on several benchmark datasets. Experimental results show that the proposed method the accuracy of 0.95, 0.97 and 0.71 for IPN, UOW and InHARD datasets respectively on isolated action recognition task. On continuous recognition task, it has achieved a performance of 0.57, 0.76 and 0.33 on IPN, UOW and InHARD datasets.**

***Index Terms*—skeleton-based action recognition, continuous action recognition**

I. Introduction

The ability to recognize and understand human actions in real-time has important applications in various domains, including surveillance, human-robot interaction, and healthcare. In surveillance, distracting moments of drivers, and illegal house intrusion can be detected [1], [2]. In human-robot interaction, gesture and action recognition can enable robots to respond to human commands and intentions, facilitating natural and intuitive communication [3] while in healthcare domain, action recognition can be used to monitor and assist patients through physical rehabilitation [4].

Recent advances in deep learning have enabled significant progress in action recognition, leveraging approaches, including Convolutional Neural Networks (CNNs), Recurrent Neural Networks (RNNs), and graph-based models. These methods have demonstrated encouraging outcomes in the identification of diverse human actions within video sequences.

However, majority of existing work focus on isolated action recognition with the assumption that videos are segmented in different clips or shots, each of them contains an image sequence of one sole action. Different from isolated action recognition, continuous action recognition involves recognizing human actions from a continuous stream of input data without requiring pre-segmentation into discrete action instances.

Compared with isolated recognition, recognizing continuous actions poses a notably greater challenge as it has to tackle to variation of actions' length, unclear boundary between actions.

In this paper, we introduce a novel approach designed for continuous action recognition. The proposed method incorporates sliding window technique and a light weight action classification model named DDNet [5]. We assess the performance of our approach on various benchmark datasets and conduct a comparative analysis with state-of-the-art approaches, demonstrating its effectiveness and robustness in continuous action recognition tasks.

The rest of this paper is organized as follows: Section 2 provides a review of the related work in human action recognition. Section 3 describes the detailed information of the proposed approach. Section 4 shows our experiments on three different datasets of continuous action and gesture recognition and analyze in detail the experimental results. Conclusion and future works are illustrated in Section 5.

II. Related Works

In this section, we provide an overview of the related work on action recognition, highlighting the

979-8-3503-0067-3/23/$31.00 ©2023 IEEE

key contributions and limitations of existing methods. The study on video-based action recognition can be categorized into two fundamental groups: isolated and continuous action recognition.

Isolated action recognition takes split videos that contain only a single instance of action as inputs and predicts the action label. Many approaches have been proposed for isolated action recognition. Some authors used CNNs to capture local spatial patterns and temporal dynamics, thereby effectively modeling the complex motion characteristics of actions such as [6]. Due to the limitation of the single-frame image data input, some authors proposed to use 3D CNN to learn the temporal information for action recognition including different fusion approaches, spatio-temporal attention mechanisms, and dual-stream 3D-CNN [7], [8]. In addition, the method based on Long Short-Term Memory (LSTM) and CNN that have been proposed to recognize actions quickly and accurately [9]. Nayan *et al.* [10] proposed a combined RNN that uses CNN to extract features for a bidirectional LSTM (BD-LSTM). While CNN, 3D CNN and LSTM based methods mainly work on RGB sequence, different GCN models have been proved to be robust for skeleton-based action recognition.

Recently, some methods have been proposed to address continuous action recognition from RGB [11] or skeleton sequences [12]. These methods built a detector to determine whether an images sequence contains an action or not and a classifier that aims to identify the action class. Building a detector is tedious task as it requires to prepare a training set that consists of image sequences for non action/non gesture. Moreover, some methods could not guarantee real time processing. In [13], the authors propose a model consisting of a Spatio-Temporal GCN and the sliding window method for continuous action recognition from skeleton sequence. A sliding window of a predetermined size was applied to a continuous stream of skeleton data, and it was shifted as time advanced. This method allows to accelerate the recognition speed, however, GCN is still complex model that requires computational resources. In [12], a light model has been introduced for continuous hand gesture recognition. However, the model is designed for IPN dataset and could not work on other datasets.

III. Proposed method

A. Sliding Window

The proposed strategy, which is shown in Fig. 1, is divided into two stages: training and inference. In the training step, a light weight model based on DDNet is trained on isolated sequences of different actions. Then, in the inference step, sliding window technique is incorporated to recognize the dynamic gestures from continuous stream of video. The window size denoted ws needs to be set to a fixed number same as the input of DDNet. The number of frames in the sliding window is will be chosen for each dataset depending on the frame rate and the length of gestures. This window strides every 1 frame and returns the predicted label for the middle frame of the window.

B. DDNet

DDNet (a Double-Feature Double-Motion network) is a light weight model proposed for skeleton-based human action recognition [5]. Although being a light weight model, DDNet and its variants provides state-of-the-art results on different datasets [2].

In Fig. 2, we conducted a performance comparison of recognition models using the MSRAction dataset [14] in term of both FLOPs and accuracy. We can observe that DD-Net results a good recognition rate while requires less computational time compared to GCN model.

DDNet consists of three branches that aims at extracting both spatial and temporal features from skeleton sequence. There branches are Slow motion, Fast motion and Joint Collection Distances (JCD). Each branch contains three CNN layers. Slow and Fast motions are designed to capture the movement of the actions while JCD is dedicated to spatial information.

Denote S^{t+1} and S^{t+2} are the skeleton of one frame and two frames behind the skeleton at frame t S^t, F^t_{slow} and F^t_{fast} that are denoted as the Slow Motion the Fast Motion and are computed as follows:

$$F^t_{slow} = S^{t+1} - S^t, t \in 1, 2, 3, ..., T-1; \quad (1)$$

$$F^t_{fast} = S^{t+2} - S^t, t \in 1, 3, ..., T-2; \quad (2)$$

Concerning JCD, it is extracted from a Euclidean distance matrix. Each element of the matrix represents the Euclidean distance between a pair of joints in the same frame. At frame t, JCD feature can be computed by using the following equation.

$$JCD^t = \begin{bmatrix} \left\|\overrightarrow{\mathbf{j_2^t j_1^t}}\right\| & & & \\ \vdots & \ddots & & \\ \vdots & \cdots & \ddots & \\ \left\|\overrightarrow{\mathbf{j_N^t j_1^t}}\right\| & \cdots & \cdots & \left\|\overrightarrow{\mathbf{j_N^t j_{N-1}^t}}\right\| \end{bmatrix} \quad (3)$$

where $\left\|\overrightarrow{\mathbf{j_k^t j_l^t}}\right\| (k \neq l)$ is the Euclidean distance between two joints $\mathbf{j_k^t}$ and $\mathbf{j_l^t}$ of the skeleton S^t.

IV. Experimental Results

A. Datasets

We conducted our experiments on the following continuous gesture datasets, which is widely used for evaluating continuous action recognition algorithms. **IPN** [11]: This dataset includes over 4,000 gesture samples and 800,000 RGB frames from 50 different individuals. 13 different static and dynamic gestures were created to focus on interactions with touchless screens. The main characteristic of the dataset is that the continuous gestures are performed without tran-

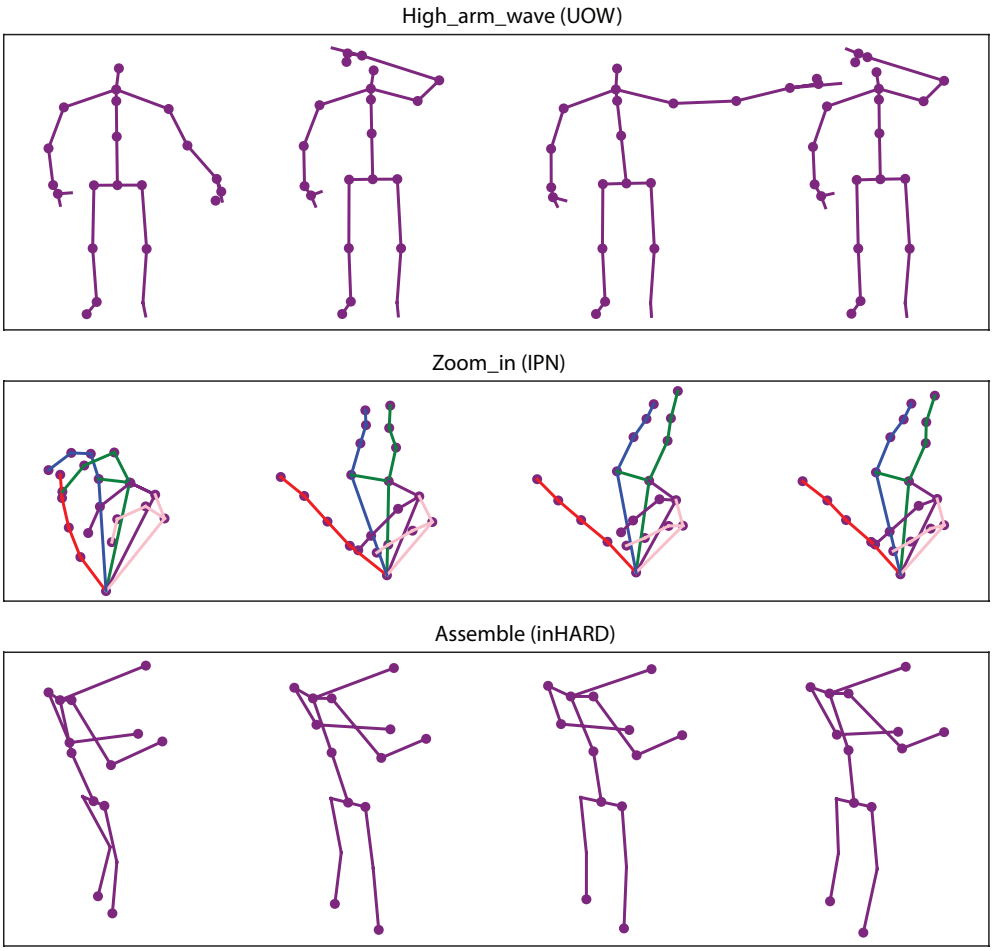

Fig. 4: Example of skeleton sequences of UOW, IPN and InHARD datasets

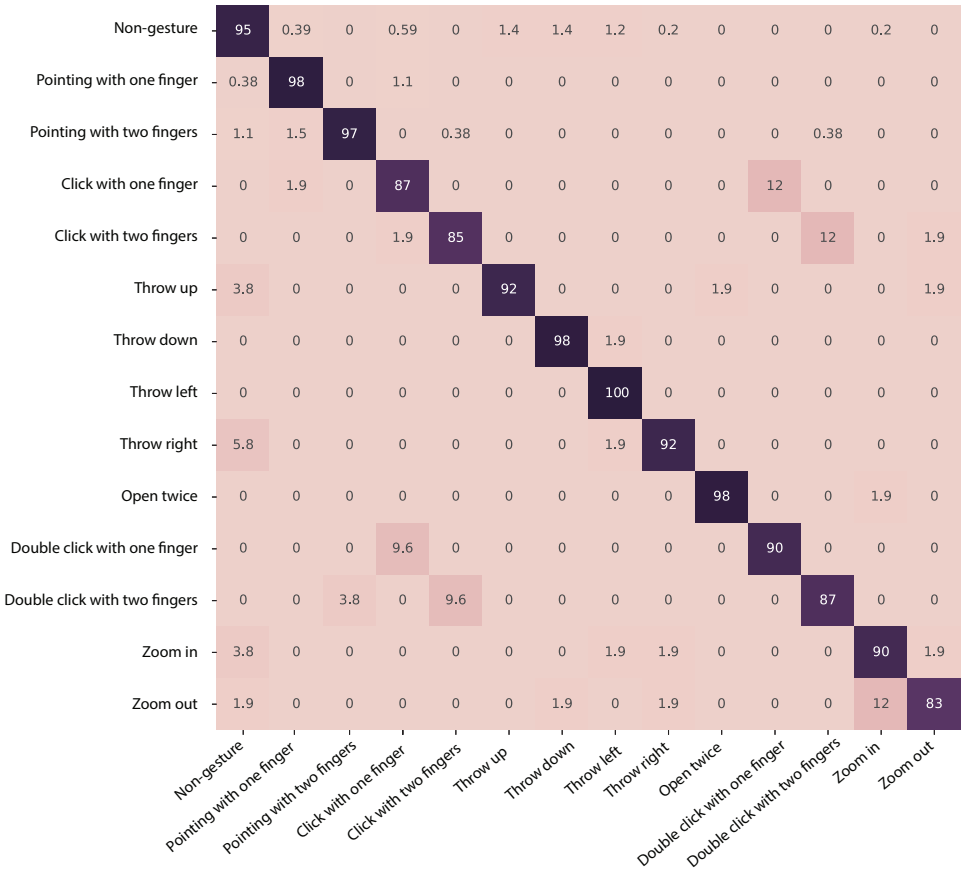

Fig. 5: Isolated action classification on IPN dataset

sition states and non-gesture actions are performed by subjects using natural hand movements. Gestures were captured in about 30 different settings with various backgrounds and lighting conditions to introduce real-world variation. Since the skeleton information is not available on this dataset, we estimate hand joint landmarks from provided video by using MediaPipe [15], an open-source cross-platform framework developed by Google that provides a pipeline for building real-time applications.

UOW: [16] The UOW Online Action3D Dataset contains action sequences of 20 actions. These actions are defined in MSR Action3D Dataset. The dataset were captured using Microsoft Kinect V.2 and comprises videos of 20 subjects. Each subject performed one action from 3 to 5 times before performing 20 actions continuously in a random order. The dataset has two subsets: a subset of continuous action sequences can be utilized for evaluation of continuous action recognition methods while the subset of repeated action sequences will be used for isolated action recognition or training purposes.

InHARD (Industrial Human Action Recognition Dataset): [17] has recently released for human-COBOT interaction context. This dataset contains over 4800 action samples that perform 13 different industrial action classes named meta-action. The authors use a motion sensor system to capture the human skeleton at 120 Hz. Figure 4 shows example of skeleton sequence of these datasets. It is worth to note that the number of joints for IPN, UOW and InHARD datasets are 21, 25 and 17 respectively.

B. Implementation details and evaluation metrics

The size of the window depends on the frame rate and gesture length of each dataset. We set the window size of UOW and IPN is 60 and of inHARD is 240. All experiments were conducted on a PC with an Intel Core i7 8750H processor.

To assess the performance action recognition system, we employ the video-wise accuracy for isolated recognition and frame-wise accuracy for continuous recognition. Frame-wise accuracy compares the predicted label vs the ground-truth label at frame level.

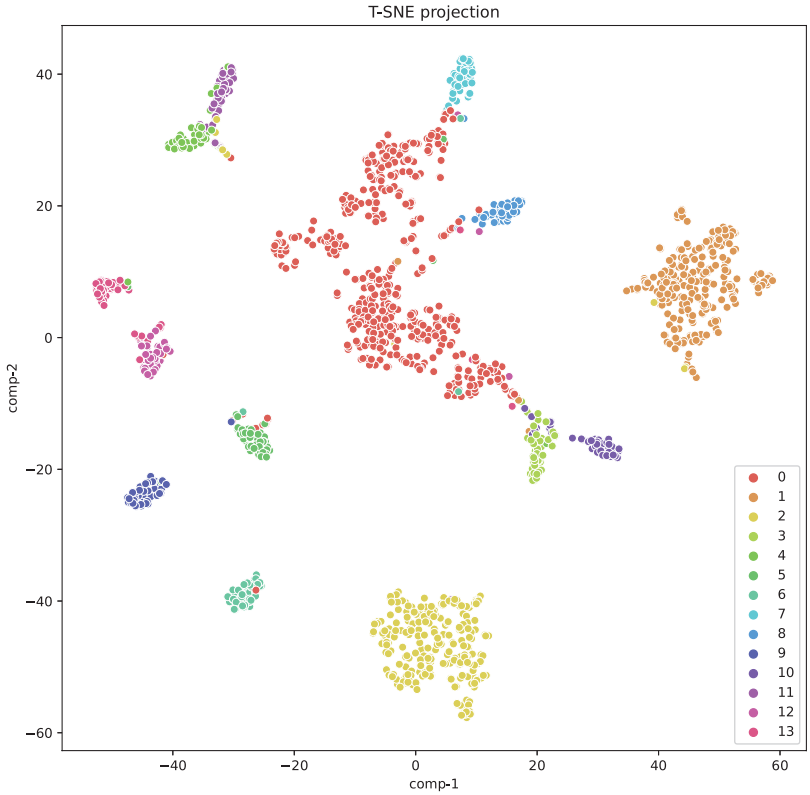

Fig. 6: Feature space learned from DDNet model for IPN dataset

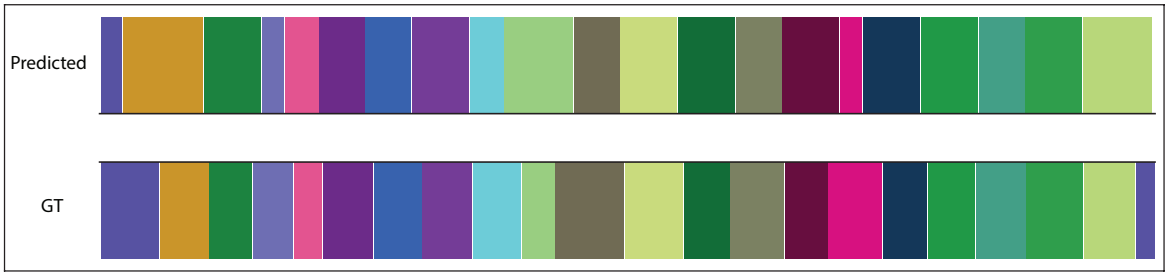

Fig. 7: Illustration of continuous action recognition on a sequence of UOW dataset. The first line represents the results of the proposed method while the second line shows the corresponding ground-truth. Each action label is represented by an identical color.

C. *Results*

As the proposed method consists of two main components: the sliding window technique and an action classifier based on DDNet. We evaluate first the performance of action classifier. Table I shows the accuracies obtained for three benchmark datasets. The accuracies obtained for IPN, UOW and InHARD are 0.95, 0.97 and 0.71 respectively. We can observe that the model based on DDNet could distinguish different actions with high accuracy. Among three datasets, the performance obtained for InHARD is lowest. The main reason is that in InHARD contains 74 actions belonging to 13 meta-actions, each type of meta-action has many variations of actions, therefore, it is hard to achieve the high accuracy in classification task. For IPN dataset, even with skeleton extracted by off the shelf method [15] and the high inter-similarity between action classes, the method still could recognize very well the actions. Figure 3 illustrates the RGB sequence and its corresponding skeleton sequence for ”Throw down” action of IPN dataset. Figure 5 shows the confusion matrix obtained for IPN while Fig. 6 shows the feature distribution of 13 actions in IPN dataset using t-SNE method. We can observe that the ”Click” and ”Double click” actions get a lot of confusions between 1 and 2

fingers. This can be explained by the similarity in the movement. In some cases, 1 of 2 fingers can be obscured leading Mediapipe only estimating 1 finger. Table II compares the performance of the proposed method with CNN and GCN based methods in [13] on three benchmark datasets: IPN, UOW, and InHARD. The two first row represents results of the SW-CNN, the SW-GCN method [13], which has achieved a performance of 0.68, 0.75 in term of frame-wise accuracy on the UOW dataset. The last row represents the proposed method, which has achieved a performance of 0.57 on the IPN dataset, 0.76 on the UOW dataset, and 0.33 on the InHARD dataset.

Figure 7 illustrates recognition for a continuous sequence in UOW dataset. The first line represents the proposal's results whereas the second line shows the corresponding ground-truth. Each action label is represented by an identical color. From this figure, we can observe that the capability of the proposed method to accurately localize and recognize different action instances from input sequence. However, for some actions such as the two first segments present the transition from non-gesture to "pick up & throw" gesture. Because the sliding window returns the label of the middle frame, in this case, skeletons in the window contains both non-gesture frame and the starting frame of "pickup" gesture. Therefore, it is recognize as pick up gesture.

V. Conclusion and Future Works

In this paper, a method for continuous action recognition from a skeleton sequence has been proposed. The proposed method incorporates sliding window technique and a light weight action classification model. Based on our experiments conducted on three benchmark datasets, the proposed method achieved remarkable accuracy scores of 0.95, 0.97, and 0.71 for the IPN, UOW, and InHARD datasets, respectively. These results pertain specifically to the isolated action recognition task. On continuous recognition task, it has achieved a performance of 0.57, 0.76 and 0.33 on IPN, UOW and InHARD datasets. Although the proposed method obtains promising results for isolated recognition task, there is still room for improvement for continuous recognition especially when working with challenging dataset such as InHARD.

***Abstract*—In this paper, we propose a deep learning-based signal detector called TransD3D-IM, which employs the Transformer framework for signal detection in the Dual-mode index modulation-aided three-dimensional (3D) orthogonal frequency division multiplexing (DM-IM-3D-OFDM) system. In this system, the data bits are conveyed using dual-mode 3D constellation symbols and active subcarrier indices. As a result, this method exhibits significantly higher transmission reliability than current IM-based models with traditional maximum likelihood (ML) detection. Nevertheless, the ML detector suffers from high computational complexity, particularly when the parameters of the system are large. Even the complexity of the Log-Likelihood Ratio algorithm, known as a low-complexity detector for signal detection in the DM-IM-3D-OFDM system, is also not impressive enough. To overcome this limitation, our proposal applies a deep neural network at the receiver, utilizing the Transformer framework for signal detection of DM-IM-3D-OFDM system in Rayleigh fading channel. Simulation results demonstrate that our detector attains to approach performance compared to the model-based receiver. Furthermore, TransD3D-IM exhibits more robustness than the existing deep learning-based detector while considerably reducing runtime complexity in comparison with the benchmarks.**

***Index Terms*—TransD3D-IM, deep learning, BER, DNN, dual-mode, index modulation, DM-IM-3D-OFDM.**

I. Introduction

Combining orthogonal frequency division multiplexing (OFDM) with index modulation (IM) methods, namely OFDM-IM [1], [2] has gained dominant attention as a potential approach to substitute the traditional OFDM technique. In OFDM-IM, a subset of subcarriers is activated to transmit data through both subcarriers and their corresponding indices. As a result, the OFDM-IM approach outperforms for both reliability and energy efficient compared to traditional methods thanks to using indices of active subcarriers to convey data. Additionally, adjusting the number of activated subcarriers promises to offer an flexible trade-off between the error performance and spectral efficiency (SE).

In recent years, various advanced OFDM-based systems have been introduced [3]–[6], aiming at enhancing either the error performance or SE. Additionally, the dual-mode OFDM (DM-OFDM) [7] and three-dimensional OFDM (3D-OFDM) [8] are also known as the efficiency approach in reducing the bit error rate (BER) of the traditional OFDM. In particular, DM-OFDM utilizes multiple constellations to convey data using subcarriers that are not activated. In comparison with OFDM-IM, DM-OFDM has shown superior in higher achievable SE. A generalized variant of DM-OFDM which greatly improves the SE of the traditional version in [9]. In the process of 3D-OFDM, data bits are converted to the 3D constellation symbols, and the obtained set of symbols is divided into subcarriers, which are employed the 2D inverse fast Fourier transform for modulation. By employing OFDM with a 3D mapper instead of a 2D one, the minimum Euclidean distance among different constellations notably increases. These enhancement results in error performance thereby reduce the likelihood of transmission errors. In [10] and [11], authors presented the analysis for symbol error probability (SEP) and the solution to decrease the peak-to-average power ratio of 3D-OFDM. Nevertheless, its SE is only one-third compared to the classical OFDM when considering the constellation order [12]. Motivated by the IM idea, a novel scheme combined by 3D-OFDM [8] and DM-OFDM [7], namely dual-mode IM-aided 3D-OFDM (DM-IM-3D-OFDM), was introduced in [13] to enhance SE of 3D-OFDM. Within this model, data bits are conveyed via indices of activated subcarriers and the 3D mapper constellations based on the floor of the Poincare sphere [14]. In particular, subcarriers are divided into subblocks, and subcarriers in each subblock are split into two groups, and then mapped by dual-mode 3D constellations. In comparison with 3D-OFDM, DM-IM-3D-OFDM demonstrates superior to transmission reliability at large SNRs when employing the maximum likelihood (ML) detection under the fading channels. However, its computational complexity is high, especially as parameters of model are large. Even the complexity of the Log-Likelihood Ratio (LLR) algorithm, known as a low-complexity detector for signal detection in the DM-IM-3D-OFDM system, is also not impressive enough. Consequently, we propose a new detector to solve this fundamental issue.

Recently, Deep Learning (DL) [15] has been broadly applied to the physical layer of wireless communication systems [16]–[21]. Furthermore, the DL-based detector successfully employs the Transformer framework [22] for signal detection in the OFDM-IM system, especially when the model parameters are large [23]. To the best of our knowledge, the application of DL Transformer architecture to the DM-IM-3D-OFDM has been overlooked in the literature. In this contribution, our proposal focuses on a novel Transformer-based DL detector called TransD3D-IM for signal detection of the DM-IM-3D-OFDM

979-8-3503-0067-3/23/$31.00 ©2023 IEEE

system. In particular, we build a new deep neural network (DNN) model of TransD3D-IM based on the Transformer framework. In our proposal, the Transformer block plays a crucial role as it calculates global dependencies and features with the 3D signal, which allows to obtain BER performance improvement. Aiming of minimizing BER, TransD3D-IM is trained offline by employing the simulation dataset. After that, it plays the role of an online detector to quickly estimate the conveyed bits. Our simulation results pointed out that TransD3D-IM can achieve an approach BER performance and much lower runtime complexity than the previous detectors.

The remaining parts of the paper are organized as follows. Section II describes the system model of DM-IM-3D-OFDM and conventional ML and LLR detectors. Section III presents the structure and model training of our proposed TransD3D-IM detector. Subsequently, Section IV shows the results achieved by our transformer-based detector and compares it with conventional detectors. Lastly, Section V is conclusion.

II. SYSTEM MODEL

The diagram in Fig. 1 illustrates the structure of a DM-IM-3D-OFDM simplified system, where data are conveyed by mapping 3D constellations and subcarrier indices. It is assumed that the message consisting of b bits are split into m subblocks of n subcarriers and p bits, i.e. $m = b/p = N/n$, where N is the number of subcarriers per subblock. Herein, the p bits are split into two components based on the dual 3D constellation-IM scheme. The first component, referred to as the index bit, consists of p_1 bits. The index bit serves as a selector to divide the subcarrier indices into two subsets. The second component, known as the information bits, consists of p_2 bits and is mapped to two distinct constellations: type A and type B, denoted by $\mathcal{S}_A$ and $\mathcal{S}_B$, respectively. Specifically, symbol sets of $\mathcal{S}_A$ and $\mathcal{S}_B$ are represented by $\mathcal{M}_A$ and $\mathcal{M}_B$ that associated with the size of s_A and s_B, respectively, note that $\mathcal{M}_A \cap \mathcal{M}_B = \varnothing$. In the frequency domain, each element of $\mathcal{M}_A$ can be expressed by $\mathcal{M}_A^j = (x, y, z)^T$, i.e., j-th symbol from the symbol set $\mathcal{M}_A$ where $1 \leq j \leq s_A$ and x, y, z are coefficients of base vectors in $x-$, $y-$, and $z-$axis. In addition, $(.)^T$ presents the transposition. Value of k stands for the number of subcarriers modulated by $\mathcal{S}_A$, thus the number of subcarriers mapped to $\mathcal{S}_B$ is $n - k$. Accordingly, we can determine the value of p as follows.

$$p = p_1 + p_2 = \lfloor \log_2 C_n^k \rfloor + \log_2((s_A)^k) + \log_2((s_B)^{n-k}), \quad (1)$$

where C_n^k is the binomial coefficient and $\lfloor . \rfloor$ denotes the integer floor operator. Additionally, the index selectors of the two 3D mapper constellations have an interdependent relationship. Specifically, once the index selector of $\mathcal{S}_A$ is determined, the corresponding index selector of $\mathcal{S}_B$ is also known. Therefore, it is sufficient to define the index selector of $\mathcal{S}_A$ in order to describe the principle of the index selector. For instance, it can be selected that $n = 4$, $k = 2$, and $s_A = s_B = 2$ for each OFDM subblock. The IM procedure is presented in Table I.

TABLE I
THE LOOK-UP TABLE FOR DM-IM-3D-OFDM SYSTEM

IM Bits	Indices for $\mathcal{S}_A$	Subblocks
$[0, 0]$	$[1, 2]$	$[\mathcal{S}_A^1, \mathcal{S}_A^2, \mathcal{S}_B^1, \mathcal{S}_B^2]$
$[0, 1]$	$[2, 3]$	$[\mathcal{S}_B^1, \mathcal{S}_A^1, \mathcal{S}_A^2, \mathcal{S}_B^2]$
$[1, 0]$	$[3, 4]$	$[\mathcal{S}_B^1, \mathcal{S}_B^2, \mathcal{S}_A^1, \mathcal{S}_A^2]$
$[1, 1]$	$[1, 4]$	$[\mathcal{S}_A^1, \mathcal{S}_B^1, \mathcal{S}_B^2, \mathcal{S}_A^2]$

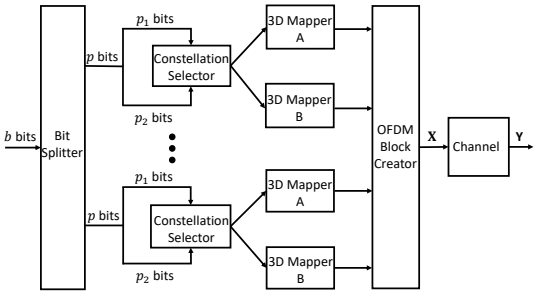

Fig. 1. Block diagram of the DM-IM-3D-OFDM system.

In the frequency domain, the transmitted signal $\mathbf{X} \in \mathbb{C}^{3\times n}$ in a block is constructed by $\mathbf{X} = [\mathbf{X}(1), \mathbf{X}(2), \ldots, \mathbf{X}(n)]$, where $\mathbf{X}(i) \in \{\mathcal{S}_A, \mathcal{S}_B\}$ and $1 \leq i \leq n$. Particularly, the output of two mappers can be represented by $\mathcal{S}_A = [\mathcal{S}_A^1, \ldots, \mathcal{S}_A^k]$, where $\mathcal{S}_A^i = \mathcal{M}_A^j$ $(1 \leq i \leq n, 1 \leq j \leq s_A)$ and $\mathcal{S}_B = [\mathcal{S}_B^1, \ldots, \mathcal{S}_B^{n-k}]$, where $\mathcal{S}_B^i = \mathcal{M}_B^j$ $(1 \leq i \leq n-k, 1 \leq j \leq s_B)$. Noting that the process of designing 3D constellations to built-up the signal matrix $\mathbf{X}$ is presented in detail in [13], the index selector may be obtained by the look-up table as shown in Table I.

At the receiver, the obtained signal matrix $\mathbf{Y} \in \mathbb{C}^{3\times n}$ in the frequency domain can be represented as follows.

$$\mathbf{Y} = \mathbf{H}\mathbf{X} + \mathbf{G}, \quad (2)$$

where $\mathbf{H} = [\mathbf{H}_1; \mathbf{H}_2; \mathbf{H}_3]^T \in \mathbb{C}^{3\times n}, \mathbf{H}_i \in \mathbb{C}^{1\times n}$ and $\mathbf{G} = [\mathbf{G}_1; \mathbf{G}_2; \mathbf{G}_3]^T \in \mathbb{C}^{3\times n}, \mathbf{G}_i \in \mathbb{C}^{1\times n}$ $(1 \leq i \leq 3)$, represent the fading channel coefficients and the additive white Gaussian noise (AWGN), respectively. Each entry of $\mathbf{H}$ and $\mathbf{G}$ are identically and independently distributed as a complex-valued random variable, with $\mathbf{H}_i(\alpha) \sim \mathcal{CN}(0, 1)$ and $\mathbf{G}_i(\alpha) \sim \mathcal{CN}(0, N_0)$ $(1 \leq \alpha \leq n)$, respectively, where N_0 is the noise variance.

At the received side, the ML detector is employed and the estimated signal denoted by $\hat{\mathbf{X}}$ is calculated by

$$\hat{\mathbf{X}} = \arg \min_{\mathbf{X}\in\delta} \| \mathbf{Y} - \mathbf{H}\mathbf{X} \|^2, \quad (3)$$

where $\| . \|^2$ is the squared Euclidean norm and δ stands for the set of all possible candidate delivery vectors modulated with $\mathcal{S}_A$ and $\mathcal{S}_B$. While ML can yield good performance, it becomes impractical as the values of p_1 and k increase due to its exponential growth. Moreover, $\hat{\mathbf{X}}$ can be recovered through the LLR detector by considering that the subcarriers are modulated by either $\mathcal{S}_A$ or $\mathcal{S}_B$, the LLR algorithm provides the ratio of the posterior probabilities, which can be expressed by

$$\delta_i = \ln\left(\frac{\sum_{j=1}^{s_A} P(\mathbf{X}(i)=\mathcal{M}_A^j) \mid \mathbf{Y}(i)}{\sum_{j=1}^{s_B} P(\mathbf{X}(i)=\mathcal{M}_B^j) \mid \mathbf{Y}(i)}\right), \quad (4)$$

where $1 \le i \le n$, $\mathcal{M}_A^j \in \mathcal{M}_A$ and $\mathcal{M}_B^j \in \mathcal{M}_B$. As observed in (4), the value of δ_i determines whether the i-th subcarrier is modulated by $\mathcal{S}_A$ or $\mathcal{S}_B$. For instance, if δ_i is larger, it is more probably that the i-th subcarrier is modulated by $\mathcal{S}_A$, whereas if δ_i is smaller, it is more probably to be modulated by $\mathcal{S}_B$. The LLR detector provides near-optimal performance by making hard decisions, while its complexity is significantly lower than the ML detector.

III. Proposal of TransD3D-IM Detector

This section first describes the operation of the TransD3D-IM detector and provides a comprehensive overview of its structure. Lastly, the offline training procedure is presented for our proposed detector.

A. Outline of TransD3D-IM

Firstly, we present a description of the TransD3D-IM detection process. As depicted in Fig. 2, the received signal and the channel $\mathbf{H}$ are fed to a pre-processing module. The resulting matrix from this module passed through a linear fully connected (FC) layer to produce a matrix with a higher row dimension. Following the linear FC layer, a Transformer block is employed, comprising a multi-head attention (MHA) layer, a multi-layer perceptron (MLP), and layer normalization operations. By performing a sequence of computations and projections within aforementioned DNN blocks, the TransD3D-IM input is transformed into the matrix of identical dimensions, which effectively represents the extracted dependencies and features from the input data. The neural networks have the output data, represented as intermediate matrix $\mathbf{O}$, providing soft probabilities for various symbols before next manipulations. Based on the intermediate matrix $\mathbf{O}$, the indices set of two mapper constellations are selected by the last column of this matrix. Then, the symbols corresponding to their mapped 3D constellation are recovered based on both matrix $\mathbf{O}$ and the previously recovered indices. By combining the process index and symbol parts, the transmitted data could be accurately recovered.

B. Structure of TransD3D-IM

Next, we present the core details of each DNN module in the proposed TransD3D-IM detector.

Pre-Processing: Pre-Processing module takes the received signal $\mathbf{Y}$ and the channel matrix $\mathbf{H}$ as inputs and implements zero-forcing (ZF) to build-up an equalized signal vector $\bar{\mathbf{Y}}$ at the receiver, which is presented by

$$\bar{\mathbf{Y}} = \mathbf{Y}\mathbf{H}^{-1}. \quad (5)$$

The received signal's energy matrix represented as $\mathbf{Y}_E$ is computed to realize various subcarriers clearly. We then concatenate $\bar{\mathbf{Y}}_R$, $\bar{\mathbf{Y}}_I$ and $\mathbf{Y}_E$ in parallel and get a matrix $\mathbf{I} = [\bar{\mathbf{Y}}_R, \bar{\mathbf{Y}}_I, \mathbf{Y}_E]$ as the input data of the Linear FC layer, where $\bar{\mathbf{Y}}_R$ and $\bar{\mathbf{Y}}_I$ represent the real and imaginary components of the vector $\bar{\mathbf{Y}}$, respectively.

Linear Fc layer: Next, the matrix $\mathbf{I}$ enters a linear FC layer, where employing the rectifier linear unit (ReLU), $f_{\text{ReLU}}(x) = \max(0, x)$ as the activation function. This module is implemented to get a matrix $\mathbf{C}$ with a higher row dimension. The resulting matrix $\mathbf{C}$ can be expressed as follows.

$$\mathbf{C} = f_{\text{ReLU}}(\mathbf{I} \times \mathbf{W}_{\text{C}} + \mathbf{b}_{\text{C}}), \quad (6)$$

where $\mathbf{W}_{\text{C}}$ and $\mathbf{b}_{\text{C}}$ represent weights and biases to be learned, respectively.

Transformer Block: Transformer Block plays a crucial role in our proposed detector. This block is employed to transform vector $\mathbf{C}$ into another matrix, effectively representing the extracted dependencies and features of the transmitted data bits. The details descriptions for every module are described along the following lines.

• *Multi-Head Attention Layer (MHAL):* MHA is derived by the single-head self-attention mechanism, which involves the calculation for queries of $\mathbf{Q}$, keys of $\mathbf{K}$, values of $\mathbf{V}$ [22] and the matrix $\mathbf{E}$. These components are computed as follows.

$$\begin{cases} \mathbf{Q} = \bar{\mathbf{C}} \times \mathbf{W}_{\text{Q}} + \mathbf{b}_{\text{Q}}, \\ \mathbf{K} = \bar{\mathbf{C}} \times \mathbf{W}_{\text{K}} + \mathbf{b}_{\text{K}}, \\ \mathbf{V} = \bar{\mathbf{C}} \times \mathbf{W}_{\text{V}} + \mathbf{b}_{\text{V}}, \end{cases} \quad (7)$$

Next, the matrix $\mathbf{E}$ of self-attention is computed by

$$\mathbf{E} = \text{Softmax}(\mathbf{Q}\mathbf{K}^T)\mathbf{V}, \quad (8)$$

where $\bar{\mathbf{C}}$ is the resulting matrix of Norm $(\mathbf{C})$ that stands for the function of layer normalization. $\mathbf{W}_{\text{Q}}$,$\mathbf{W}_{\text{K}}$,$\mathbf{W}_{\text{V}}$,$\mathbf{b}_{\text{Q}}$,$\mathbf{b}_{\text{K}}$, and $\mathbf{b}_{\text{V}}$ are weights and biases to be optimized likewise, respectively. Softmax $(\cdot)$ is employed as an activation function to implement normalization. In this paper, we employ a two-head attention layer. Therefore, the attention mechanism operated on two project versions of $\mathbf{Q}, \mathbf{K}$, and $\mathbf{V}$, producing intermediate attention values of $\mathbf{E}_1$ and $\mathbf{E}_2$, as described in Fig. 3. The final attention value is obtained by cascading and projecting them once again, which is expressed by

$$\mathbf{E} = [\mathbf{E}_1, \mathbf{E}_2] \times \mathbf{W}_{\text{E}} + \mathbf{b}_{\text{E}}, \quad (9)$$

where $\mathbf{W}_{\text{E}}$ and $\mathbf{b}_{\text{E}}$ represent weights and bias to be optimized of projection, respectively.

• *Multilayer Perceptron (MLP):* This module comprises two FC sublayers, and ReLU is utilized as the activated function for the first FC sublayer. The output of MLP can be calculated by

$$\mathbf{A} = f_{\text{ReLU}}(\text{W}_{\text{A}_1} \times \bar{\mathbf{E}} + \text{W}_{\text{b}_1}) \times \text{W}_{\text{A}_2} + \text{b}_{\text{A}_2}, \quad (10)$$

where $\bar{\mathbf{E}}$ is the resulting matrix of Norm $(\mathbf{E})$, W_{A_1}, W_{A_2}, b_{A_1}, and b_{A_2} are params of the first and second FC sublayers, respectively.

• *Layer Normalization:* Layer normalization serves the purpose of stabilizing the distribution of data features, leading to faster model convergence as well as reduced training duration.

Output layer: In this layer, the Sigmoid function, $f_{\text{Sigmoid}}(x) = \frac{1}{1+e^{-x}}$ is adopted as the activation function.

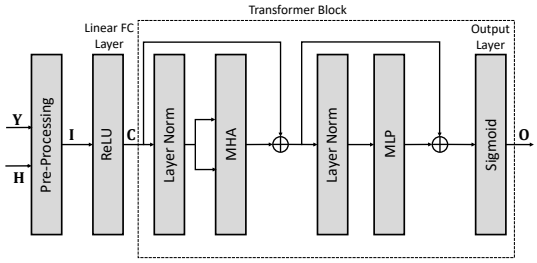

Fig. 2. Diagram of the proposed TransD3D-IM detector.

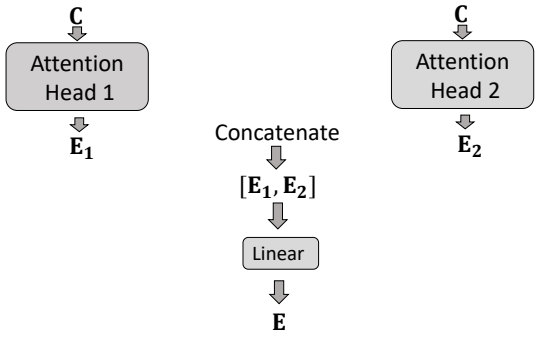

Fig. 3. Diagram of two-head attention.

Accordingly, the obtained matrix $\mathbf{O}$ of the output layer can be expressed by

$$\mathbf{O} = f_{\text{Sigmoid}}(\mathbf{W}_{\text{O}} \times \mathbf{A} + \mathbf{b}_{\text{O}}), \tag{11}$$

where $\mathbf{W}_{\text{O}}$ and $\mathbf{b}_{\text{O}}$ are weights and bias to be learned, respectively. The matrix of $\mathbf{O} = \{\mathbf{O}_1, ..., \mathbf{O}_{s_A+1}\}$ has the size of $[n \times (s_A+1)]$, where $\mathbf{O}_i \in \mathbb{R}^n$ with $1 \leq i \leq s_A+1$, provides soft probabilities for the corresponding symbols and the indices set of two mapper constellations based on the output layer of TransD3D-IM, which utilize Sigmoid as the active function that maps outputs in the interval (0,1). In fact, the proposed detector relies on the mechanism of the LLR-aided detection to recovered both indices and data separately corresponding to $\mathbf{O}$.

C. Model Training

Implementing into online TransD3D-IM detector is required sufficiently large offline training. In particular, various p-bit sequences are randomly generated and converted to the corresponding conveyed bits $\mathbf{X}$ according to the system model in Section II. Next, the processed signals are passed through the Rayleigh fading channel, where it is subject to interference from random AWGN noise. Channel and noise matrices are also randomly created and changed from one-bit sequence to another, according to their established statistical models. At the receiver, the obtained signal and CSI are pre-processed to obtain the training data. The conveyed signals $\mathbf{X}$ are transformed to the corresponding one-hot labels to enhance the accuracy of symbol recovery at the receiver side. For instance, suppose that sending a DM-IM-3D-OFDM subblock $[\mathcal{S}_A^1, \mathcal{S}_A^2, \mathcal{S}_B^1, \mathcal{S}_B^2]$ with via four subcarriers in Table I, the resulting one-hot label has the following form

$$\hat{\mathbf{O}} = \begin{bmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ 1 & 0 & 1 \\ 0 & 1 & 1 \end{bmatrix}. \tag{12}$$

Here, the row and column numbers of $\hat{\mathbf{O}}$ represent the number of subcarriers n and the constellation size $\mathcal{S}_A$ and $\mathcal{S}_B$, i.e., s_A and s_B, respectively. In particular, the first two columns indicate the order of 3D symbols in their corresponding constellations. Meanwhile, the last column shows the index selectors of the two mapper constellations. The index selector $\mathcal{S}_A$ corresponds to positions with a value of 0, while positions with a value of 1 indicate an index selector of $\mathcal{S}_B$.

The TransD3D-IM model performs a classification task to reduce the discrepancy among one-hot labels $\hat{\mathbf{O}}$ and the resulting matrix $\mathbf{O}$ of neural networks. Therefore, the binary cross-entropy (BCE) function is adopted as the loss function as follows.

$$\ell(\mathbf{O}, \hat{\mathbf{O}}; \theta) = -\hat{\mathbf{O}} \log_2(\mathbf{O}) - (1 - \hat{\mathbf{O}}) \log_2(1 - \mathbf{O}), \tag{13}$$

where θ is parameters to be learned of the model. The Adam optimizer [24] is employed and the learning rate is denoted by η. Aiming at achieving the best result, the training SNR level, presented as λ_{train}, must be carefully selected for training TransD3D-IM since it directly affects the detection performance.

IV. Simulation Results

In this section, we provide BER performance comparisons and runtime complexity of TransD3D-IM with its competitors, particularly ML, LLR, and the existing DL-based detector, term as DuaIM-3DNet [25]. As for TransD3D-IM, the linear FC layer has $q_{\text{linear FC}}$ nodes. We consider a two-head attention layer and implement MLP with two FC layers, which have q_{MLP} nodes. Meanwhile, the quantity of the hidden nodes of two subnets in the DuaIM-3DNet are denoted by q_{IndexNet} and $q_{\text{SymbolNet}}$, respectively. To ensure that DL-based detectors have fair performance, q_{IndexNet} and $q_{\text{SymbolNet}}$ have been used parameters as in [25], which are considered optimal parameters of DuaIM-3DNet model. These DL-aided detectors are trained for 100 epochs with every epoch consisting of 600 batches. The batch size used during training is set to 1000 epochs. The learning rate of $\eta = 0.001$ is applied for all parameters. In this paper, we consider the case with $(n, k) = 4, 2$ and use two types of params for all scenarios, namely Scenario 1 and 2, as shown in Table II. Our analyses are considered in scenarios with perfect CSI conducted in the Rayleigh fading channel where each entry is distributed by the complex Gaussian $\mathcal{CN}(0, 1)$.

A. BER Performance

In Fig. 4, we evaluate BER of TransD3D-IM in comparison with the current detectors versus SNR for Scenario 1 under perfect CSI channel condition. The DL-based detectors have been trained with $\lambda_{train} = 15$ dB. It can be seen that the

TABLE II
PARAMETERS FOR DNN-BASED DETECTORS

	s_A	s_B	DuaIM-3DNet		TransD3D-IM	
			q_{IndexNet}	$q_{\text{SymbolNet}}$	$q_{\text{Linear FC}}$	q_{MLP}
Scenario 1	2	2	768	768	32	128
Scenario 2	4	4	1000	1000	64	256

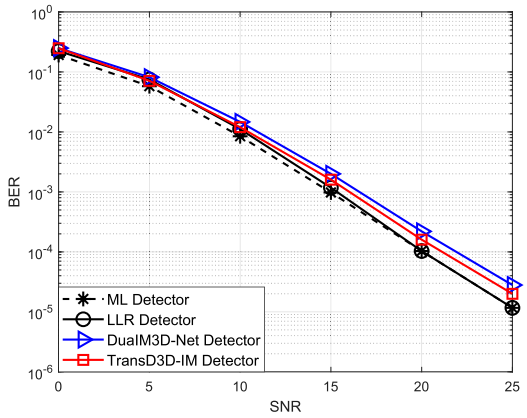

Fig. 4. BER performance of our proposed TransD3D-IM detector and the existing ones for Scenario 1.

proposed TransD3D-IM detector attains the BER performance approaching the model-based detectors and is slightly superior to the DuaIM-3DNet. For instance, the gap SNR between the Transformer-aided DL detector, LLR, and ML is negligible with less than 1 dB and 2 dB at BER of 10^{-3}, respectively.

Fig. 5 shows the BER performance of TransD3D-IM comparisons to its competitors versus SNR for Scenario 2 under certain CSI conditions. As shown in Fig. 5, we observed that TransD3D-IM achieves BER performance approximate to that of the model-aided detectors while significantly outperforming the existing DL-based detector. Considering at BER of 10^{-2}, the proposed detector is only inferior to ML and LLR by about 1 dB. Meanwhile, it has an edge over DuaIM-3DNet by about 5 dB. This indicates that differences in performance between various DL-aided detectors are increasingly evident. Our simulation results point out that TransD3D-IM can achieve nearly optimal BER performance in comparison with model-based receivers. Furthermore, our proposal exhibits more robustness than the current DL-aided detector while TransD3D-IM has significantly lower runtime complexity compared to its equivalents as detailed in the next section.

B. Runtime Complexity

We now compute the runtime complexity required for signal detection of the proposed detector and its competitors. All candidates are simulated using MATLAB on the same computer. The DNN model parameters are employed as presented in the previous subsection and its running time is calculated in online phase. We show the comparison of the resulting runtime of all models in Table III. It is clear that TransD3D-IM requires much less runtime than its counterpart under the same condition. Specifically, the runtime of TransD3D-IM is 460 times less than that of ML and 5 times less than that of LLR and DuaIM-3DNet detectors. This unequivocally validates the advantage of our proposal in terms of runtime.

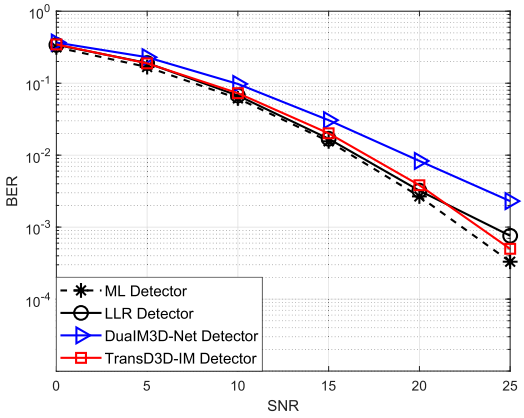

Fig. 5. BER performance of the proposed TransD3D-IM and existing detectors for Scenario 2.

TABLE III
RUNTIME OF PROPOSED TRANSD3D-IM AND ITS COMPETITORS IN MILLISECONDS

(n, k, s_A, s_B)	ML	LLR	DuaIM-3DNet	TransD3D-IM
(4,2,4,4)	12	0.134	0.136	0.026

V. CONCLUSIONS

In this work, we have put forward the TransD3D-IM detector for the DM-IM-3D-OFDM system. Specifically, we build a novel DNN model for TransD3D-IM based on the Transformer framework. Our proposal can comprehensively leverage the global dependencies and features of the obtained signal to produce nearly optimal BER performance. Under the Rayleigh fading channel with CSI certainty, TransD3D-IM can attain approximate BER performance in comparison with the model-based receiver. Besides, the proposed detector exhibits more robustness than the existing DL-aided method, especially when the model system parameters increase. Meanwhile, TransD3D-IM requires lower runtime complexity than its competitors. We believe that with such advantages, Transformer-based detectors may be an effective solution for signal detection in communication systems in the future.

***Abstract*—Recognizing human activities (HAR) from wearable motion sensors has widely practical applications due to its low cost, convenient use, and scalability. Plenty of works utilize 1D CNN or RNN to capture temporal information from time series, while others take advantage of 2D CNN architectures that can effectively handle spatial correlation, and distinctive recognition features, which are really useful for recognition tasks. This paper proposes GAFormer, a method, which exploits the latter, for human activity recognition from wearable motion sensors. GAFormer transforms the raw IMU data into a Gramian Angular Difference Field (GADF) image, which encodes the pair-wise angles between different sensor readings to capture the temporal dynamics and relationships among the sensor measurements. Next, a transformer model is employed to extract visual features from GADF images effectively. In addition, we adapted a state-of-the-art transformer CoAtNet as the backbone of GAFormer. GAFormer is evaluated over two published datasets C-MHAD and GesHome. With the accuracies of 98% on C-MHAD and 95.5% on GesHome's subset, GAFormer demonstrates that combining the GADF technique and a transformer model could be feasible and promising for motion sensor-based action recognition.**

***Index Terms*—Human activity recognition, inertial sensors, features extraction, Convolutional Neural Networks, Transformers, Gramian Angular Field.**

I. Introduction

Human activity recognition (HAR) has been an active research topic as it has diverse applications including, just a few to name, healthcare [1], security monitoring [2], and human-machine interaction [3]. Previously, cameras and motion sensors were commonly utilized to capture human activities. Although camera-based HAR has achieved a significant stride, it suffers several limitations such as privacy concerns and the recognition performance relies on the lighting conditions. The latter, however, has shown the feasibility of recognizing human activities everywhere while alleviating privacy invasion from the users. In addition, thanks to the proliferation of electronic devices and their low costs, motion sensors can be embedded in devices such as phones, watches, cars, and furniture. And they can be part of applications such as uninterruptedly and non-intrusively logging human motion information [4]. Therefore, human action recognition using wearable motion sensors (accelerometer and gyroscope sensors) inherits the advantages of mobility, compact size, low power requirements, and low cost.

In the literature, a number of methods for HAR from wearable motion sensors have been proposed. Traditional methods extracted hand-crafted statistical features from raw time series data and then input them to a classifier (e.g. SVM, Random Forest) [5]. Others proposed converting the raw signals by wavelet [6] or Fourier transforms [7] for better characterization of the signals. In recent years, with the increased development of deep learning, convolutional neural networks - CNNs [8], recurrent neural networks - RNNs (LTSM and Bi-LSTM and a combination of CNN with LSTM [9] have been widely exploited for motion sensor based HAR problems. Deep learning models have been shown to outperform the traditional methods [10], [11].

Sensor-based HAR often proposes a one-dimensional convolution kernel CNN that can easily handle time series, but it seems not effective to exploit the rich high-dimensional data features. To benefit from the advantages of 2D CNNs, several methods are used to convert the one-dimensional sensor data into two-dimensional data through matrix rearrangement. For instance, one-dimensional time series were converted to two-dimensional time-frequency images by Fourier transform in [12]. The Gramian Angular Difference Field was first introduced by [13] for converting time series into 2D images. In that work, GADF is inputted into a 2D CNN Fusion-Mdk-ResNet for activity classification [12], showing outstanding accuracy.

Motivated by this 2D representation, in this work, we employ the same Gramian Angular Difference Field technique to convert the time series data (accelerometer and gyroscope data) into a 2D image as [13]. However, we capture more of the dependency of features extracted from a 2D CNN by a CoAtNet-based transformer model [14]. CoAtNet was designed to recognize human activities from large datasets

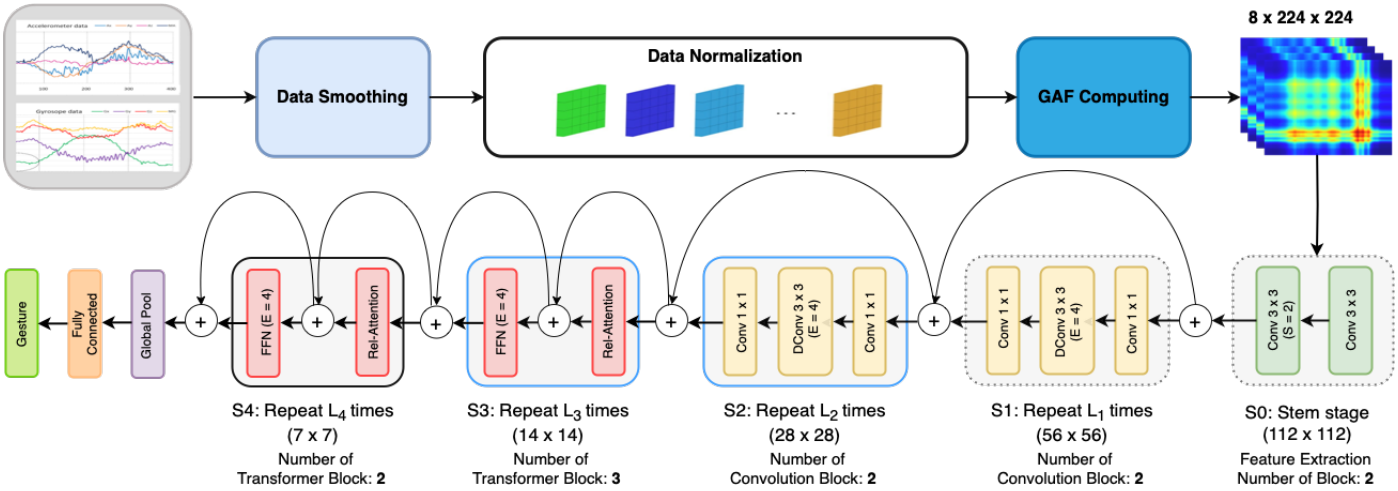

Fig. 1. Framework of GAFormer architecture for human activity recognition.

of RGB images that leverage the advantages of either CNNs or transformer models. In our work, GADF has different characteristics than conventional RGB images. In addition, the number of GADF samples is quite limited which is not suitable for transformer models. We then modify the original CoAtNet to fit better our problem. We name our proposed method GAFormer. The proposed method is validated on two datasets published in the research community C-HMAD [15] and a subset of GesHome [9] for the context of human-machine interaction. The results show that the proposed method achieves better results than the original methods.

In summary, the contributions of the paper are three-fold. Firstly, we propose a new method that combines GADF with a 2D CNN and a Transformer model. Second, we modify the transformer model to avoid overfitting when working with a small dataset in a new perspective (GADF) rather than conventional RGB space. Finally, we evaluate the performance of our proposed method on two public datasets showing promising results for activity recognition in human-machine interaction. The rest of the paper is structured as follows: We present the relevant works in section II. We introduce our framework in section III. Experiments and conclusions are presented in sections VI and V, respectively.

II. Related Work

In recent years, there have been many studies on user activity recognition using wearable devices for data collection. Two main approaches to feature learning for this problem are traditional machine learning methods and deep learning.

Regarding ML methods for extracting hand-crafted features using sensor data, these methods mainly extract features manually in the time or frequency domain to represent movements or activities. One of the recent studies [5] combined local and global features for action recognition from motion sensors. Some features, such as mean, energy, entropy, and frequency domain, are extracted through a sliding window, and then passed through different classifiers, such as SVM and Random Forest for gesture recognition. However, these methods all require complex and time-consuming feature engineering. The method based on deep learning avoids the step of feature engineering, enabling researchers to pay more attention to other aspects of HAR. In the work of E. Ramanujam et al. [16], the focus is on providing a profound and concise description of deep learning techniques used in smartphone and wearable sensor-based recognition systems. The proposed techniques are categorized into conventional and hybrid deep learning models, each with its own uniqueness, merits, and limitations.

Accordingly, several types of deep neural networks are commonly used to classify sensor signals in time series, such as Alemayoh et al. used an improved one-dimensional convolutional neural network (CNN) to classify the collected activity data [8]. Deng et al. [17] proposed two methods for activity image construction, transforming the sensor data into activity images by matrix rearrangement. Then, the CNN was applied to extract features and identify the types of activities. Uddin et al. proposed a multi-sensors data fusion network based on recurrent neural network (RNN) [18].

Nguyen et al. propose a 1D-CNN biLSTM architecture for 18 gestures using motion sensors [9] applied to home appliance control applications. BiLSTM allows time series to move in two directions: from past to future and from future to past. It works on the principle of two LSTM layers in one layer when the other layer is presented with a reverse copy of the original time series. Although the deep learning method has many advantages, it also has some unavoidable problems and disadvantages. The recognition methods based on RNN can only be carried out in sequence because the calculation of the next step in the training process depends on the results of the previous step, and the training process consumes a long time. Recognition methods based on CNN mostly use a one-dimensional convolution kernel which makes it difficult to fully exploit the rich high-dimensional data features.

Some signal-to-image conversion methods have also been

studied with positive results. Jiang et al. [19] use HAR inertia data to convert it into 2D active images, which they then feed into classifiers to improve performance. The active images were converted to the frequency domain and the spectral time domain using a discrete Fourier transform (DFT) and a 2D Wavelet transform, respectively. However, these images in different domains are used independently, and their union cannot be exploited. Xu et al. [12] used the method Gramian angular field (GAF) and deep CNN because of the weight sharing mechanism of CNN, the training speed of CNN is much faster than the other networks. At the same time, the GAF algorithm increases the interpretability of transforming from one-dimensional time series to two-dimensional images and also lays a foundation for the effectiveness of feature extraction. In 2021, Zeeshan Ahmad [20] also demonstrates the use of inertial sensor data using four types of spatial domain methods to convert inertial sensor data into active images. ResNet-18, a CNN model, is used to learn deep features from multimodality.

To combine the advantages of CNNs, RNNs, and self-attention networks, Vaswani et al.[21] designed a new architecture using centralization. This architecture, called Transformer, parallelizes by learning the response sequence with a centralized mechanism while also encoding the position of each element in the sequence. Dirgova et al. [22] also use the Transformer model for the direct application of deep neural networks to normalized time signal sequences from sensors using a different approach to time series processing. entirely based on the attention mechanism. The transformer model focuses directly on using the attention mechanism to find time series correlations between features and allows large parallelism of time series computations. However, this method is limited by the long computation time. To solve this problem, Zihang Dai [14] proposes a simple but effective network architecture called CoAtNet, which leverages strengths from both ConvNets and Transformers. In this study, it is shown that commonly used depth-first convolution can be efficiently merged into attention layers with relatively simple attention; stacking the convolution and attention layers in the appropriate manner can result in better efficiency, generalization, and capacity. CoAtNet not only enjoys the superior scalability of Transformer models but also achieves faster convergence and thus improved efficiency.

Our work in this paper will also convert the time series into an image using the Gramian Angle Field transform. Then, the generated image will be fed into the classification system, which is a combination of CNN and Transformer in image classification. Our methods and results will be presented in the following sections.

III. Method for action recognition from motion sensors

A. Proposed framework

Our proposed framework is illustrated in Fig.1. It is composed of four main steps:

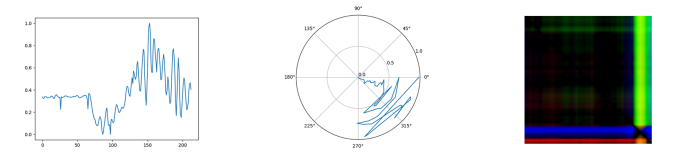
- Pre-processing: This step denoises the raw accelerometer, gyroscope data, and their magnitude by using a smoothing filter. The smoothed signals are normalized to the range [0, 1].
- GADF computing: This step takes the normalized signals and converts them into a 2D image using Gramian Angular Different Field transform.
- Extracting 2D embedded features: A 2D CNN is deployed to extract discriminative features from GADF images.
- Self-attention computing: The embedded features are passed through a stack of self-attention blocks to capture better their correlation.

In the following, we will describe each step in detail.

B. Pre-processing

1) Data smoothing: The data needs to be smoothed before being processed in our proposed GAFormer model to maximize the effectiveness of the method. In this paper, we simply use the following smoothing function:

$$x_i = \frac{(x_{i-2} + x_{i-1} + x_i + x_{i+1} + x_{i+2})}{5} \tag{1}$$



where x_i is the data signal at the time i. This formula is applied for all channels of accelerometer and gyroscope data and also the magnitudes of these two signals.

2) Data normalization: Let X be a real-valued time series of n samples $X = \{x_1, x_2, x_3, \ldots, x_l, \ldots, x_n\}$. We rescaled X into $\tilde{X}$ so that the value of each sample in $\tilde{X}$ falls between 0 and 1, which can be expressed as follows:

$$\tilde{x}^i = \frac{x_i - \min(X)}{\max(X) - \min(X)} \tag{2}$$

C. Gramian Angular Field

Wang et al. proposed Gramian Angular Field that encodes time series data into various types of images namely, Gramian Angular Summation/Difference Fields (GASF/GADF) and Markov Transition Fields (MTF) [13]. In this paper, we convert our time series from motion sensors by Gramian Angular Difference Field (GADF) to capture underlying dynamics while being easily processed by computer vision techniques.

(a) A rescaled one-dimentional time series in GesHome datasets (b) Transform time series into a polar coordinate system in GesHome datasets (c) GADF image in GesHome datasets

Fig. 2. Illustration of one-dimensional time series (left) converted to a 2D image (right) in the polar coordinate system (middle).

To this end, first, the normalized time series obtained from the pre-processing step is represented in the polar coordinates system. The value of the angular sine presents the angle while the time stamp presents the radius. The angular field is a new perspective of time series as time increases, the values

of angles will run along the circles of different radii. This encoding is formulated by the following equation.

$$\begin{cases} \phi_i = \arcsin(\tilde{x}_i), & 0 \leq \tilde{x}_i \leq 1, \tilde{x}_i \in \tilde{X} \\ r_i = \frac{i}{N}, & i \in N \end{cases} \tag{3}$$

where $\tilde{x}_i$ is the rescaled sample of the time series, i is the time stamp and N is a constant factor to regularize the span of the polar coordinate system. Then the Gramian Angular Difference Field is utilized to create the corresponding 2D image:

$$GADF(i,j) = \sin(\phi_i - \phi_j) \tag{4}$$

where $i,\ j \in [1, N]$, N is the length of internal time series data and varies to the activity sample. In our work, we consider three acceleromerter channels (a_x, a_y, a_z), three gyroscope channels (g_x, g_y, g_z) and their corresponding magnitude m_a, m_g. As a result, a tensor $N \times N \times 8$ is generated. We then resize it to $224 \times 224 \times 8$ for further processing steps. Fig. 2 illustrates an example of one-dimensional time series (left) converted to a 2D image (right) in the polar coordinate system (middle).

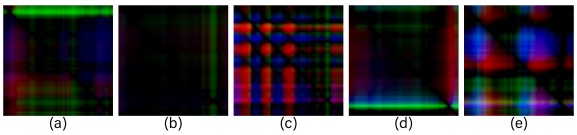


Fig. 3. GADF images generated from samples of five activities in C-MHAD dataset: (a) Swipe to left. (b) Swipe to the right. (c) Hand wave. (d) Draw a clockwise circle. (e) Draw a counter-clockwise circle.

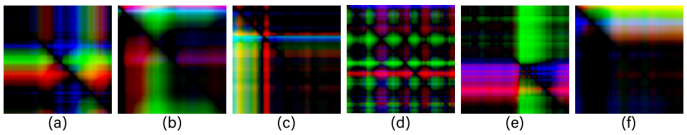

Fig. 4. GADF images generated from samples of five activities in GesHome dataset: (a) CCWCircle. (b) CWCircle. (c) Move down. (d) Move left. (e) Move right. (f) Move up.

Figure 3 and Figure 4 illustrate GADF images generated from time series of several activities in two experimented datasets. It is noticed that each activity generates a GADF which is different from others. That is a good characteristic for distinguishing the activities by the next steps.

D. Features extraction and classification

The GADF image generated from the previous step is inputted into a hybrid model that combines 2D CNN and Transformer. The idea to combine 2D CNN and Transformer is to boost the strengths of both models (generalization for CNN and capacity for transformer). In [14], Dai et al. have proposed a method, namely called CoAtNet, to efficiently hybrid the CNN and the Transformer.

CoAtNet combines the power of Convolutional Neural Networks (CNN) and Transformer networks. CNN aggregates local features from GAF images, while Transformer helps the model learn global relationships and extract important information from the data. This combination is demonstrated in the following form:

$$y_i^{\text{pre}} = \sum_{j \in \mathcal{G}} \left(\frac{\exp\left(x_i^T x_j + w_{i-j}\right)}{\sum_{j \in \mathcal{G}} \exp\left(x_i^T x_k + w_{i-k}\right)} \right) x_j \tag{5}$$

where $x_i, x_j, x_k \in R^D$ are the input at position i, j, k respectively, y_i^{pre} is the output at the position i before the Softmax normalization, w_{i-j} is the depthwise convolution kernel in CNN model and $\mathcal{G}$ indicates the global spatial space in transformer model. This formula combines convolution with self-attention to gather the information that shares the same receptive field $\mathcal{G}$. To enable the global convolution kernel without increasing the number of parameters, we consider w_i as a scalar as described in the original paper [14].

The architecture of CoAtNet is illustrated as a component in our GAFormer in Fig.1. It is composed of convolutions and transformers stacked together. As indicated in [14], the stack type C-C-T-T (C stands for Convolution and T stands for Transformer) has better generalization, model capacity, transferability, and efficiency then it is chosen to design CoAtNet in this work. Fig. 1 shows five stages S_0, S_1, S_2, S_3, S_4, the L_1 to L_4 may repeat several times. For convolution block, CoAtNet utilizes MBConv [23] because it was built upon depthwise convolutions so it can achieve both high accuracy and better efficiency. In the first block of each stage from S1 to S4, the down-sampling operator is performed independently for the residual branch and the identity branch. The global average pooling is applied to the last-stage output to get the representation.

CoAtNet has various versions (from CoAtNet-0 to CoAtNet-7) depending on the number of times the blocks in each stage are repeated. The higher version has more parameters but gives higher accuracy. However, some existing works have shown that Transformer scales better but its accuracy could be reduced compared to the CNN models. As a result, Transformer achieved only comparable performance when trained on a very large dataset. In this work, as we work on quite a limited dataset in a new perspective (GADF), we create a smaller CoAtNet, which we call CoAtNet-light by reducing the number of Attention Blocks. Table. I shows the configuration of our proposed CoAtNet-light compared with the smallest model CoAtNet-0. It is noticed that we keep the same number of channels but we change the number of repeat times at stages S_2 and S_3. Particularly, we reduce the number of Convolution Blocks (layer S2) from three to two, and the number of Transformer Blocks, in layer S3 from five to three. By doing so, we can avoid overfitting problems why lightening the size of models. As a result, the inference time is reduced (measurement by NVIDIA GeForce RTX 2080 Ti GPU) (Tab. II).

To sum up, GAFormer (GADF + CoAtNet-light) is a framework that combines the representation of motion data by GADF image and a CoAtNet-light network which is customized to fit better with the small-size datasets.

TABLE I
COMPARISON OF OUR COATNET-LIGHT WITH THE ORIGINAL COATNET-0

Stages	Our CoAtNet-light	CoAtNet-0
S0-Conv	L=2 D=64	L=2 D=64
S1-MBConv	L=2 D=96	L=2 D=96
S2-MBConv	**L=2** D=192	L=3 D=192
S3-TFM	**L=3** D=384	L=5 D=384
S4-TFM	L=2 D=768	L=2 D=768

TABLE II
COMPARISON NUMBER OF PARAMETER AND INFERENCE TIME BETWEEN GADF+COATNET-0 AND OUR PROPOSED GAFORMER

Method	Number of parameters	Inference time
GADF + CoAtNet-0	$19.03M$	$19.75ms$
GAFormer	$13.49M$	$15.42ms$

IV. EXPERIMENT

A. Datasets

We use two available datasets to evaluate the studied method, including C-MHAD [15] and GesHome [9]. The data of each gesture/activity used will include six signals: three signals in x, y, z axes of the accelerometer sensor and three signals in x, y, z axes of the gyroscope sensor. The details of each data set are described as follows:

- **C-MHAD[15]**: The continuous dataset contains five hand gestures for controlling smart TVs performed by 12 subjects (ten males and two females). The three-axis acceleration and three-axis angular velocity signals of the Shimmer3 wearable inertial sensor were fed in real time to a laptop via a Bluetooth link at a frequency of 50 Hz. It includes 41,410 samples split into a training set (41,310) and a test set (100). Each sample is then normalized and converted to GADF images and illustrated in Fig. 3.
- **GesHome*[9]**: The GesHome dataset includes 18 hand gestures from 20 non-professional subjects of various ages and occupations. Participants performed 50 reps of each movement for five days. Consequently, the number of collected data is 18,000 gesture samples, including three-axis linear acceleration and three-axis angular velocity with a frequency of 25 Hz. In our experiment, to demonstrate the effectiveness of the method and its application to the problem of controlling smart home devices, we choose six main gestures in the dataset focusing on using hand gestures to simulate device control for experimentation leading to only 9,689 samples available. We name this dataset GesHome*. Each sample in the dataset is normalized and then converted to the corresponding Gramian Angle Difference Field (GADF) image as shown in Fig. 4. We divided this dataset into two subsets, the training set with 7,843 samples and 1,846 samples of the test set.

B. Experimental results

The experiments are conducted on these two datasets. There are four combinations of GAF and CNN, namely GASF+CoAtNet-0, GADF+CoAtNet-0, GADF+ResNet50, and GAFormer. In addition to accuracy, we also provide some metrics, such as Precision, Recall, and F1-Score, to evaluate models. The results are illustrated on Tab. III, Tab. IV, respectively.

TABLE III
PERFORMANCE COMPARISON ON C-MHAD DATASET

Method	Accuracy (%)	Precision (%)	Recall (%)	F1-score (%)
Baseline [15]	96.48	-	-	-
GASF + CoAtNet-0	95.00	94.20	94.80	94.40
GADF + ResNet50	94.00	93.96	94.00	93.80
GADF + CoAtNet-0	98.00	97.60	97.80	97.80
GAFormer	**98.00**	**97.80**	**98.20**	**98.00**

TABLE IV
PERFORMANCE COMPARISON ON GESHOME* DATASET

Method	Accuracy (%)	Precision (%)	Recall (%)	F1-score (%)
1D-CNN-biLSTM [9]	91.77	92.33	91.66	91.66
GASF + CoAtNet-0	72.91	73.16	72.67	72.16
GADF + ResNet50	90.00	90.16	89.83	90.33
GADF + CoAtNet-0	93.31	93.42	93.21	93.23
GAFormer	**95.50**	**95.50**	**95.33**	**95.40**

- **C-MHAD dataset:**

In this dataset, the results of all four combinations are compared with the baseline method introduced in [15] as in Tab. III. The baseline method's accuracy is 96.48%, an average of five reported actions' accuracy. Firstly, the model with the lowest accuracy combines GADF and ResNet50, with only 94%. Secondly, the CoAtNet-0 model, combined with GASF and GADF transformations, could achieve 95% and 98% accuracy, respectively. These results indicate that GADF seems better than GASF in these tasks. Regarding our proposed GAFormer method, with an accuracy of 98.00 % compared to 96.48 %, our method could overcome the previous study. Although these results, including precision, recall, and f1-score, are slightly better than those of GADF+CoAtNet-0, GAFormer is still a preferred choice thanks to its number of parameters and inference time, as Tab. II indicates.

- **GesHome* dataset:**

Similar to the C-MHAD dataset, we also compare our proposed method with the original work, combining 1D-CNN and biLSTM. In this dataset, we re-implemented it with less action, leading to an accuracy of 91.77%. The first thing to notice is that the GASF + CoAtNet-0 method has the lowest performance compared to the other methods, with the accuracy of this method at only 72.91 %. Next is the

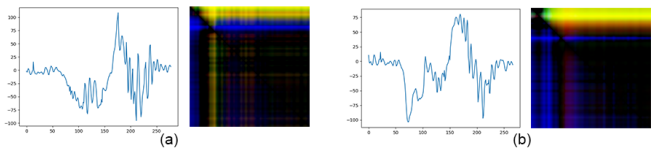

Fig. 5. Confusion image in GesHome datasets: (a) Image in CWCircle gesture. (b) Image in Move-left gesture.

GADF + ResNet50 method, with an accuracy of 90.00 %. The results of this method are relatively high but still lower than the baseline. Another combination, GADF + CoAtNet-0, has excellent performance with an accuracy of 93.31 %. The proposed GAFormer reaches 95.50 % yielding superior performance in terms of accuracy, precision, recall, f1-score, and the number of parameters. Tabs. IV shows the best performance of GAFormer compared to other methods and is highlighted with bold text.

V. Conclusion

In this work, we introduced a new method GAFormer for human activity recognition from wearable sensors. The method first transforms the motion data into Gramian Angle Difference Field (GADF) to create a 2D image. To extract the features from the image, we proposed a light version of CoAtNet that achieved better accuracy while reducing the inference time and the model size. Our method has been validated on two public datasets showing better accuracy than existing methods. In the future, we will deploy the method for continuous recognition from motion sensors in a practical application of human-machine interaction.

***Abstract*—Muscle fatigue onset detection and estimation have applications in supporting athletes during strength training. In this paper, the problem of surface electromyography (sEMG) based binary classification of fatigue and non-fatigue of human muscle activity during strength training is addressed. Further, the learned model is used to determine the fatigue onset using sEMG signals corresponding to a training activity. A novelty of this work is the analysis of the proposed machine learning method under different measurement conditions, such as varying postures, experience levels and lifting loads. A novel sEMG dataset titled ElectroMyography Analysis of Human Activities - DataBase 6 (EMAHA-DB6) is developed for strength training activities. EMAHA-DB6 includes sEMG signals collected from the seven prominent muscle sites of the right arm of 11 subjects engaged in strength training. The participants performed five distinct training exercises using three load weights in two body postures. A set of wavelet and time domain features are extracted and the support vector machines are used to classify them. Based on the binary testing results from a given time series, the fatigue onset is estimated using the majority voting. The SVM model is compared with other classifiers in terms of testing accuracy in the mentioned measurement scenarios. The SVM has outperformed the other models with a test accuracy of 86.5% under all conditions scenario. In terms of the impact of measurement conditions, the SVM has 94% in the low load condition, 88.5% in the stand posture and nearly 88% in the case of subjects with intermediate training status. Finally, in the proposed approach, the estimation of the fatigue onset has an average relative error of 12%.**

I. Introduction

Background: Muscle fatigue is a common physiological phenomenon that occurs due to prolonged or intense muscle activity, including strength training [1]. Fatigue due to strength training primarily results in reduced nerve signal strength that regulates muscle movement, leading to a reduction in muscle output force and has the potential to cause muscle damage and increase the risk of joint-related issues [2]. So monitoring changes in muscle strength and endurance over time during strength training can provide important insights into fatigue onset and help identify strategies for preventing injury and promoting recovery. In applications such as usage of prosthetics and rehabilitation, an accurate prediction or atleast estimation of fatigue is essential for optimal outcomes. In the context of prosthetics, the estimation of fatigue is crucial because it helps prevent potential damage to the muscles and other tissues surrounding the prosthetic, as well as injuries and accidents that may occur due to decreased ability to control the prosthetic limb. By identifying and addressing muscle fatigue early on, such incidents can be minimized. In the context of rehabilitation, fatigue onset estimation is crucial for improving efficiency to minimize its adverse affects on the recovery process. Notably, predicting fatigue in the lower extremity has proven to significantly enhance the recovery of stroke patients by facilitating longer exercise duration and promoting active participation in the rehabilitation process [3].

There are various approaches available for direct or indirect onset detection and estimation of muscle fatigue, such as measuring lactate concentration [4], analyzing surface electromyography (sEMG) signals, and studying gait parameters [5]. Among these, sEMG is commonly used as a non-invasive estimation method because sEMG represent muscle contractions and can be utilized to characterize muscle fatigue [6][7][8]. In recent years, there were several studies with focus on differentiating between sEMG signals in non-fatigue and fatigue conditions during dynamic contraction. One such study utilized multivariate multifractal detrending moving average (MMFDMA) algorithm to extract features from the singular spectrum and differentiated between non-fatigue and fatigue conditions [9]. Another study investigated the detection of muscle state based on the working principle of synergistic muscles and combination of signals from different muscle groups [10]. Additionally, in another study different fatigue estimation algorithms and assessment methods are compared to understand intra and inter-subject separability of fatigue levels. Further comparative assessment was carried out at three different load levels, demonstrating the importance of considering various measurement conditions [11]. Most recently, a classification analysis of non-fatigue and fatigue data was carried out to determine the onset of fatigue using multi-modal data. These sensor modalities included EMG sensors, computer game data, and perceived data [3]. These studies demonstrate the importance of using ML techniques to detect and predict fatigue in various conditions, including rehabilitation exercises. The existing research does not address the problem of classification based fatigue onset estimation and there is no clear understanding of role of different measurement conditions during estimation.

Contributions: The key contributions of this study include 1) development of a dataset of multi-channel sEMG signals collected during weight training under various measurement conditions, 2) development of a machine learning framework for classification of segments of the sEMG signal into fatigue and non-fatigue categories, 3) a fatigue onset estimation framework based on the results from the classifier and 4) analysis

979-8-3503-0067-3/23/$31.00 ©2023 IEEE

of the classification scheme with respect to the measurement conditions.

II. Data Description

A. Data Collection

In this paper, a new sEMG signal dataset named: ElectroMyography Analysis of Human Activities - DataBase 6 (EMAHA-DB6) is developed. The EMAHA-DB6 consists of multi-channel sEMG signals acquired during various strength training activities under different conditions described as follows. The study involved 11 healthy strength training enthusiasts (subjects) comprising 10 males and 1 female with an average age of 20 years and an average body weight of 68kg. The selected subjects provided their voluntary written consent. The measurements and the research were approved by the Institutional Ethics Committee of IIIT Sri City in accordance with the "National Ethical Guidelines for Biomedical and Health Research involving human-participants" of India and in general accordance with the Declaration of Helsinki. As shown in Table I, based on the strength training status [12], the subjects were categorized into three levels and the number of subjects at each level are: 3 at advanced, 4 at intermediate, and 4 at beginner level. Again as shown in Table I, to investigate the effects of fatigue resulting from prolonged and intense physical activity, each subject was assigned three different loads based on their experience level and body weight. In this study, as shown in Table II, the subjects are asked to perform five different exercises with three different loads and two different postures. Note that in this work, the fatigue onset is defined as the moment the subject experienced a reduction in strength and they were instructed to halt the activity exactly at the end of second curl from the onset.

TABLE I
RECOMMENDED WEIGHTS FOR DIFFERENT LEVELS OF EXPERIENCE

Experience Level	Load Weights	Body Weight	Experience
Beginner	2.5 kg 5 kg 7.5 kg	50 - 60 kg	0 - 6 months
Intermediate	5 kg 7.5 kg 10 kg	60 - 70 kg	6 - 12 months
Advanced	7.5 kg 10 kg 12.5 kg	70 - 80 kg	12 - 18 months

TABLE II
EMAHA-DB6: STRENGTH TRAINING ACTIVITIES AT DIFFERENT LOADS

Activities	Load Weights	Postures
One Arm Overhead Tricep Extension One Arm Tricep Kickback Reverse Dumbbell Zottman Curl Dumbbell Hammer Curls Rear Front Rotations	Min Load Mid Load Max Load	Sit Stand

Each hand muscle activity is recorded with a 7-channel Noraxon Ultium wireless sEMG sensor setup at 4000 samples per second. Self-adhesive Ag/AgCl dual electrodes were placed at the centers of the seven representative muscle sites of the right arm. Prior to a measurement session, each subject is informed about the experimental procedures and instructed to avoid food consumption within two hours before the session and refrain from alcohol consumption for at least 24 hours leading to the experiments. During the experiment, the subjects are encouraged to consume water and soft drinks but are advised to avoid dairy products. For a given subject, the strength training experiment consisted of two sessions lasting up to one hour each. During the first session, in the *stand* posture, a subject performed the above mentioned training activities with three loads according to the training status and adhering to the fatigue based stopping protocol described above. In the second session the same set of activities and the fatigue protocol are repeated in the *sit* posture. Each activity involved two phases: a rest phase and an action phase. During the rest phase, subjects are allowed to relax. Once they felt ready, they transitioned to the action phase and actively engaged in the specified activity. The subjects discontinued the activity exactly after the second curl when they were in need of rest. Specifically, in the action phase, the maximum time recorded was 240s for the rear-front rotations with the min load. On the other hand, the minimum time observed was 15.25s for the one-arm tricep exercise with the max load. The average duration of all activities during the action phase is approximately 60.5 seconds.

III. Methodology

As shown in Fig. 1, the proposed methodology for fatigue classification and onset estimation consists of five stages: 1) data preparation consisting of preprocessing and signal labelling, where the data converted into patterns suitable for supervised learning, 2) segmentation and feature extraction, where the patterns are converted into feature vectors, 3) training: where a classification model is chosen and trained with the labelled data, 4) testing and analysis, where the trained model is used to test on unseen trials and optimized; and finally, 5) onset estimation, where the optimized model is used to determine the onset of fatigue based on majority voting on binary output from classification.

A. Data Preparation

The data preparation stage of this study involved two steps:Preprocessing, and signal labelling.

1) Preprocessing: The multi-channel sEMG signals are processed by a high pass filter with a cutoff frequency at 20Hz to remove low-frequency noise for example due to mechanical artefacts. To eliminate the power line noise, a band-stop filter at 50Hz is also applied.

2) Signal Labelling: In this study, a self-report based approach is adopted for signal partitioning into fatigue and non-fatigue. Specifically, the delineation is based on a subject's own report of inability to continue and need of rest leading to discontinuing the activity. Furthermore, sections of the sEMG time-series corresponding to the two closing curls of the activity are assigned the label "*fatigue*" and represent periods of fatigue as experienced by the subjects. On the other hand,

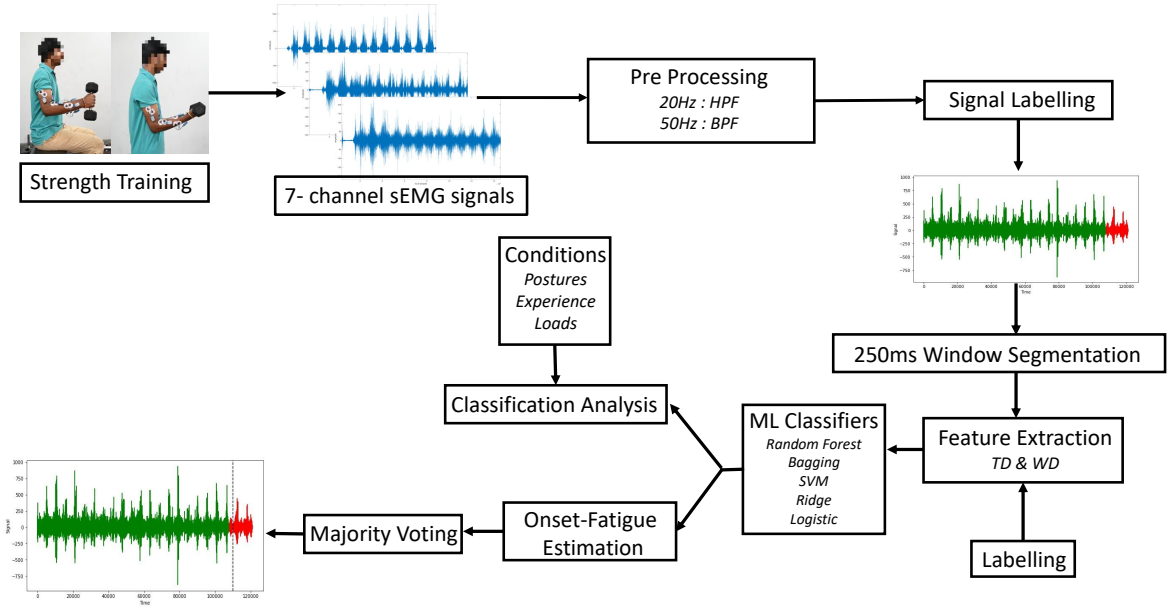

Fig. 1. Block Diagram for the Fatigue Classification and Onset estimation

the rest of the signal excluding the these two curls is labelled as "*Non Fatigue*".

B. Feature Generation

To facilitate classification, filtered signals are segmented into fixed length windows of 250ms duration. This window size is chosen to capture the short-term temporal dynamics of the muscle activity and provide sufficient resolution for further analysis. In the study, features are extracted for these 250ms segments. Feature extraction is performed in various domains, including time domain [13][14], frequency domain [15], wavelet domain [16], and eigenvalues, resulting in a total of 30 features. Class labels are then assigned accordingly.

C. Model Training

To balance the features from different modalities, the feature vectors are min-max scaled. This process standardized the data to enhance the performance of the classification models. During the training phase, to mitigate the significant class imbalance in the dataset, only 25% of the *non fatigue* segments in an activity are retained for further analyses. The scaled features are fed as input to the classification model for training. The classification algorithms analyzed in this study include the random forest (RF) classifier, bagging classifier, support vector machines (SVM), logistic regression (LR), and ridge classifier. These models were specifically selected due to their established effectiveness in binary classification tasks.The objective is to assess the classification performance from multiple perspectives and identify the most effective model for this task.

D. Testing and Analysis

For evaluating the performance of the trained models, in the testing phase, leave one activity out strategy is employed. Specifically, the feature vectors of segments of the left out activity are classified by the trained model and the classification performance is analysed as an average across the tested feature vectors. The performance metrics, include the confusion matrix and the classification accuracy. These metrics provided valuable insights into the effectiveness of the models in classifying the data into *Non Fatigue* and *Fatigue* segments.

E. Onset Estimation Framework

The onset estimation framework is described as follows. From Fig. 1, the classification model that provided the best performance during the testing phase is chosen as the onset estimator. This estimator is used to segregate the sEMG time series into *non fatigue* and *fatigue* partitions. To improve the quality of segregation a window based majority voting is employed. This window is equivalent to 10% of the signal length. In the majority voting approach, the predicted labels from multiple component segments of the time-series are aggregated. The label that occurs most frequently is considered the winner and an estimate of fatigue onset is obtained.

The performance of the onset estimation framework is analyzed as follows. For each activity set for estimation, the absolute error between the actual onset and the estimated onset through the previously described segregation process is determined. These errors are scaled by the length of the time series and statistics of the relative errors are reported. Furthermore, for visual inspection, the time series of a few

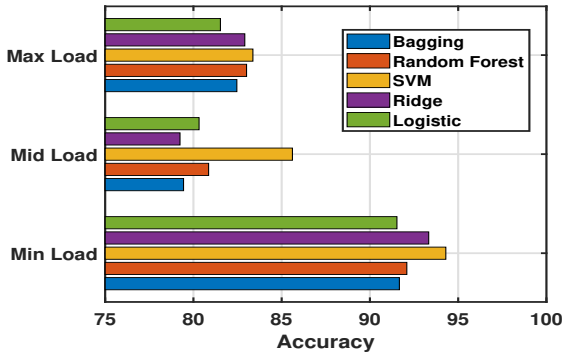

Fig. 2. Influence of Loads on Classification Performance.

sample signals with the segregated *non fatigue* and *fatigue* sections of the time series are plotted. Thus a combination of quantitative analysis and visual interpretation are used for performance assessment of the proposed onset estimation framework.

TABLE III
MODEL PERFORMANCE IN AGGREGATE DATA SCENARIO (EXPERIMENT 1)

Model	Accuracy (%)
SVM	86.51
Random Forest	85.08
Bagging	84.63
Ridge	84.4
Logistic	83.92

IV. IMPLEMENTATION AND RESULTS

A. Classification Experiments

In this study, various classification experiments are conducted to analyze the performance of the model under different measurement conditions. Note that in each of these experiments, the leave one activity out (LOAO) strategy is used for testing performance analysis.

1) Experiment 1: Aggregate Analysis: In this experiment, the activities from different body postures, lifting loads and training status levels are aggregated for classification performance analysis. The subsets of features mentioned are analyzed for optimal classification performance.

2) Experiment 2: Influence of Weights: In this experiment, the feature data is divided into three sets based on the training loads used by the subjects, namely, min, mid and max loads. The classification model is trained and tested separately on data from each group using the LOAO mechanism. The model performance is evaluated for each group and the average performance is reported.

3) Experiment 3: Influence of Postures: The experiment for understanding the impact of body postures has three different categories.

(i) Intra posture analysis: The classification model is trained and LOAO tested on the feature vectors from the same posture eg. *sit* posture. The experiment is repeated for the data from the *stand* posture.

(ii) Inter posture analysis: In the first phase of this analysis, the ML model is trained on feature vectors from the *sit* posture and tested on the data from the *stand* posture. Note that in this stage, the entire data from the other posture i.e., *stand* is tested. In the second phase, the order of postures is reversed.

(iii) Mixed posture analysis: In this category, in the first phase, the entire data from the *sit* posture and 30% of data from *stand* posture is used for training. For testing, the remaining 70% of the *stand* dataset is used. Note that the $30 : 70\%$ split is based on activities within the posture category. Again in the second phase, the process is vice-versa.

4) Experiment 4: Influence of Training Status: An experiment similar to the experiment 2 is conducted by dividing the data into sets based on subjects' training status advanced, intermediate, and the beginner. Again the training level performances are analyzed and the average is reported.

B. Classification Results and Analysis

1) Aggregate analysis: In this experiment, among the feature subsets tested, the combination of wavelet and time domain features demonstrated the best performance. Hence, these specific feature subsets are selected for further analysis. Table III shows the results of the testing in the aggregate data scenario from experiment 1. The SVM classifier outperforms the other classifiers with an average LOAO accuracy of 86.51%. The RF and the Bagging methods follow with 85% and 84.6% respectively.

2) Influence of Loads: Fig. 2 shows the model's test accuracy from the second experiment. The results show that there is clear dependence of performance on the activity load. For example, when training and testing on activities with the minimum load, highest accuracy of 94% for the SVM is observed. It indicates the model is effective in detecting gradual onset of fatigue, which is often associated with lower loads. On the other hand, when training and testing on the medium load, the model demonstrates 8% decline, suggesting its reduced ability to classify slightly intense fatigue situations. Finally, in the case of maximum load, the performance reduces to 83% a reduction of 11% in accuracy. This clearly indicates reduced classification capability in the case of fatigue related to maximum load.

3) Influence of Postures: Fig. 3 shows the results of the third experiment. It is observed that the SVM outperforms the other models by a decent margin in each of the categories of this experiment. For the SVM, the lowest performance is 83% and the highest is close to 89%. The performance of the models is clearly sensitive to different schemes in the third experiment. In the intra posture analysis, the performance in the case of *stand* posture is generally higher by 4% compared to the case of *sit* posture. In the inter posture analysis, when the model is trained on data from *sit* posture and tested on data from *stand*, a posture never trained, there is a slight decline in performance. In the mixed posture analysis, when only 30% of data from *stand* posture is introduced in training, the

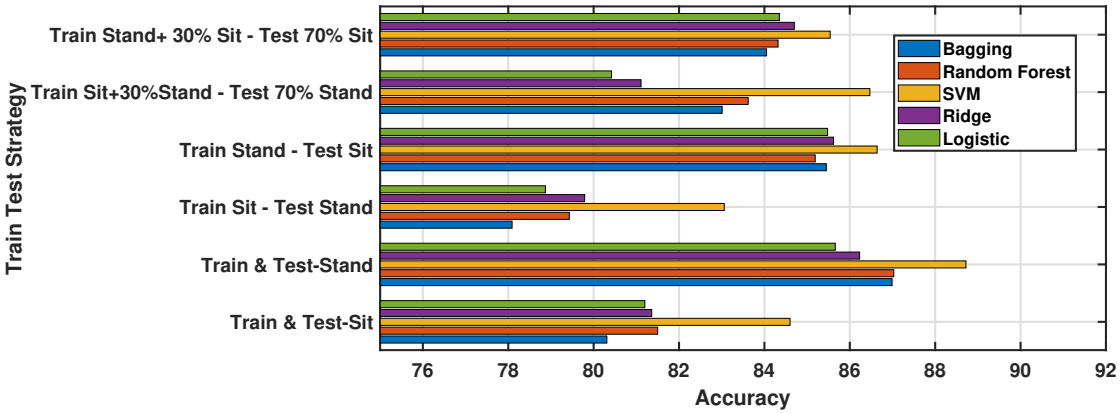

Fig. 3. Influence of Postures on Classification Performance.

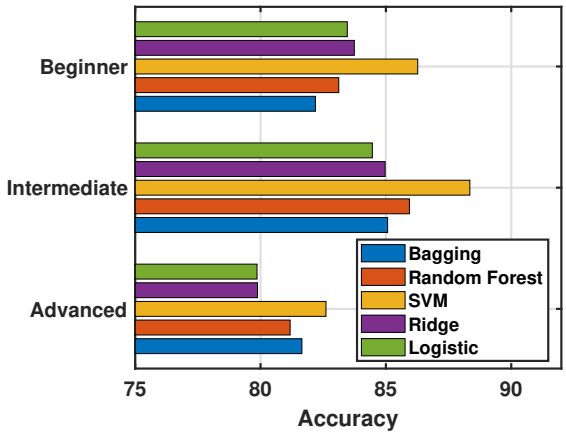

Fig. 4. Influence of Experience on Classification Performance.

model's performance improves by at-least 3%. This suggests that including a data from different postures in the training phase has a positive impact on testing accuracy. It should be noted that the performance of the model on the data from *stand* posture remains consistent across the different scenarios. In other words, the model seems more sensitive to data from *sit* posture. Overall, the model seems capable of generalization to data from new postures, for example see *Train Stand - Test Sit* results in Fig. 3.

4) Influence of Experience: Fig 4 shows the test accuracy results from experiment 4. Again the SVM outperforms the other classifiers. The average classification performance shows slight sensitivity to the strength training status of the subjects. For example, for the data from the *intermediate* training status, the model has higher performance of 87% compared to the other two levels.

C. Onset estimation analysis

Using the error analysis described in section III-E, the error percentages for the onset estimation are evaluated. The results revealed a minimum error of 0.43%, indicating a high level of accuracy in the onset estimation in some scenarios. On the other hand, the maximum error observed is 67.2%, suggesting instances where the model struggled to estimate the fatigue onset. The average error is 12.635% with a standard deviation of 13.14%. These findings show the possible range of performance outcomes, with some cases having excellent accuracy while others exhibiting more significant errors. These results underscores the need for further research. Fig. 5 illustrates the optimal onset estimation, revealing a 1-segment gap (250ms) between the actual and estimated onset location. In Fig. 6, the average onset estimation is depicted, exhibiting a 26-segment gap equivalent to 6.5 seconds. Both results demonstrate advanced reporting of fatigue onset.

V. Conclusion and Future Work

A. Conclusion

In this paper, a novel sEMG dataset, EMAHA-DB6, for strength training activities under different measurement conditions is developed. An ML based approach for fatigue vs. non-fatigue classification of sEMG signals followed by fatigue onset estimation is demonstrated. In the classification stage, several experiments are conducted to analyze the impact of measurement conditions on the classification performance. In the first experiment, the SVM model achieved an highest accuracy of 86% compared to the other models. In the second experiment, the best accuracy ($> 93\%$) is achieved by the SVM in the low load conditions. In the experiment three, the SVM achieved an accuracy of 88.5%. This suggests that the posture of the subjects plays a vital role in the accurate classification of fatigue. In addition to classification, fatigue onset is estimated using the sEMG signals for strength training activity. The estimation performance is evaluated by comparing it with the actual onset. An average error of 12% showcases the promise of our method.

B. Future Work

The future plans include further studies on the fatigue classification and onset estimation. Specifically, deep learning models such as the U-Net designed for time series analysis can be explored. One challenge is to determine if the model can classify and estimate the fatigue onset on data from entirely

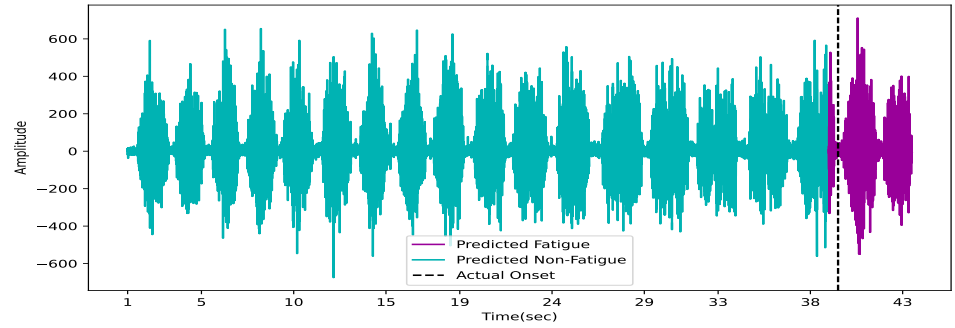

Fig. 5. An illustration of fatigue onset estimation: lowest error performance

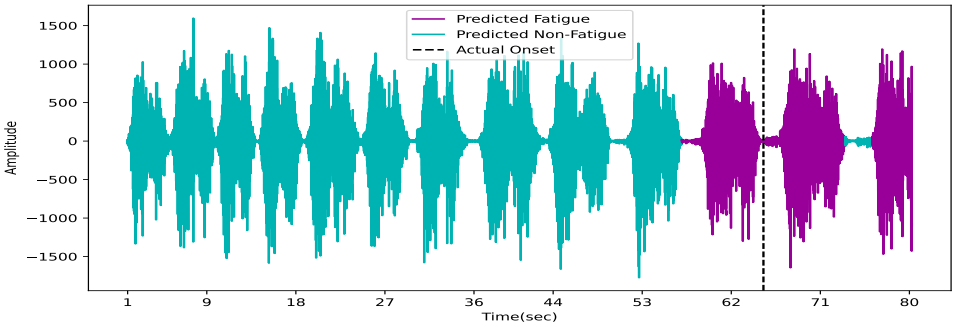

Fig. 6. An illustration of fatigue onset estimation: average error performance

new subjects without further training. In terms of measurement conditions the lifting load and the subject's training status can be further analyzed. Finally, another objective is to determine the amount of training data needed for optimal fatigue classification and onset estimation.

Abstract — **Visual attention is a function of the brain that allocates its computational resources to enable us to attend to the most important visual information. In actual driving, there are many perceptual objects such as pedestrians, signals, and other vehicles, etc. To selectively recognize these traffic objects for safe driving, the driver's gaze is appropriately controlled under visual attention. It is known that the P300 event-related potential related to visual attention, and is an essential brain activity to understanding the visual-attention characteristics in visual search. Although the P300 response reflects visual attention, the response characteristics of the P300 especially regarding the multiple object search are largely unexplored. To understand the brain activity on visual attention for multiple objects, we measure the P300 response and examined especially its characteristics for the types of traffic objects in terms of the capacity of induction for visual attention.**

I. INTRODUCTION

Traffic accident is one of the crucial social problems. Recent highly developed various types of intelligent transport systems (ITS) contribute to reducing the occurrence of traffic accidents [1]. In spite of this development of ITS technology, human error-related traffic accidents are difficult to prevent [2].

A variety of human errors leading to traffic accidents such as miss perception, oversight, distracted driving, careless driving, etc. [2-7] is known, and most of those factors are related to vision. During vehicle driving, 90% of the information related to driving is based on vision. During driving, information on the driving scene is visually grasped and processed in the brain to determine appropriative driving behavior. In this processing, previously mentioned human visual processing errors lead to delays in the detection of traffic objects such as pedestrians, other vehicles, signals, etc., then these also make lose control of vehicle maneuvers. Given these factors, it is essential to understand brain signal processing regarding driving attention and perception in order to reduce road traffic accidents of visual origin.

Visual attention is a function of the brain that allocates its computational resources to enable us to attend to the most important current information [8]. In actual driving, there are many perceptual objects such as pedestrians, signals, and other vehicles, etc. Therefore, the driver should distribute the computational resource of visual attention to these objects due to that their recognition is closely related to safe driving behavior. The distribution of visual attention during driving was revealed by eye movement research—shifting attention to the side lane [9], fixating on the location where the vehicle will be in the next few seconds [10], varying the covered field of view (e.g. [11-13]). On this process, it is revealed that the attentional shift is related to the visual saliency that is determined by visual information of the scene such as color, intensity, orientation [14-16]. Despite large amounts of evidence for visual attention and visual search during driving, the brain activity for visual attention in visual search of multiple objects is largely unexplored.

In the present study, we focused on event-related potential P300, which is strongly correlated with visual attention [17,18], to explore the brain activity in the visual search of multiple objects during driving. To further investigate relationship between P300 and visual perception in driving, we examined the characteristics of P300 for the different types of traffic objects in terms of the capacity of induction for visual attention.

II. METHODS

A. Subjects

This study recruited 11 healthy male subjects aged 21-24 (22.18±1.03) years to participate in EEG measurement during visual perception of multiple traffic targets. All subjects had a

979-8-3503-0067-3/23/$31.00 ©2023 IEEE

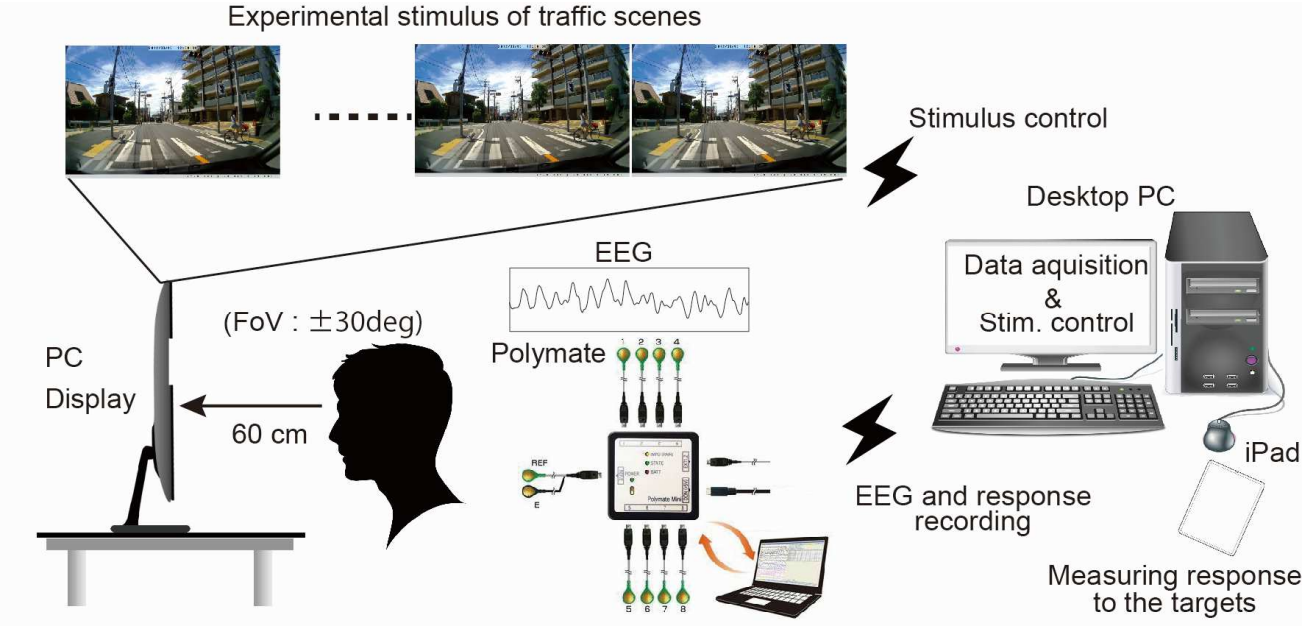

Fig. 1. Experimental setup for stimulus control, EEG and response recording.

valid driver's license, normal or corrected-to-normal vision using glasses or contact lenses which was specified in the license, and presented normal EEG. Here, we checked the arousal condition of the subjects using the Karolinska Sleepiness Scale [19] translated into Japanese, and subjects who reported more than level 3 (criteria of drowsy) did not participate in the experiments.

B. Experimental setup

Figure 1 illustrated the experimental setup for measuring EEGs during visual perception of the traffic objects. The experimental setup includes a chin rest, a driver's seat, , display (1920 × 1080), iPad utilized for measuring response to the traffic targets in perception, and a personal computer (PC) utilized for stimulus control and EEG acquisition. The 34 scenes of the vehicle driving were utilized as the visual stimulus. The distance between the projected PC display and the subject was maintained at 60 cm, which simulated the experience of watching traffic scenes from the driver's seat in a vehicle, and this condition imitates the field of view was ±30°, which encompassed the functional field of view during driving (approximately ±20°) [20].

C. Experimental Stimulus

We utilized 34 driving scenes captured by video camcorder in the experiments. In preceding the experiment, we carefully searched the traffic objects including road signs, signals, other vehicles, pedestrians, cross road, and intersections, which need perception for safe driving, and determined the timing of

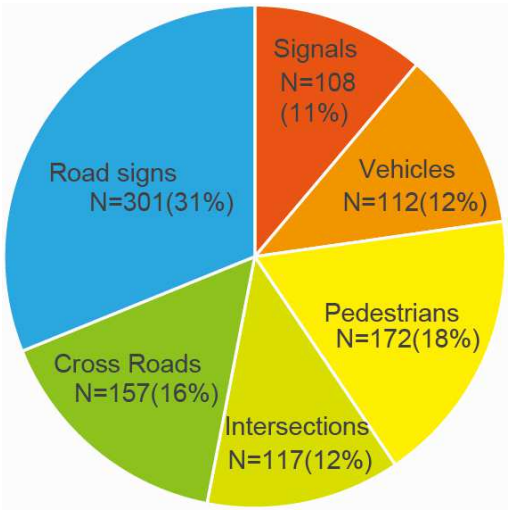

Fig. 2. Percentage of appearance of traffic objects.

appearance of the targets and the fraction of them. In this experiment, we defined the timing of appearance of the traffic objects when center of them was entered in 25% of the vertical area centered from the point at infinity. Figure 2 illustrated the percentage of the appearance of the traffic objects. In the case of the current driving scenes dataset, the fraction of each traffic target was 11%, 12%, 18%, 12%, 16%, and 31% for signals, vehicles, pedestrians, intersections, cross road, and road signs, respectively.

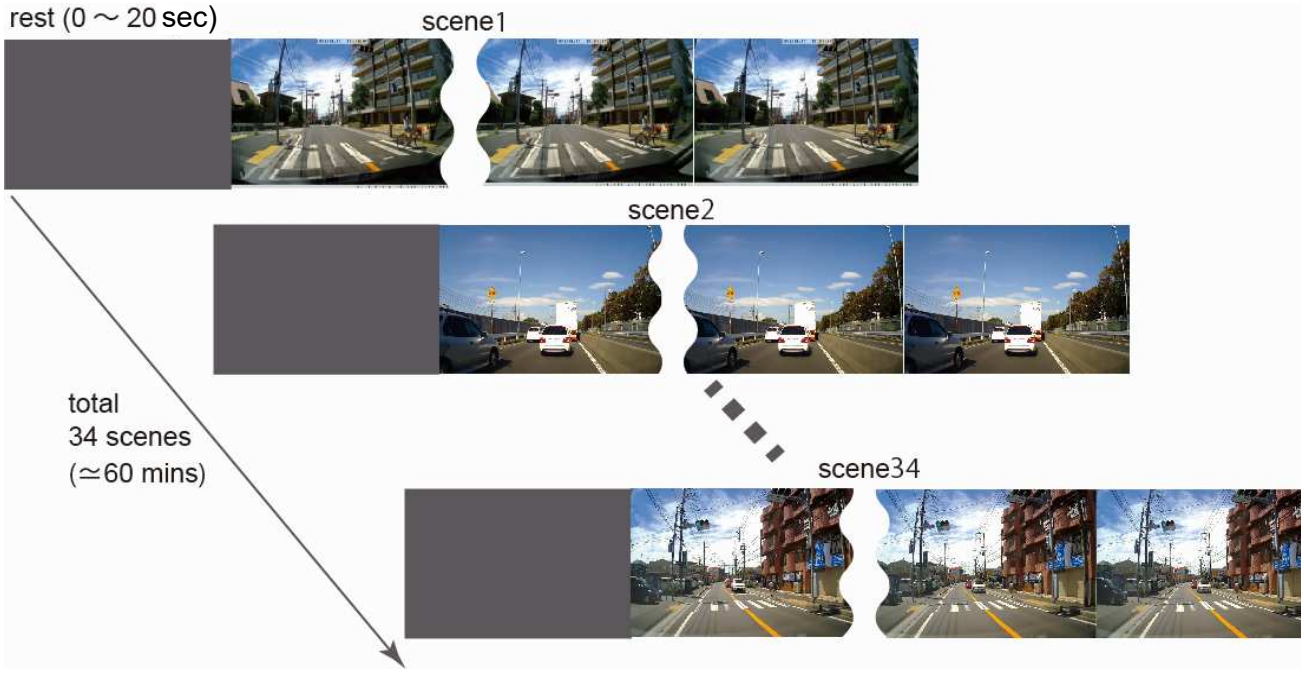

Fig. 3. Experimental stimulus and protocol. 34 traffic scenes were utilized in the experiment. Each scene consists of 20 seconds gray image for resting and traffic scenes. The duration of each traffic scene was approximately 2 minutes.

D. Experimental protocol

We first explained the experimental design to the subjects and obtained informed consent. Figure 3 summarized the stimulus of the driving scene and the experimental protocols. Each driving scene had 20 seconds of gray image for resting and the driving in the urban area with approximately 2 minutes length. These scenes were randomly projected to the PC display. We asked the subjects to watch the driving scenes and pushed the reaction button on the iPad as fast as possible when they could perceive the traffic objects. The Ethics Committee of Chubu University approved the study protocol (20210016). We performed all methods in accordance with the Declaration of Helsinki.

E. EEG recording

EEGs of all subjects were measured using Polymate Mini AP108 (Miyuki-Giken Co., Ltd.) with a 500-Hz sampling frequency. Standard scalp EEG electrodes were located in accordance with the International 10–20 System [21]. We employed 9-channel EEG at 7-electrode sites (AF3, AF4, T7, T8, Cz, O1, and O2 to cover entire brain area), and at 2-reference sites (A1 and A2).

F. Analysis

Topographic mapping of P300 event-related potential found that the P300 was dominantly distributed in the central to parietal derivations, without any left or right lateralization. Furthermore, P300 event-related potential was determined by averaging 20–30 EEG responses to the target paid attention [18]. In the present study, we focused on the EEG measured from Cz-channel.

At first, the EEG signal was filtered into the delta band (1 – 5 Hz) using a band-path filter due to that the P300 event-related potential most commonly observed in the delta band. To calculate the average response to determine P300 event-related potential, the filtered EEG between the pre- (-0.2sec) and post-appearance of the traffic target (0.8sec) was selected for each type of traffic object with adjustment of that DC level at the timing of appearance of traffic target become 0, and averaged.

Several definitions were reported to describe the P300 event-related response [18], which vary depending on stimulus modality, task conditions, and age. The EEG typically displays a peak response between 0.25 and 0.80 sec following stimulus presentation, defined as P300. In the present study, we defined the P300 event-related response as the peak response identified between 0.25 and 0.80 sec after the appearance of triggered traffic object. Note that if two peaks were observed those range, we chose second peak for the P300 event-related response to avoid choosing peak observed between N100 and N200.

III. RESULTS

We calculated the P300 event-related potential for each type of traffic object. Figure 4 summarized the P300 event-related

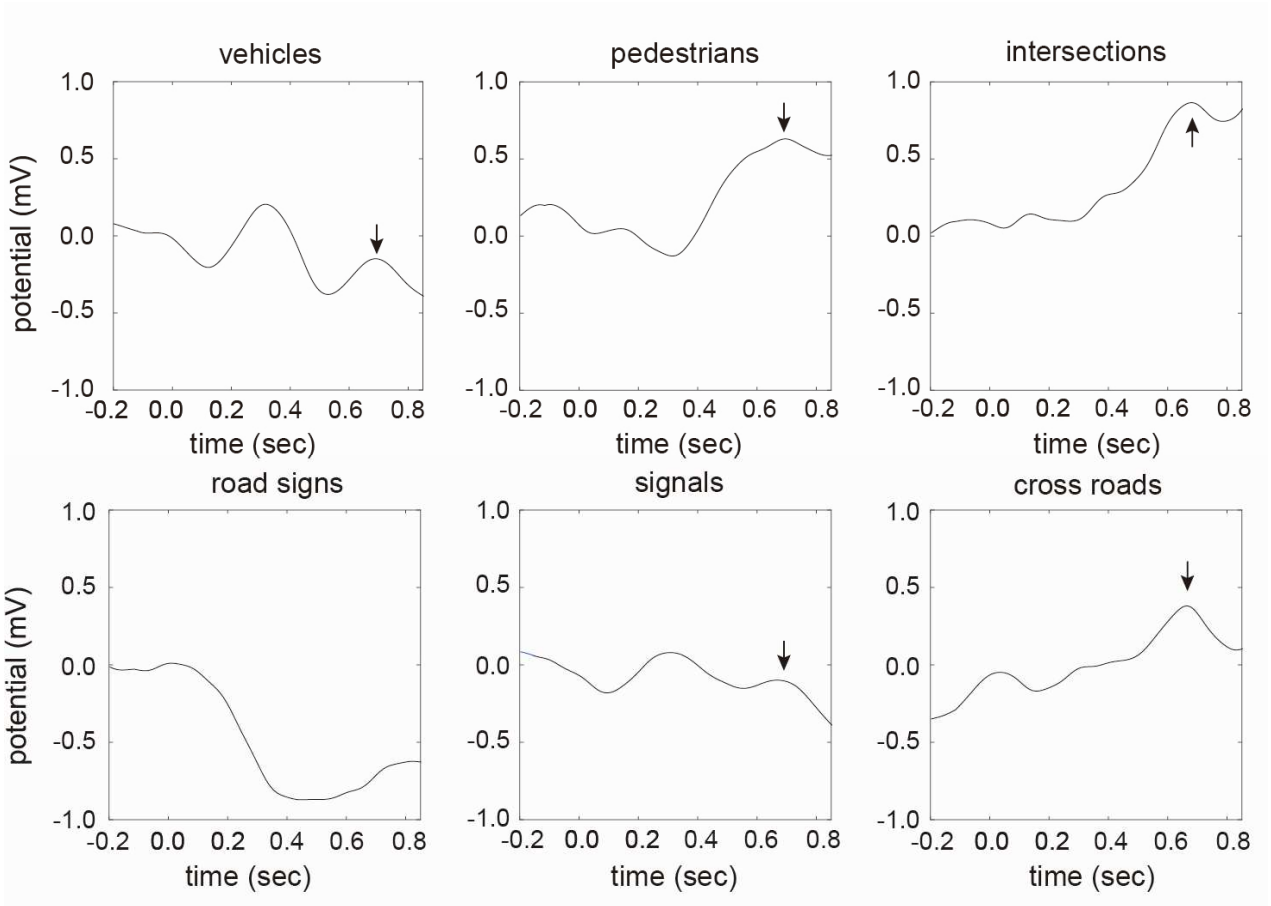

Fig. 4. Average response of P300 event-related potential for the different traffic objects. The arrow indicates P300 event-related potential.

potential for 6 different traffic object during perception of the driving scenes. For the intersection, and cross road, the P300 event-related potential with marked peak response was observed around 0.65-0.70 sec. For the vehicle, pedestrian, and signal, the P300 event-related potential response was also found around 0.65-0.70 sec; however, this response was dull (small). For the road sign, no P300 event-related potential was found.

The intensity of the attention for the traffic objects in the driving scene is different due to their characteristics such as color, luminosity, orientation, etc., and driver's experience and intention. Next, we investigated individual P300 event-related potential for the traffic objects. Table 1 showed the observation rate of P300 event-related potential for the different types of traffic objects. For the cross road and intersection, the observation rate of P300 event-related potential was, 81.8% and 81.8%, and those were relatively higher among the 6 different types of traffic objects. For the vehicle, pedestrian, and signal, the observation rate of P300 event-related potential was, respectively, 72.7%, 63.6%, and 54.5%. For the road sign, the observation rate of P300 event-related potential was 9.1%.

IV. Discussion

The present study focused on the P300 event-related potential, which is accompanied by attention, and investigated the P300 event-related potential response in visual search of multiple traffic targets. In our experimental protocol, we asked the subjects to pay attention and make a perception of traffic objects during watching driving scenes, and tap the reaction button when they perceive those traffic objects. As the results, we found that the occurrence of the P300 event-related potential in the multiple visual search depended on the types of traffic objects.

The occurrence of P300 event-related potential depended on the type of traffic object. At this point, the shapes of waveform for average response of P300 event-related potential (Figure 4) related to the observation rate of the P300 event-related potential for each type of traffic object. Namely, the clear response for P300 event-related potential appeared when the

Table. 1. Observation rate of P300 event-related potential for the different types of traffic objects

object type	P300 observation rate
vehicles	72.7% (8/11)
pedestrians	63.6% (7/11)
intersections	81.8% (9/11)
road signs	9.1% (1/11)
signals	54.5% (6/11)
cross roads	81.8% (9/11)

occurrence rate of the P300 event-related potential is high, and vice versa. Note that, even if a clear waveform of P300 event-related potential was not observed, a small number of P300 event-related potential occurred (Table1, the case of road sign).

The variability for observation of P300 event-related potential might indicate the essential ability of traffic objects to induce drivers' attention. Namely, when the ability of traffic objects to induce drivers' attention is originally high, observation of P300 event-related potential become high, and vice versa. Visual attention is a function of the brain that optimize computational resources for attention using the information from the visual field to enable us to attend to the most important current information [22] and enhance the visual perception of scenes [23]. By this process, it is revealed that the attentional shift is related to the visual saliency that is determined by visual information of the scene such as color, intensity, orientation [14-16]. In the future study, we will investigate relationship between the ability of traffic object to induce drivers' attention and characteristics of P300 event-related potential considering visual saliency of traffic objects.

V. Conclusion

We focused on the P300 event-related potential response on the traffic objects which need to make perception for the determination of appropriate driving behavior in safe driving. We found that the occurrence of P300 event-related potential response depends on the type of traffic objects. By this investigation, a part of the P300 event-related potential response for the multiple visual search could be quantified using the case of driving. In the future study, we further investigate the relationship between the ability of traffic objects to induce drivers' attention and P300 response considering the visual saliency of the traffic objects.

E-mail: akira-tamamori@aitech.ac.jp

***Abstract*—This paper proposes an extension of Random Projection Depth (RPD) to cope with multiple modalities and non-convexity on data clouds. In the framework of the proposed method, the RPD is computed in a reproducing kernel Hilbert space. With the help of kernel principal component analysis, we expect that the proposed method can cope with the above multiple modalities and non-convexity. The experimental results demonstrate that the proposed method outperforms RPD and is comparable to other existing detection models on benchmark datasets regarding Area Under the Curves (AUCs) of Receiver Operating Characteristic (ROC).**

I. Introduction

Outlier detection refers to "the problem of finding patterns in data that do not conform to expected normal behavior" [1]. Outlier detection has broad applicability and many application examples, such as fraud detection, intrusion detection, disease detection, medical diagnosis, etc. In supervised learning of classification problems, the authors have reported that utilizing outlier detection for data cleaning, i.e., removing anomalous samples as a preprocessing step, significantly improves the classification accuracy [2]. Accordingly, outlier detection is one of the important research topics in the field of data mining and machine learning.

Outlier detection algorithms often quantify the *outlyingness* (outlierness) of points on a data cloud in a multidimensional space. The opposite of outlyingness is the depth [3]. It measures the centrality of a data point, which defines how close the point is to the center of the data cloud. In other words, the depth introduces a center-outward ordering to the data cloud. Since we can construct analogs of quantiles and ranks in multidimensional datasets from the depth, many authors successfully have applied the depth function in related research fields, such as robust estimation [4], nonparametric tests [5], cluster analysis [6], discriminant analysis [7], multivariate regression [8], multivariate density estimation [9], functional data analysis [10], etc. Authors proposed various depth functions in the literature listed as follows: halfspace depth [11], simplicial volume depth [12], zonoid depth [13], spatial depth [14], projection depth [3, 15], Mahalanobis depth [3, 16], and so on. Among these depth functions, it is known that the halfspace depth and projection depth are favorable since they satisfy the desirable properties of the statistical depth [3]; affine invariance, maximality at the center, monotonicity on rays, null at infinity, etc. We also focus on the projection depth in this study because of these desirable properties. Furthermore, authors in the previous work studied an extension of the spatial depth-based outlier detection with kernel method [17]. The other study proposed an extension of Mahalanobis depth in the reproducing kernel Hilbert space [18]. Their studies are also related to ours because we consider an extension of the projection depth with the kernel method for outlier detection. In the following, we will describe our motivation in detail.

We have examined the performance of outlier detection methods based on Random Projection Outlyingness (RPO). The detection performance will degrade when data samples are not linearly separable, and the sample distribution exhibits multiple modalities. To cope with the such modalities, we have proposed the RPO-based detection method with a local score weighting [19]. However, the detection performance still needs to improve since it cannot cope with a nonlinearly separable data cloud. The RPO involves inner product computations, i.e., linear operations in the original feature space. In contrast, kernel-based detection methods such as One-Class Support Vector Machine (OCSVM) [20] can deal with such nonlinearly separable distributions using a feature map into Reproducing Kernel Hilbert Space (RKHS), and the kernel function induces the inner product in the RKHS. Combining kernel methods and projection depth will open the possibility of coping with nonlinear separability.

Given a large amount of training data available, we can use detection methods based on deep learning, such as Deep Support Vector Data Description (Deep SVDD) [21] and Deep AutoEncoding Gaussian Mixture Model [22]. These methods first perform a nonlinear mapping which maps the original features into a new feature space, and the detector is trained on the new space. Especially concerning RPO, Deep RPO [23] has been proposed; it combines Deep SVDD and RPO in the training objective. The authors demonstrated that it could improve detection performance than Deep SVDD and RPO. However, training such models on a small dataset will be challenging because sufficient data samples are only sometimes available.

This study proposes an outlier detection method based on Kernel Random Projection Depth (KRPD). A reproducing kernel function maps original feature vectors into the RKHS, and we can compute RPD on the RKHS. Although authors have proposed several methods to obtain a nonlinear mapping related to kernel approximation [24, 25], we adopt Kernel Principal Component Analysis (KPCA) to reduce the dimensionality of the feature vector. This dimensionality reduction helps make the algorithm feasible and avoids the curse of

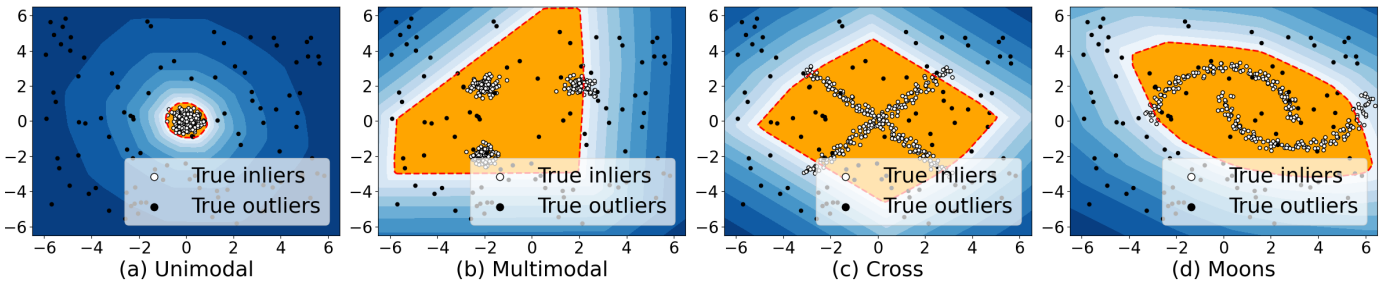

Fig. 1. Contour plots of RPD. The decision boundary is indicated by the red dot line and the central region is colored orange.

dimensionality related to the computations of an inner product in the RKHS. We conducted experiments on benchmark datasets for outlier detection. The results demonstrated that the proposed method outperformed RPD and performed better than other competitive detection methods, including OCSVM, Local Outlier Factor [26], Isolation Forest [27], and Gaussian Mixture Model [28], in terms of Area Under the Curves (AUCs) of Receiver Operating Characteristic (ROC).

II. Random Projection Depth

Suppose we are given a d-variate probability distribution P and a data cloud consisting of N data samples

$$X = \{\mathbf{x}_1, \mathbf{x}_2, \ldots, \mathbf{x}_N\}, \quad \mathbf{x}_n \sim P, \quad \mathbf{x}_n \in \mathbb{R}^d. \tag{1}$$

Random Projection Outlyingness (RPO) $O_d(\mathbf{x} \mid X)$ on X is defined as

$$O_d(\mathbf{x} \mid X) := \sup_{\mathbf{u} \in \mathbb{S}^{d-1}} \frac{|\mathbf{u}^T\mathbf{x} - \mathrm{MED}(\mathbf{u}^T X)|}{\mathrm{MAD}(\mathbf{u}^T X)}, \tag{2}$$

where $\mathbf{x} \in \mathbb{R}^d$ is a d-dimensional data point and $\mathbf{u}$ is a random unit vector drawn from the unit hypersphere $\mathbb{S}^{d-1}$. The one-dimensional, scalar-valued dataset $\mathbf{u}^T X$ is given by $\mathbf{u}^T X = \{\mathbf{u}^T\mathbf{x}_1, \mathbf{u}^T\mathbf{x}_2, \ldots, \mathbf{u}^T\mathbf{x}_N\}$. The abbreviations MED and MAD denote the median and the median absolute deviation, respectively. In accordance with the above definition, we can define Random Projection Depth (RPD) $D_d(\mathbf{x} \mid X)$ [29] as

$$D_d(\mathbf{x} \mid X) := \frac{1}{1 + O_d(\mathbf{x} \mid X)}. \tag{3}$$

Generally, the depth function is a statistic that gives a center-outward ordering to each data point $\mathbf{x}$. The point at which the depth function takes its maximum value is the median, a *deepest* point. RPD has the characteristic of not being able to deal with multimodal distributions. When we utilize RPD for outlier detection, this characteristic will likely decrease detection accuracy and robustness. To address this problem, we have proposed a method of weighting the outlyingness based on the cardinality of the clusters to which the samples belong [19]. However, this method requires the number of clusters to be determined in advance. Another characteristic of RPD is that the central region forms a convex hull, which also causes an increase in false positive errors when the data cloud is non-convex.

In order to demonstrate the above issues of RPD, we show contour plots and decision surfaces across synthetic datasets in Figure 1. In this figure, datasets are: (a) Unimodal, (b) Multimodal, (c) Cross, and (d) Moons. We generated each dataset with 400 samples (300 inliers, 100 outliers) in two-dimensional space. The true outlier samples were generated by a uniform distribution within $[-6, 6] \times [-6, 6]$. For Unimodal, the inlier samples were generated by a scaled standard normal distributions where the scale was set to 0.3. For Multimodal, the inlier samples were generated by three scaled standard normal distributions. The scale of each normal distribution was also the same value as 0.3. We generated inliers for Cross on the two vertical segments and Moons on the shifted semicircles. Small noises were added to those inliers; the strength of noise was set to 0.05 uniformly.

In this study, we utilize a negative projection depth as the outlier score; a high-depth value corresponds to an inlier, and a low-depth value corresponds to an outlier. We can identify a data point as an outlier if its outlier score is greater than a threshold [17]. The threshold was determined as 25 $(= 100 \times 100/400)$ percentile within whole predicted scores. We specify the central region as a set of points where its outlier score exceeds the threshold. The region is colored orange in the figure. We refer to the boundary of the central region as the decision boundary. The central region should include many inliers and few outliers in practice. On Unimodal, we can see that RPD successfully produces a tight boundary and the decision surface encloses almost all inliers. In this case, we can expect that outlier detection works well. However, on other datasets including Multimodal we can see that RPD fails to form tight decision boundaries to inliers and encloses inliers and many outliers. The false positive errors will increase in such cases.

III. Proposed method

We propose to compute RPD in an RKHS to resolve the issues described in the previous section, where RPD-based detection will fail on the multi-modal or not lineally separable data cloud. We refer to RPD in the RKHS as Kernel RPD (KRPD). The kernel method [30] makes the computation of KRPD feasible. In the following, we formulate the proposed method.

Suppose we are given a positive definite real-valued kernel

$$k : \Omega \times \Omega \to \mathbb{R}, \tag{4}$$

where Ω is a non-empty subset of $\mathbb{R}^d$. We refer the RKHS induced by k as $\mathcal{H}_k$ and define a feature map

$$\Phi : \Omega \to \mathcal{H}_k,\ \mathbf{x} \in \Omega \mapsto k(\cdot, \mathbf{x}). \tag{5}$$

The data cloud X is mapped to the data cloud $\mathcal{F}_k(X)$ on $\mathcal{H}_k$:

$$\mathcal{F}_k(X) = \{\Phi(\mathbf{x}_1), \Phi(\mathbf{x}_2), \ldots, \Phi(\mathbf{x}_N)\} \subset \mathcal{H}_k. \tag{6}$$

We can define the outlyingness $O_k(\mathbf{x} \mid \mathcal{F}_k(X))$ and the projection depth $\mathcal{D}_k(\mathbf{x} \mid \mathcal{F}_k(X))$ on $\mathcal{H}_k$ sequentially as

$$O_k(\mathbf{x} \mid \mathcal{F}_k(X)) \coloneqq \sup_{\|f\|=1} \frac{|\langle f, \Phi(\mathbf{x})\rangle - \mathrm{MED}(\langle f, \mathcal{F}_k(X)\rangle)|}{\mathrm{MAD}(\langle f, \mathcal{F}_k(X)\rangle)}, \tag{7}$$

and

$$\mathcal{D}_k(\mathbf{x} \mid \mathcal{F}_k(X)) \coloneqq \frac{1}{1 + O_k(\mathbf{x} \mid \mathcal{F}_k(X))}, \tag{8}$$

where $\|\cdot\|$ denotes the norm in $\mathcal{H}_k$. The $\langle f, \mathcal{F}_k(X)\rangle$ is an abbreviation of the scalar-valued data cloud

$$\langle f, \mathcal{F}_k(X)\rangle = \{\langle f, \Phi(\mathbf{x}_1)\rangle, \langle f, \Phi(\mathbf{x}_2)\rangle, \ldots, \langle f, \Phi(\mathbf{x}_N)\rangle\}, \tag{9}$$

where $\langle \cdot, \cdot \rangle$ denotes the inner product of $\mathcal{H}_k$. Through nonlinear kernel function k and its feature map, we expect that the projection depth is robust to the distribution with multi modality and non-convexity.

Since the dimensionality of $\mathcal{H}_k$ is not necessarily finite, the unit sphere $\mathcal{S}_k = \{f \in \mathcal{H}_k \mid \|f\| = 1\}$ is generally not a compact set. This leads to the case that the supremum of Eq.(7) cannot be approximated through a sequence of elements in $\mathcal{S}_k$ and the computation of the projection depth becomes infeasible. To derive the computationally feasible algorithm, we resort to the representer theorem [30]. We can assume that an element $f \in \mathcal{S}_k$ belongs to the linear span of $\mathcal{F}_k(X)$:

$$f = \sum_{n=1}^{N} \alpha_n \Phi(\mathbf{x}_n) = \sum_{n=1}^{N} \alpha_n k(\cdot, \mathbf{x}_n), \tag{10}$$

where $(\alpha_1, \alpha_2, \ldots, \alpha_N) \in \mathbb{R}^N$. The condition $\|f\| = 1$ can be rewritten as

$$\boldsymbol{\alpha}^T \mathbf{K} \boldsymbol{\alpha} = 1, \tag{11}$$

where $\boldsymbol{\alpha} = (\alpha_1, \alpha_2, \ldots, \alpha_N)^T$ and $\mathbf{K}$ is the $N \times N$ Gram matrix:

$$\mathbf{K} = \begin{pmatrix} k(\mathbf{x}_1, \mathbf{x}_1) & k(\mathbf{x}_1, \mathbf{x}_2) & \cdots & k(\mathbf{x}_1, \mathbf{x}_N) \\ k(\mathbf{x}_2, \mathbf{x}_1) & k(\mathbf{x}_2, \mathbf{x}_2) & \cdots & k(\mathbf{x}_2, \mathbf{x}_N) \\ \vdots & \vdots & \ddots & \vdots \\ k(\mathbf{x}_N, \mathbf{x}_1) & k(\mathbf{x}_N, \mathbf{x}_2) & \cdots & k(\mathbf{x}_N, \mathbf{x}_N) \end{pmatrix}. \tag{12}$$

We can indeed compute the projection depth approximately in $\mathcal{H}_k$ by sampling $\boldsymbol{\alpha}$ from the hyperellipsoid of $\boldsymbol{\alpha}^T \mathbf{K} \boldsymbol{\alpha} = 1$. However, the inner product between high dimensional vectors suffers from the curse of dimensionality; almost all vectors in a high dimensional space are orthogonal to each other [31, 32]. This characteristic will significantly reduce the efficiency and accuracy of depth computation. To improve the efficiency and accuracy, we propose to perform a dimensionality reduction by KPCA [33] before computing projection depth. In this paper, we denote the principal dominant components as $\boldsymbol{\beta}$ for a data point $\mathbf{x}$ and its dimensionality as M. We also denote the new data cloud as $F(X) = \{\boldsymbol{\beta}_1, \boldsymbol{\beta}_2, \ldots, \boldsymbol{\beta}_N\}$. By treating $\boldsymbol{\beta}$ and $\boldsymbol{\beta}_n$ as new coordinates in $\mathbb{R}^M$, the projection depth can be computed in the same manner as in $\mathbb{R}^M$. If setting $M < N$, we can simultaneously achieve a nonlinear dimensionality reduction and a feasible computation of the projection depth. The overall computation algorithm is summarized in Algorithm 1. In the step 5), the projected data cloud $\mathbf{u}_l^T F(X)$ is defined as $\mathbf{u}_l^T F(X) \coloneqq \{\mathbf{u}_l^T \boldsymbol{\beta}_1, \mathbf{u}_l^T \boldsymbol{\beta}_2, \ldots, \mathbf{u}_l^T \boldsymbol{\beta}_N^T\}$. The projection depth $\mathcal{D}_k(\mathbf{x} \mid \mathcal{F}_k(X))$ is approximated as

$$\mathcal{D}_k(\mathbf{x} \mid \mathcal{F}_k(X)) \approx D_M(\boldsymbol{\beta} \mid F(X)) \tag{13}$$

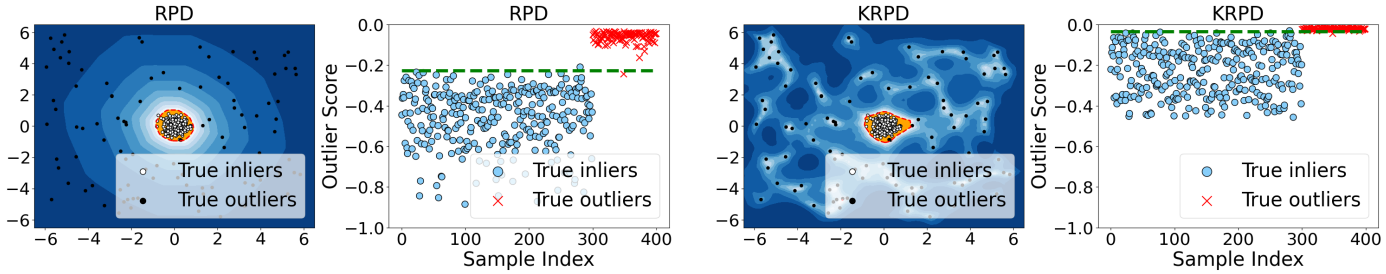
$$\approx \left(1 + \max_{1 \le l \le L} \frac{|\mathbf{u}_l^T \boldsymbol{\beta} - \mathrm{MED}(\mathbf{u}_l^T F(X))|}{\mathrm{MAD}(\mathbf{u}_l^T F(X))}\right)^{-1}. \tag{14}$$

We also utilize a negative projection depth as the outlier score in the same way as RPD. The outlier detection algorithm is also the same.

Algorithm 1 Computation of outlier score based on KRPD.

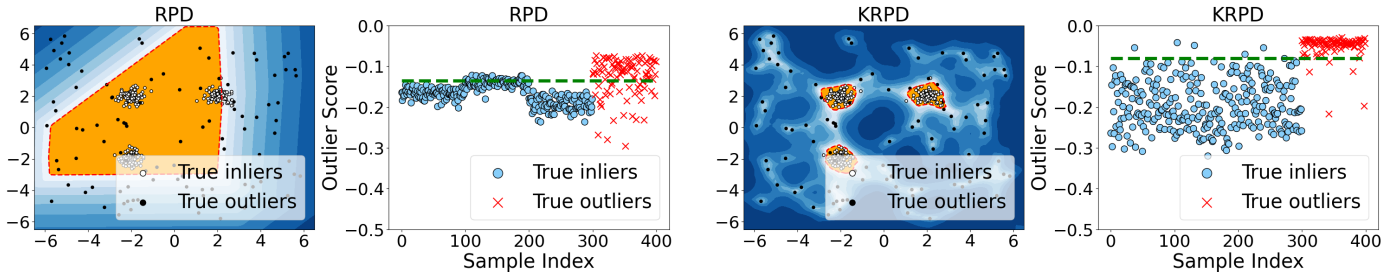
Input: Data cloud $X = \{\mathbf{x}_1, \mathbf{x}_2, \ldots, \mathbf{x}_N\} \subset \Omega$, kernel function k, dominant dimensionality M, the number of random projection vectors L, and a data point $\mathbf{x} \in \Omega$.

Output: Negative projection depth $-D_M(\boldsymbol{\beta} \mid F(X))$.



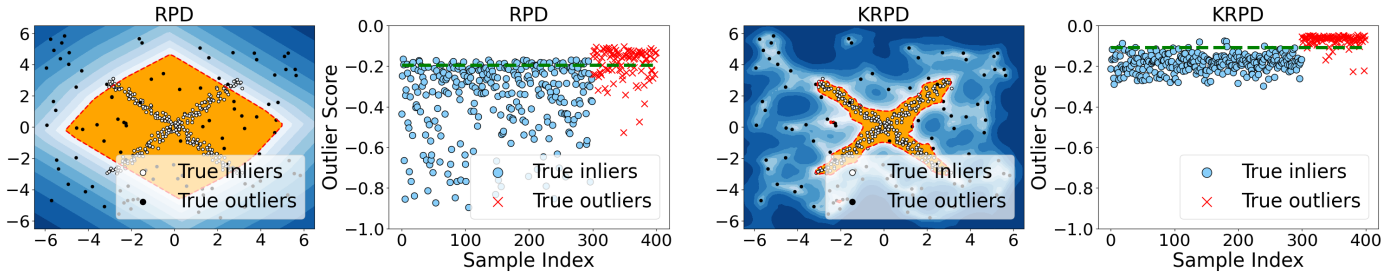
1: Compute the Gram matrix $\mathbf{K}$ between $\mathbf{x}$ and X, and obtain the centralized matrix $\mathbf{K}'$ from $\mathbf{K}$ [30].
2: Compute principal components $\boldsymbol{\beta}_n \in \mathbb{R}^M$ for each $\mathbf{x}_n$ by solving the eigenvalue problem of $\mathbf{K}'$, and obtain the new data cloud: $F(X) = \{\boldsymbol{\beta}_1, \boldsymbol{\beta}_2, \ldots, \boldsymbol{\beta}_N\}$.
3: Draw a set of L random unit vectors from the unit hypersphere $\mathbb{S}^{M-1}$: $U = \{\mathbf{u}_1, \mathbf{u}_2 \ldots, \mathbf{u}_L\} \subset \mathbb{S}^{M-1}$.
4: Compute the principal component $\boldsymbol{\beta} \in \mathbb{R}^M$ for $\mathbf{x}$.
5: Compute the projected data cloud $\mathbf{u}_l^T F(X)$ for $1 \le l \le L$.
6: **return** $-D_M(\boldsymbol{\beta} \mid F(X))$ in accordance with Eq. (14).

IV. Experimental Evaluation

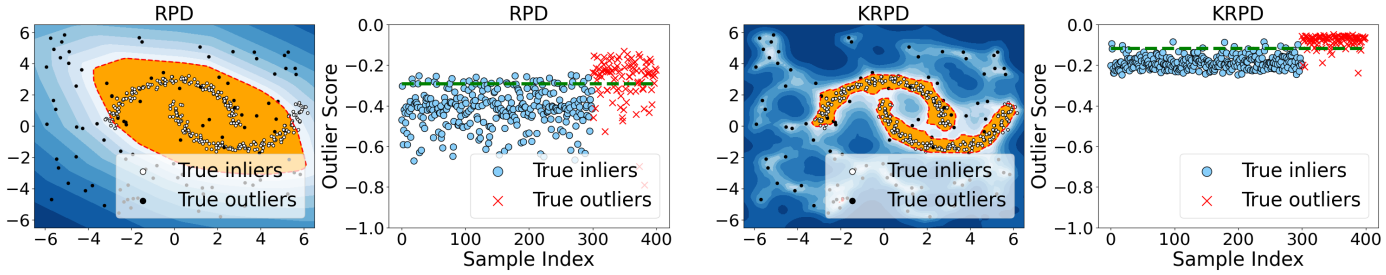


We conducted experiments on toy example data and benchmark datasets to evaluate the detection performance of proposed model. The following detection methods were compared with KRPD:

- k-Nearest Neighbors (kNN) [34]
- Local Outlier Factor (LOF) [26]
- Isolation Forest (IForest) [27]
- One-Class Support Vector Machine (OCSVM) [20]
- Kernel Principal Component Analysis (KPCA) [35]
- Random Projection Depth (RPD) [29]



In this study, RBF kernel function $k(\mathbf{x}, \mathbf{y}) = \exp(-\gamma ||\mathbf{x} - \mathbf{y}||^2)$ was used for OCSVM, KPCA and KRPD.



(a) Unimodal

(b) Multimodal

(c) Cross

(d) Moons

Fig. 2. Contour plots and outlier score comparison between RPD and KRPD. The threshold is indicated by the green dotted line in the outlier score plot. High outlier score corresponds to strong outlyingness.

A. Toy Example

Figure 2 shows contour plot comparisons between RPD and KRPD across toy datasets. We used the same datasets as in Figure 1. We fixed the kernel parameter γ and the dominant dimensionality M to 0.25 and 100, respectively. The threshold of the central region was determined according to the ratio of inliers to the total samples. Namely, the 75 ($= 100 \times 300/400$) percentile of the outlier scores. We also show the outlier scores on each toy data dataset. In these figures, the central region is colored orange and the threshold is represented as the green dotted line. First, we can see that the decision boundaries of both RPD and KRPD could enclose inliers on the unimodal. It is apparent that the corresponding scores are separated well, and consequently, we obtain few detection errors. Compared with RPD, we can see that the decision boundary of KRPD successfully encloses almost all inlier samples, and many outliers are outside the central region even when the data cloud exhibits multiple modalities and non-convexity. On the multimodal, scores of RPD from several inliers exceed the threshold. Such exceeded scores lead to an increase in false negative detection errors. Furthermore, many scores of RPD from outliers are lower than the threshold, which leads to an increase in false positive errors. In contrast, both false positive/negative detection errors decrease in KRPD, as we can

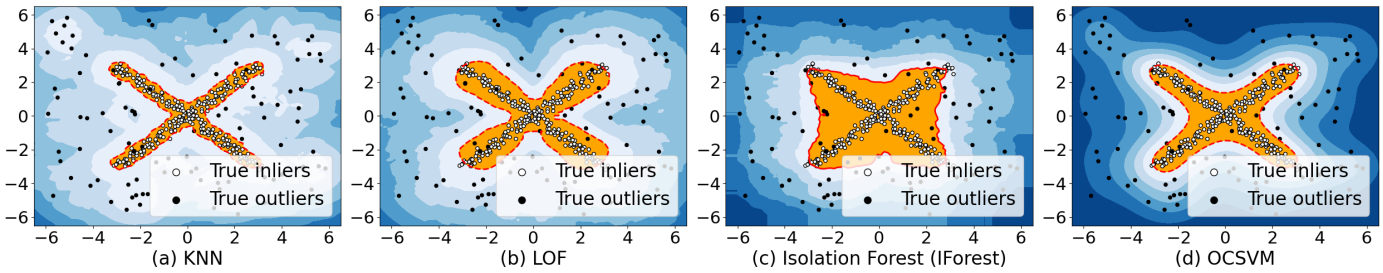


Fig. 3. Contour plots of detection methods on the Cross dataset.

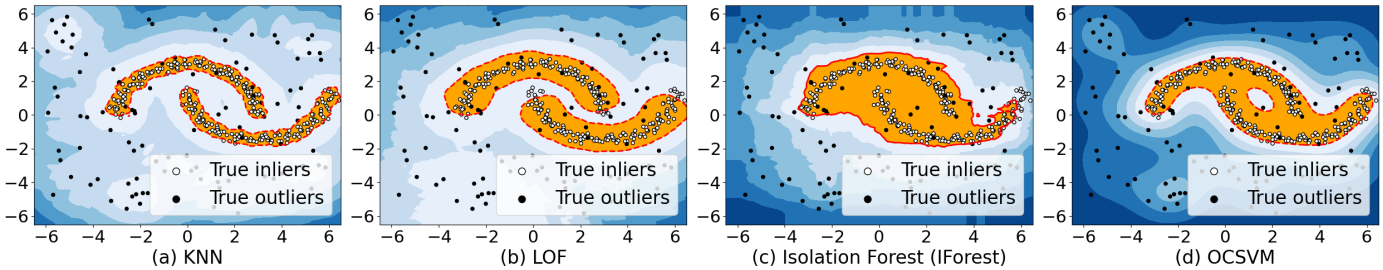

Fig. 4. Contour plots of detection methods on the Moon dataset.

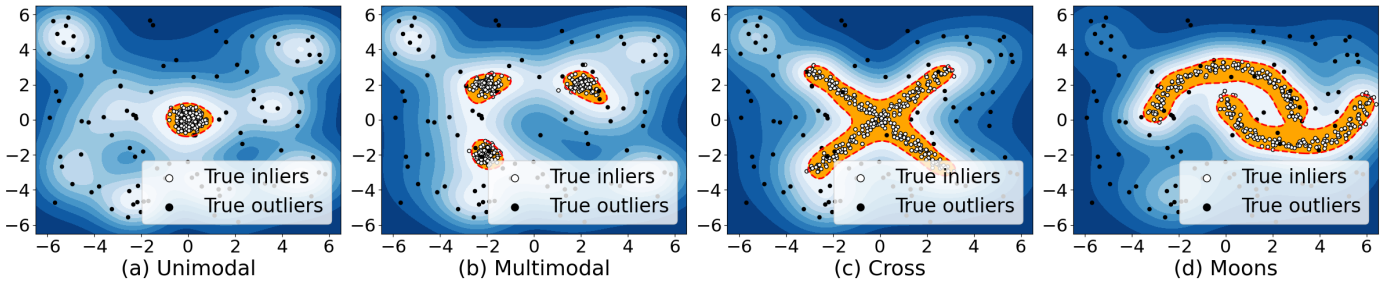

Fig. 5. Contour plots of KPCA-based detector on the toy datasets.

see from the right side of the figure. The trend is also generally true for the remaining Cross and Moons. From these results, we can expect that KRPD will demonstrate better detection performance than RPD.

Figure 3 and 4 show the contour plot comparisons on the Cross and Moons dataset, respectively. We can see that the decision boundary of IForest circumscribed the dataset and failed to capture the modalities, which led to an increase in false positive errors. kNN, LOF, and OCSVM achieved tighter boundaries to capture the modalities. Figure 5 shows the contour plots of KPCA on the toy datasets. We applied the same RBF kernel and the hyperparameter γ for both KPCA and KRPD. The dominant dimensionality M was set to 10 for KPCA. In the KPCA-based detection, we used the reconstruction error in the feature space as the outlier score [35]. From the figure, we can see that the boundary fitted the data cloud tightly, and even only KPCA obtained favorable feature spaces for outlier detection. Comparing with these figures and Figure 2, we consider that KRPD could achieve the competitive decision boundaries to other methods.

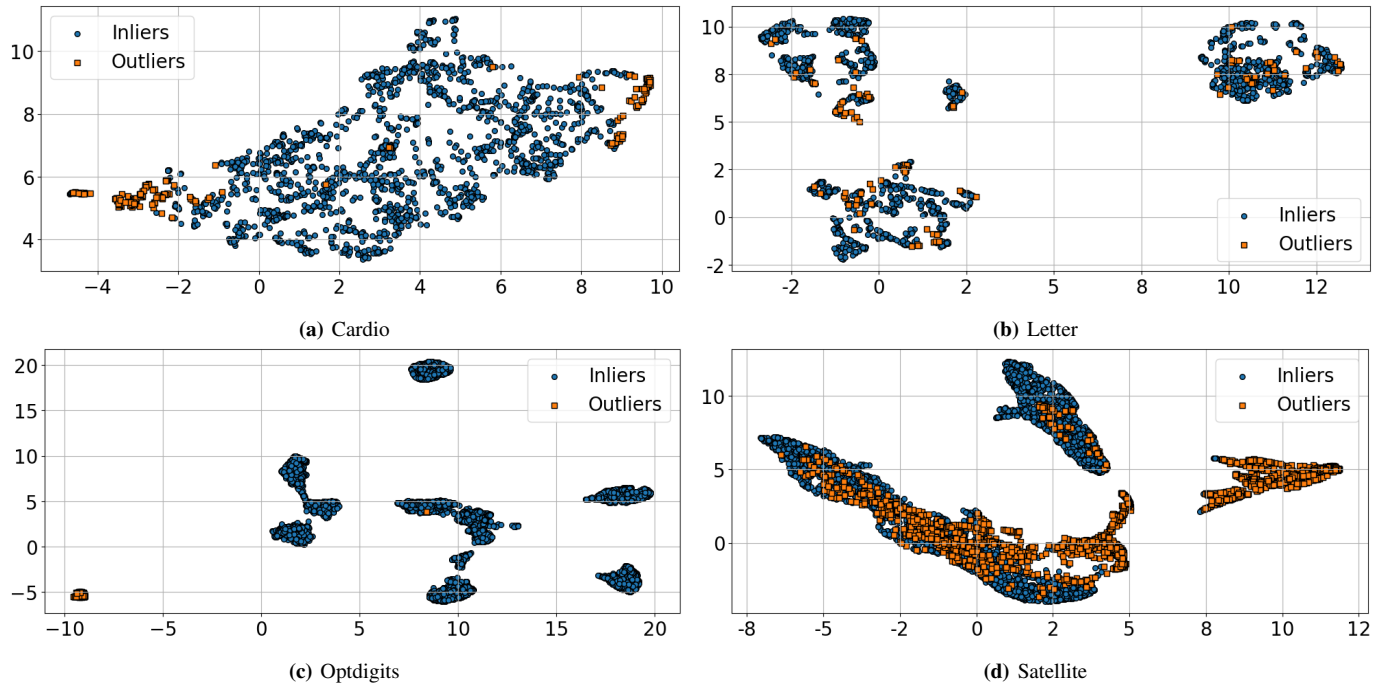
We randomly split each dataset into training and test data in a stratified fashion, specifying a seed; 60% for training and 40% for testing. The outlier percentage was kept the same on both training and test because of the stratified fashion. This split scheme intends to simulate data contamination and evaluate the robustness of the existence of outliers. Moreover, we performed a 5-fold stratified cross-validation on the training data for hyperparameter search. In each fold, 80% of training data were used for actual model training, and the rest of 20% were used for validation.

For both RPD and KRPD, the number of axes L for random projections was fixed to 1000. In order to optimize other hyperparameters, we utilized a framework using the Optuna package [37], which implements a Bayesian optimization. In this framework, we selected a strategy to maximize the ROC AUCs. For OCSVM, KPCA and KRPD, the kernel parameter γ was optimized between $[0.00001, 1.0]$. For both KPCA and KRPD, the number of principal components M was optimized between $[10, 500]$. We can obtain the label information as binary ones because the training data contains inliers and outliers. Hence we could also compute ROC AUCs on each fold of the training data, and the hyperparameters were determined semi-supervised. The Optuna optimized the hyperparameters according to the maximization criterion.

Table II lists ROC AUCs. We can see that KRPD outperformed RPD regarding ROC-AUCs on the nine datasets. Significantly, KRPD greatly improved the detection performance on Letter and Optdigits datasets. On the three datasets of Cardio, Musk, and Satimage-2, the performance of RPD was almost the same as KRPD. The averaged AUCs of KPCA was 0.864 ± 0.022, and it was comparable to other detection methods. Although KPCA outperformed KRPD on several datasets, KRPD outperformed KPCA on average, and especially, the improvement was significant on the Optdigits.

V. DISCUSSION



We have shown in the previous section that KRPD outperformed RPD and was comparable to other detection methods on average. These results demonstrate the effectiveness of KRPD in detecting outliers. However, KRPD did not deliver the best detection performance across all datasets. In this section, we will consider why we obtained variations across datasets in the detection performance of KRPD by using a visualization of datasets. We will also clarify the advantages against other methods and limitations of KRPD.

A. Variations of detection performance across datasets

Figure 6 shows visualizations of Cardio, Letter, Optdigits, and Satellite datasets by UMAP [38]. As shown in Figure 6a of Cardio, almost outliers locate around the edge of the inlier distribution, and the distribution looks roughly uni-modal. This observation explains why RPD outperformed KRPD slightly. Next, on Letter and Optdigits, KRPD outperformed RPD significantly. From the corresponding visualization of Letter as shown in Figure 6b, we can observe that roughly three clusters exist, corresponding to three capital letters in the English alphabet. Those clusters are further split into many small groups, and outliers are scattered. The detection with KRPD worked well even in such a challenging dataset. The Optdigits is a collection of instances of digits 0-9, and digit 0 is the outlier class. We can observe that its data cloud of Optdigits forms explicit clusters corresponding to each digit, and hence it shows multiple modalities. These observations also explain the superior performance of KRPD to RPD and other methods. As shown in Figure 6d of Satellite, the data cloud of outliers overlaps that of inliers, partly explaining the decrease of AUCs for KRPD. Namely, this decrease explains that KRPD is sensitive to the existence of outliers, that is, contamination in the training data, leading to an increase in the false alarm rate.

B. Detection performance without KPCA

As described in Section III, KPCA is applied to avoid reducing the efficiency and accuracy of depth computation. Hence, a natural question arises: How much will the performance degrade without KPCA? We conducted additional experiments to investigate the impact of using or not using KPCA on detection performance. We selected a kernel approximation method with random Fourier features (RFF) [24]. The RFF obtains a high dimensional vector for each $\mathbf{x}_n$ in the data

TABLE III
ROC AUC SCORES OF KRPD W/O AND W/ KPCA. AVERAGE OF 5 INDEPENDENT TRIALS IS SHOWN. THE BETTER METHOD IS INDICATED IN **BOLD**.

Dataset	w/o KPCA (RFF)	w/ KPCA
Arrhythmia	0.768 ± 0.033	**0.791 ± 0.026**
Cardio	**0.943 ± 0.015**	0.926 ± 0.015
Ionosphere	0.855 ± 0.039	**0.935 ± 0.012**
Letter	0.618 ± 0.018	**0.865 ± 0.018**
MNIST	0.820 ± 0.033	**0.856 ± 0.006**
Musk	**0.998 ± 0.002**	0.997 ± 0.005
Optdigits	0.543 ± 0.043	**0.755 ± 0.070**
Pendigits	0.896 ± 0.020	**0.920 ± 0.008**
Satellite	0.689 ± 0.020	**0.727 ± 0.005**
Satimage-2	**0.996 ± 0.003**	0.994 ± 0.006
Vowels	0.787 ± 0.035	**0.905 ± 0.021**
Wbc	0.896 ± 0.030	**0.906 ± 0.012**
Average	0.817 ± 0.025	**0.882 ± 0.017**

cloud X, and hence we can compute the projection depth. The number of Monte Carlo samples for RFF, corresponding to the dimensionality of the feature vector, was optimized between $[10, 500]$ with the Optuna package. The kernel parameter was also optimized between $[0.00001, 1.0]$.

Table III lists the ROC AUCs of KRPD without and with KPCA. We can see that the average performance significantly decreased without KPCA. We consider that this performance degradation was due to the curse of dimensionality because RFF involves computations of the inner product in a high dimensional space to approximate the kernel function. As described in Section III, almost all pairs of vectors on a unit hypersphere will become orthogonal. This fact significantly affects the computation of projection depth and partly explains the performance degradation without KPCA.

C. Limitations and future work

Since KRPD inherits advantages from KPCA, it also inherits its limitations. First, careful hyperparameter tuning is often required. In the experimental evaluation, the KRPD hyperparameters could be determined semi-supervised since we had labeled samples available. KRPD will be more effective in semi-supervised situations. Second, KPCA is not necessarily robust to outliers in the training data. Although KPCA has an application of denoising [39], its formulation does not assume the existence of outliers, and the outliers will distort the direction of eigenvectors. Authors in the previous study [40] have proposed several regularization techniques to obtain eigenvectors robustly against outliers. In the future, we will consider an extension of KPCA for RPD to cope with outliers and robust extraction of eigenvectors. Third, the computational complexity is still $O(N^3)$, where N is the number of training samples. Approximate kernel PCA [41] will be effective when N itself becomes a large number, e.g., $N > 10^4$. Kernel PCA with an online learning algorithm [42] will also reduce computational complexity. We will investigate correlations among the number of training samples, the dimensionality of the principal subspace, and its detection performance. Lastly, we have not given statistical support to explain the improved detection performance from the viewpoint of statistical depth. We are interested in how the desirable properties of statistical depth [3] behave when changing the dimensionality M and the number of training samples N.

VI. Conclusion

In this paper, we proposed KRPD, an extension of RPD for outlier detection. The original data cloud is mapped to RKHS by a reproducing kernel function, and we can compute RPD in the RKHS. With the help of KPCA, the decision boundary of KRPD fits the data cloud tightly even when the cloud shows complicated multiple modalities and non-convexity. We evaluated outlier detection performance for RPD, KRPD, and other popular methods on 12 benchmark datasets. The experimental results demonstrated that KRPD outperformed RPD and was comparable to other methods. We also discussed the detection performance between KPCA and KRPD and confirmed that KRPD was more effective than KPCA. We plan to extend KRPD further to utilize robust KPCA.

Soft-Sensor Construction Method Based on Adaptive Modeling and Transfer Learning for Manufacturing Process Including Maintenance Periods

Kaito Katayama* and Koichi Fujiwara * and Kazuki Yamamoto †

***Abstract*—Various soft-sensor construction methods based on transfer learning have been proposed to quickly adapt soft-sensors to changes in process characteristics caused by process maintenance. However, most of the conventional methods adopt transfer learning immediately after the maintenance. Since process characteristics may also change due to other than process maintenance, it is necessary for the conventional methods to switch to a soft-sensor that is applicable to the current process characteristics at the appropriate time; however, it is difficult to properly determine the switching timings of soft-sensors. This study proposes a new adaptive soft-sensor construction method called Latest Sample Targeting Frustratingly Easy Domain Adaptation (LST-FEDA) based on adaptive modeling and FEDA which is a kind of transfer learning method. In the proposed LST-FEDA, the application range of FEDA is updated and rebuilds a soft-sensor when a new query sample is measured. This approach enables soft-sensors to automatically adapt to changes in process characteristics without intentional soft-sensor switching.**

In order to demonstrate the effectiveness of the proposed LST-FEDA, it was applied to actual operation data of a distillation process including maintenance periods. The results demonstrated that LST-FEDA improved the RMSE by 19% on average in comparison with the conventional methods.

I. Introduction

In manufacturing processes, product quality or other important variables are often measured through offline analysis at regular intervals. Because offline analysis is burdensome and time-consuming, there is a risk of producing off-spec products between analysis intervals. Quality management using soft-sensors that predict product quality from process variables measured on-line has been widely used. However, there is a possibility that the prediction performance of soft-sensors deteriorates when the process characteristics change due to process maintenance or aging. Thus, it is essential to adapt soft-sensors to changes in process characteristics for stable and efficient process operation.

To deal with such changes and to update soft-sensors automatically, adaptive modeling methods, such as Moving Window (MW) modeling [1] and Just-in-Time (JIT) modeling [2], have been developed. In addition, soft-sensor construction methods based on transfer learning have been developed [3], [4], [5]. These methods enable soft-sensors to adapt quickly to changes in process characteristics due to process maintenance or aging. In transfer learning, the domain that transfers information is called the source domain (D^S) and the domain that receives information from the source domain is called the target domain (D^T) data.

Ye *et al.* proposed a method for training Online Sequential Extreme Learning Machines with Kernels (OS-ELMK) to utilize knowledge from old data for future forecasts using transition learning. The method was shown to provide highly accurate forecasts for various types of time series forecasting problems [4]. Lie *et al.* proposed a soft sensing method which transfers process information between different operating grades to construct soft-sensors for multi-grade chemical processes. Their proposed method, Domain Adaptation Extreme Learning Machines (DAELM), can construct high-performance soft-sensors even with limited supervised data [5]. As a simpler method of applying transition learning, Yamada *et al.* proposed a soft-sensor construction method combining an adaptive modeling method and a transfer learning method called Frustratingly Easy Domain Adaptation (FEDA) [6] for chemical processes that produce products with grade switching [7]. They used the method for transfering the process data from various grades to the process data of the target grade, and predicted the product quality shortly after grade switching. Their proposed method achieved a high prediction performance of product quality even after grade switching.

Transfer learning enables accurate predictions in processes with significant changes in operating conditions. However, when transfer learning is applied to adaptive soft-sensors, the similarity between the target domain and source domain may become low when an excessive amount of target domain samples are stored, which may lead to improper information transference [7]. If improper information is transferred, negative transfer may occur and degrade the prediction performance compared with even when transfer learning is not used [8]. In addition, when negative transfer occurs, the continued application of transfer learning has the potential to permanently deteriorate the prediction performance of the soft-sensors. Although most of the conventional methods using transfer learning are required to switch soft-sensors when a certain number of target domain samples were stored, it is often difficult to determine the appropriate timing for switching accurately.

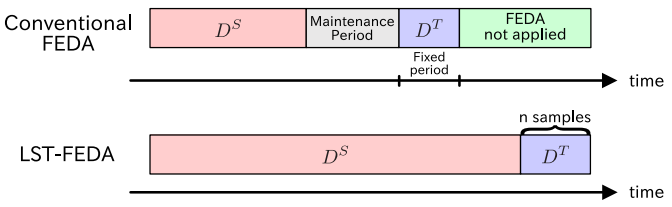

Fig. 1. Domain definitions of conventional FEDA and LST-FEDA

In this study, we propose a new adaptive soft-sensor construction method based on adaptive modeling and FEDA, called Latest Sample Targeting FEDA (LST-FEDA). In the proposed LST-FEDA, the specific number of samples in training data temporally close to a query sample are defined as the target domain. Whenever a new training sample is measured, the definition of the target domain is updated in a first-in-first-out manner and soft-sensors are rebuilt. In the proposed method, there is no need to switch soft-sensors to prevent negative transfer because it can keep the number of samples in the target domain constant.

We report application results of LST-FEDA to the actual operation data of a distillation process including process maintenance.

II. Methods

A. Frustratingly Easy Domain Adaptation

FEDA is a kind of transfer learning method that simply extends a feature space. When the source domain data $\boldsymbol{X}_S \in \mathbb{R}^{N_S \times M}$ and the target domain data $\boldsymbol{X}_T \in \mathbb{R}^{N_T \times M}$ are given, the new data $\boldsymbol{\Phi}(\boldsymbol{X}) \in \mathbb{R}^{(N_S+N_T)\times 3M}$ are constructed as follows:

$$\boldsymbol{\Phi}(\boldsymbol{X}) = \begin{bmatrix} \boldsymbol{X}_S & \boldsymbol{X}_S & \boldsymbol{0} \\ \boldsymbol{X}_T & \boldsymbol{0} & \boldsymbol{X}_T \end{bmatrix} \tag{1}$$

Where N_S and N_T are the numbers of samples in the source and target domain, respectively; and M is the number of variables in $\boldsymbol{X}_S$ and $\boldsymbol{X}_T$ [6].

The common information between the source domain and the target domain can be modeled from $\boldsymbol{X}_S$ and $\boldsymbol{X}_T$. In addition, specific information in the source domain is modeled from $\boldsymbol{X}_S$ and $\boldsymbol{0}$, and specific information in the target domain is from $\boldsymbol{0}$ and $\boldsymbol{X}_T$ [7]. Thus, FEDA can construct models considering common and specific information of each domain by using (1).

B. Latest Sample Targeting FEDA

In this study, we propose a new adaptive soft-sensor construction method called Latest Sample Targeting FEDA (LST-FEDA), which defines only the latest n samples as the target domain, as shown in Fig. 1. The proposed method can prevent negative transfer caused by excessive sample storage in the target domain data and enables the continuous application of FEDA.

Among the input data $\boldsymbol{X} \in \mathbb{R}^{N\times M}$, the n temporally closest samples to the query sample $\boldsymbol{x}_q \in \mathbb{R}^M$ are defined as the target domain data $\boldsymbol{X}_{new} \in \mathbb{R}^{n\times M}$ and the past data before $\boldsymbol{X}_{new}$ are defined as the source domain data $\boldsymbol{X}_{past} \in \mathbb{R}^{(N-n)\times M}$. $\boldsymbol{X}$ and $\boldsymbol{x}_q$ are extended based on (1), and soft-sensors are constructed with the extended data $\boldsymbol{\Phi}(\boldsymbol{X}) \in \mathbb{R}^{N\times 3M}$ and $\boldsymbol{\Phi}(\boldsymbol{x}_q) \in \mathbb{R}^{3M}$ as follows:

$$\boldsymbol{\Phi}(\boldsymbol{X}) = \begin{bmatrix} \boldsymbol{X}_{past} & \boldsymbol{X}_{past} & \boldsymbol{0} \\ \boldsymbol{X}_{new} & \boldsymbol{0} & \boldsymbol{X}_{new} \end{bmatrix} \tag{2}$$

$$\boldsymbol{\Phi}(\boldsymbol{x}_q) = \begin{bmatrix} \boldsymbol{x}_q^\top & \boldsymbol{0}^\top & \boldsymbol{x}_q^\top \end{bmatrix}^\top \tag{3}$$

When a new input sample is measured, the new sample is added to $\boldsymbol{X}_{new}$ and the oldest sample in $\boldsymbol{X}_{new}$ is moved to $\boldsymbol{X}_{past}$ to keep the number of samples in $\boldsymbol{X}_{new}$ constant in a first-in-first-out manner.

III. Case Study

A. Distillation process

In this study, we analyzed the actual operation data of the distillation process of a fluorinated telomer intermediate including maintenance periods, provided by AGC Inc, in Japan. The operation data consist of 21 process variables listed in Table I, and the objective quality variable of the telomer intermediate was analyzed using gas chromatography. Fig. 2 illustrates a flow diagram of the distillation process, and the numbers in Fig. 2 indicate the corresponding measurement sensors of the process variables in Table I. The process variables were measured every ten minutes, and the quality variable was analyzed approximately two or three times a day. The process is shut down due to maintenance from February to March every year. Thus, the data during the maintenance periods are lost.

In this study, we used the operation data measured from May 2020 to October 2022. The training data were from 2020 and 2021, and the test data were from 2022. The dataset for constructing soft-sensors used process variables 10, 20, and 30 minutes before the sampling time of the quality variable in addition to the process variables at the same time as the quality variable measurement in order to consider process dynamics. The purity of the telomer intermediate was the objective quality variable predicted by soft-sensors.

B. Comparison methods

To verify the effectiveness of the proposed LST-FEDA, we compared it with the following two methods:

1) Not Applied: Construct adaptive soft-sensors without FEDA.
2) Conventional FEDA: Constructs adaptive soft-sensors by applying FEDA over a period of one month after process maintenance. The process data before maintenance are the source domain and the data after maintenance are the target domain. In other periods, soft-sensors were constructed without FEDA.

Note that the period of application of FEDA in Conventional FEDA was set to the period when the influence of maintenance

was considered to be strongly present based on the opinions of the employees of AGC Inc.

C. Results

In the practical stage, the soft-sensors were reconstructed each objective variable measurement so that it adapts to the current process state. To evaluate the performance of the soft-sensors in the same situation, the soft-sensors of this study were constructed only for next sample prediction. After prediction, the sample was added to the training data and utilized for the next soft-sensor construction. we continued to update the soft-sensors in this way and calculated the prediction performance of each soft-sensor based on the prediction results for the samples considered as test data. In this study, we tried two types of soft-sensor construction methods: MWPLS and LWPLS. MWPLS is combined partial least squares (PLS) and MW modeling [9], and LWPLS is an extension of PLS based on locally weighted (LW) modeling, which is a type of JIT modeling [10]. We applied them to the datasets without and with FEDA, or with the proposed LST-FEDA.

Correlation coefficient (R) and root mean square error (RMSE) were used as evaluation metrics of their prediction performance. The number of target domain samples in LST-FEDA and hyper-parameters of each soft-sensor construction method were determined to minimize RMSE with three-fold time-series cross-validation [11]. In this study, the candidates of the number of target domain samples were $n = \{5, 15, 30, 60\}$. These numbers roughly correspond to a few days, a week, two weeks, and a month worth of data. We used cross-validation, and for both MWPLS and LWPLS, the number of samples was set to 5. The prediction performances during one month before and after process maintenance (January and April 2022) and a steady operation period (May to October 2022) and an entire period of each soft-sensor are summarized in Table II. The best performance for each evaluation metric is highlighted in bold.

In both MWPLS and LWPLS, the soft-sensors with LST-FEDA achieved higher prediction performance than the soft-sensors without and with the conventional FEDA. In comparison with the soft-sensor using the conventional FEDA, the soft-sensor using LST-FEDA and LWPLS improved R and RMSE by 46% and 13%, respectively; and the soft-sensor using LST-FEDA and MWPLS improved R and RMSE by 55% and 25%, respectively. The prediction results of soft-sensors constructed using LWPLS are shown in Figs. 3 - 5. The left figures show time-series trends, of which the horizontal axis represents the sampling time and the vertical axis represents the purity of the telomer intermediate. The red and blue lines represent the measured and predicted values, respectively. The right figures illustrate scatter plots, of which the horizontal and vertical axes

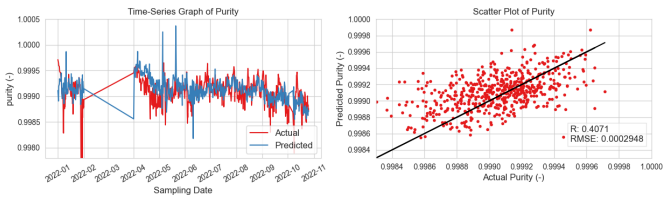

Fig. 3. Prediction result of soft-sensor using LWPLS without FEDA

TABLE II
PREDICTION PERFORMANCE OF SOFT-SENSORS

Soft-Sensor Construction Method	FEDA Application Method	One month before and after maintainance		Steady operation period		Entire period	
		R	RMSE ($\times 10^{-4}$)	R	RMSE ($\times 10^{-4}$)	R	RMSE ($\times 10^{-4}$)

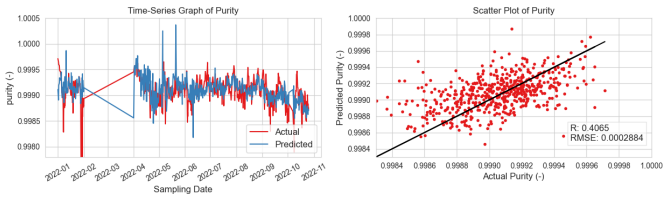

Fig. 4. Prediction result of soft-sensor with FEDA and LWPLS

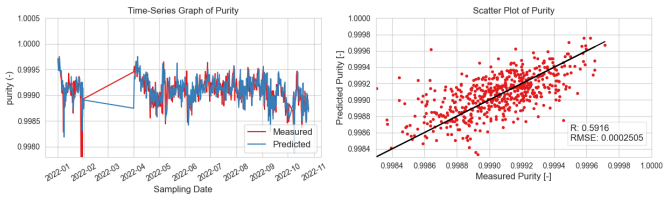

Fig. 5. Prediction result of soft-sensor with LST-FEDA and LWPLS

represent the measured and predicted values. These figures clearly show the usefulness of the proposed methods.

The performance improvement in one month before and after process maintenance suggests that the proposed LST-FEDA quickly and accurately adapted to changes in process characteristics caused by process maintenance. Moreover, the improvement of the prediction performance in the steady operation period suggests that LST-FEDA was able to deal with changes in process characteristics aging, or other factors because FEDA was not used in other methods during this period.

IV. Conclusion

In this study, we proposed a new adaptive soft-sensor construction method, LST-FEDA, which combines adaptive modeling and transfer learning. LST-FEDA continuously updates the definition of the target domain of transfer learning and constructs soft-sensors, which enables stable predictions without soft-sensor switching for preventing negative transfer.

We applied the soft-sensors based on the proposed LST-FEDA to the distillation process data including the maintenance periods and evaluated their prediction performance of the purity in the telomer intermediate. We confirmed that the proposed LST-FEDA improved the prediction performance during the steady operation period as well as the period before and after process maintenance in comparison with the conventional methods. It is indicated that the proposed method can construct soft-sensors applicable to both changes in process characteristics by process maintenance and changes in process characteristics by aging over time.

In future works, we will apply the proposed LST-FEDA to other real-process operational datasets to evaluate its performance. In addition, we will investigate whether dynamically adjusting the number of the target domain samples for each query sample, instead of using a fixed number to improve prediction performance.

***Abstract* — Wire bonding involves bonding of thin wires precisely, typically made of gold or aluminum, often comes with intricate connections. Inspection systems often have to be placed in manufacturing lines to check the bonding process as defects could be introduced, thus decreasing the yield of IC chips. A lack of proper inspection system to ensure the overall quality and reliability of these bonds could cause premature device failures and costly recalls. The current 2D inspection systems have limitations in analyzing wire bonding 3D defects, as it may not able to identify defects that occur in the vertical dimension or are hidden from the top-down view. In this paper, we present a method to detect wire bonding defects in point cloud on our self-generated wire bonding mock-up datasets, named WireBondMockUp. In this work, we investigate the performance of different widely used 3D object detection methods to localize wire defect area in the WireBondMockUp, using different network architectures such as 3DETR, VoteNet, MLCVNet, and H3DNet. Our WireBondMockUp were annotated using LabelCloud and being randomly split into training and evaluation tailored to imitate wire bonding defects. Experimental results show that 3DETR, with learning rate 0.001, 1440 epoch and batch size of 4 could achieved 92.42 % in F1-score detection accuracy. The inference time was 0.08351 seconds. Experimental results also showed that the 3DETR could detect wire bonding defects in point cloud, highlighting the strengths in improving yield for IC manufacturing.**

I. INTRODUCTION

The demand for smaller size electronics products has kept engineer to shrink the sizes of electronic circuit elements from micrometer to nanometer, to ensure the capacity of integrated circuits (IC) can meet the emerging electronics products functions[reference]. Manufacturing ICs has thus become one of the fastest-expanding technologies due to the demand for higher end electronic products. As IC sizes decrease, wire bonding has become a popular choice for making electrical connections within the IC packaging. However, the bonding process can be complex, and there exist many precise controls of various parameters in order to achieve reliable and high-quality wire bonds. As such, placing a reliable inspection system to visually inspect and detect defects accurately is crucial especially as wire bond size decreases. However, the current inspection system focuses on 2D images, detecting defects such as missing bonds, short circuits, wire loops, or lifted bonds[reference]. On the other hand, there is a strong demand to detect defects occurring in the vertical plane, such as tilted bonds, lifted bonds, or bond deformation, which may not be apparent from a top-down image captured.

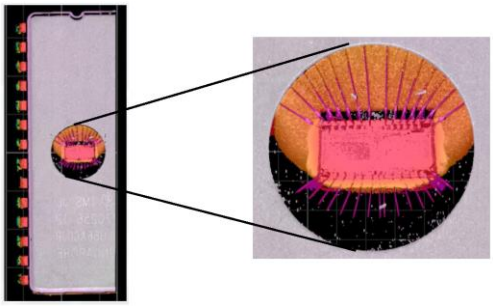

Fig. 1 Wire bonding

These days, the 3D object detection methods have shown remarkable performance on 3D public benchmark datasets [kitti, nuscene, waymo], but there is a lack of work reported for specific application domains. There exist limited reported implementation scenarios for specific industrial defects domain such as 3D defects detection, as it is relatively new and rapidly evolving. Nonetheless, as 3D imaging techniques could provide a detailed structure of the wires bonding structures, which permits the identification and analysis of defects, deploying 3D defect detection in manufacturing lines could prove to become a necessity, when manufacturing IC, to increase production yield.

In recent years, deep learning has gained significant popularity in the field of 3D object detection. Deep learning techniques have shown remarkable progress especially in detecting and localizing objects accurately in 3D space from different type of sensor inputs, such as LiDAR (Light Detection and Ranging) point clouds or RGB-D images [1-4]. In 2019, Qi et. al proposed VoteNet to detect objects in point clouds based

979-8-3503-0067-3/23/$31.00 ©2023 IEEE

on a Hough voting strategy [1]. In 2020, Xie et. al extends Votenet with additional three-level useful contexts into the voting and classifying stages to encode contextual information [2]. In 2020, Zhang et. al proposed a 3D object detection method by using the hybrid predicted geometric primitives and then fitting the detected objects to these primitives and their associated features [3]. In 2021, Misra et. al proposed a transformer-based detection method with versatile attention-based backbone which could preserve the vanilla transformer blocks to reach comparable performance with CNN-based detectors [4]. However, these works fail to provide details on their performance for self-generated dataset, especially applying them in industrial applications, such as detecting wire bonding defects, which involves achieving a balance between inference speed and limited training datasets. Moreover, conventional 3D vision inspection systems often rely on height measurements to detect failures in wire bonds, and the complex nature of wire bond structures makes it challenging to reliably detect defects for each individual wire.

Based on the above, in this paper, we are proposing generating a mock-up dataset for imitating 3D wire bond structures and present a comprehensive analysis, using the 3D object detection methods discussed above, on self-generated wire bonding mock-up datasets. Our aim is to provide a more comprehensive and accurate assessment of wire bond quality, ensuring that even intricate structures can be thoroughly examined for defects. Our work emphasizes the practicability of these methods and their strength based on a common implementation scenario, i.e., applying these methods directly on our own datasets, named WireBondMockUp. We believe that evaluating the performance of these methods on custom datasets is crucial to understand their real-world applicability and to bridge the gap between theoretical advancements and practical applications.

The main objectives of this paper are:

- To propose a strategy to study and create a wire bonding point cloud dataset.
- To propose a unified strategy to detect wire bonding defects.

The rest of this paper is as follows. The materials are presented in Section II. Section III describes the proposed methodology. Section IV discusses the experiment results and lastly Section V concludes the paper with future works.

II. MATERIALS

In recent years, significant advancements have been made in the techniques used to collect and analyze 3D datasets, catering to diverse requirements. The common experimental set-up could include a camera associated to a recording in a specified grid for selectivity trials – see Fig. 2. In creating our mock-up dataset, we first set-up a wire bonding scenario, i.e. with/out failed bonding – see Fig. 3.

Fig. 2 Acquisition materials (left) Intel RealSense™ D435 (right) wire bonding mock-sup set-up

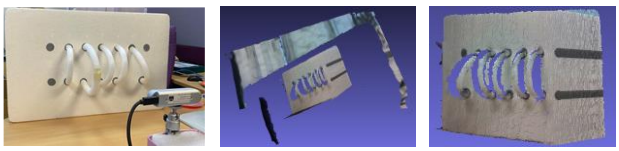

Fig. 3 Acquisition scenario (left) set-up (middle) uncropped (right) cropped

Then, an Intel RealSense™ D435 camera is mounted on a table top to record the scenario presented in the mock-up wire bonding set-up. Our acquisition scenario, with the above-mentioned set-up, notably produced: 1) some part of the point cloud which is required to be cropped, corresponding to the not-interesting objects around the wire bonding areas; 2) thin structure of the wire bond which may not work well with some 3D object detection method, and 3) artefacts appearing in the wire bonding area due to the camera and acquisition angle – see Fig. 3 for uncropped/cropped view. Our sample targets include detecting all wire bond and their associated defects such as tilted bonds, lifted bonds, or bond deformation – see Fig. 4.

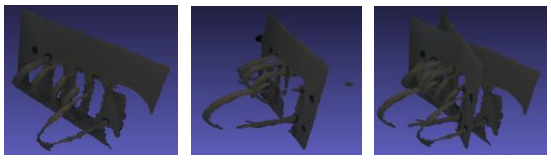

Fig. 4 Acquisition scenario (left) defect view1 (middle) defect view2 (right) comparison

The datasets include data collected from multiple viewpoints, ensuring a comprehensive coverage of the wire bonding defects. The resultant point cloud shows that in the experimental set-up, the RealSense camera is shifted to accommodate different

viewpoints highlight earlier. By offering wire bonding conditions from various viewpoints, we aim to enhance the robustness of our detection system.

TABLE I
DESCRIPTIONS OF TAG USED IN EXPERIMENTS

Tag	Description
accept	the wire bonding has no defects issue
reject	the wire bonding comes with defects such as tilted bonds, lifted bonds, or bond deformation.

In this work, we annotated the point cloud data using a graphical image annotation tool, named labelCloud, to outline and to label an object, in this instance as "reject" or "accept", with the bounding boxes drawn in order to extract label information used in the training process and export as .json file – see Fig. 5.

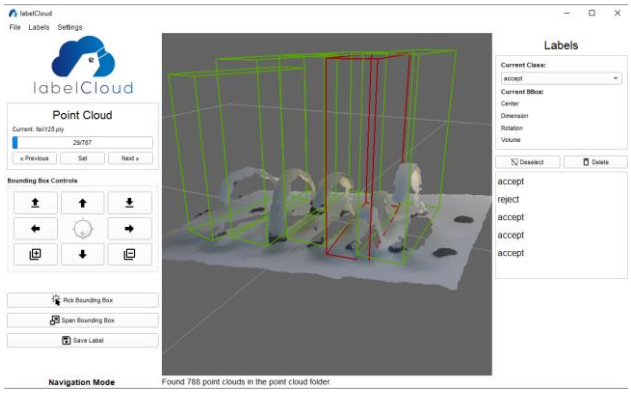

Fig. 5 labelCloud annotation

III. PROPOSED METHODOLOGY

In this section, we describe the methodology employed for evaluating the performance of the 3DETR, MLCVNet, H3DNet and VoteNet 3D object detection methods on our WireBondMockUp dataset – see Fig. 6. We highlight the key similarities and differences in their architectures, as well as the specific models used for our evaluation.

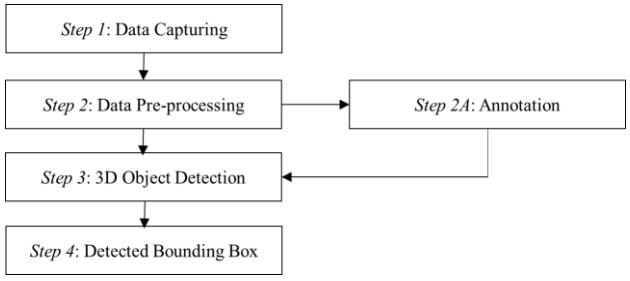

Fig. 6 3D Detection Pipeline

A. *Step1: Data Capturing*

The steps to obtain the WireBondMockUp was highlighted in Section II. A total of 800 3D point cloud data was collected. The annotation was completed for 170 3D point cloud data, used for training, while 34 is used for validation – see Fig. 7.

Fig. 7 WireBondMockUp train, test and validate dataset

B. *Step2: Data Pre-processing*

The 3DETR, MLCVNet, H3DNet and VoteNet 3D object detection methods accept point cloud data. The point cloud data is being converted based on the camera parameters, similar as used in VoteNet. The evaluation used the mean average precision(mAP) under different IoU thresholds, i.e., 0.25 and 0.5. The additional Step2A was detailed in Section II.

C. *Step3: 3D Object Detection*

We provide detailed descriptions of the specific models employed for our evaluation of the 3DETR, MLCVNet, H3DNet, and VoteNet methods – see Fig. 8. For each method, we outline the specific layers, modules, and parameter configurations for that model to accommodate the WireBondMockUp, in line with our evaluation objectives. We provide a comprehensive evaluation of the 3DETR, MLCVNet, and VoteNet methods on our self-generated datasets, highlighting both their shared architectural characteristics and distinct modeling choices in the discussion below.

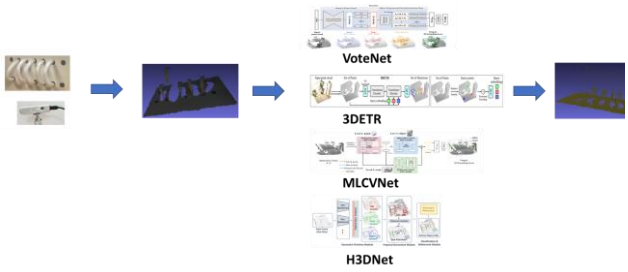

Fig. 8 Step3: 3D Object Detection [1-4]

VoteNet: VoteNet is presented by Qi et al. at 2019 and it is a point clouds based end-to-end 3D object detection algorithm using voting approach to estimate object's centre, bounding box and semantic classification. There are two major procedures has been highlighted in this VoteNet research: (1) point cloud feature learning through a backbone network and (2) learned Hough voting from seed points. For first procedure, they implement a deep network on point clouds for point

feature learning where the backbone of this deep network is constructed with multiple down-sampling (set-abstraction) layers and up-sampling (feature propagation) layers with skip connections and it outputs a group of seed points. The layers using this backbone network are from PointNet++ models [5]. Next, at the second procedure, each seed point generates a vote for centre coordinate of a bounding box through a shared multilayer perceptron (MLP). Then votes within a predefined radius distance are grouping and sampling to estimate the centroid of the object. Then bounding boxes and classification information are estimated around the predicted centroid of object through another shared MLP. All the estimated bounding boxes are filtering using 3D non-maximum suppression. The prediction outputs of this VoteNet including: an objectness score, bounding box parameters and semantic classification scores.

3DETR: 3DETR is presented by Misra et al. at 2021 and 3DETR is an end-to-end trainable Transformer that inputs 3D point clouds and outputs 3D bounding boxes. During training phase, this 3DETR uses a set-aggregation down-sampling operation from PointNet++ to reduce the number of points in point clouds [5]. Next the sampled points are set as input to Transformer encoder in order to produces a set of per-point features using self-attention layers. In the following, the output features from encoder and a set of 'query' embeddings are input to the Transformer decoder to predict bounding boxes using a parallel decoding scheme. For inference stage, the input point clouds are randomly sampled using Farthest Point Sampling [6] to generate a set of 'query' points and these that are embedded using Fourier positional embeddings [7] and pass to Transformer decoder. Then decoder takes this information and predicts centroid of object, bounding boxes and semantic classification, as well. There are five loss functions used in this 3DETR including: L1 regression losses for center and box dimensions (normalized in range [0,1]), Huber regression loss for angular residuals and cross-entropy losses for the angular and semantic classification. This 3DETR has been highlighted that it has the properties of simpler implementation and understanding by reducing many of the hard-coded design decisions in VoteNet and PointNet++, at the same time, it doesn't utilize ConvNet backbone in its architecture.

MLCVNet: MLCVNet is proposed by Xie et al. at 2020 and it is a 3D object detection network that alter the existing VoteNet algorithm by appending new self-attention and MLP modules to create a new framework which can capture and consider multi-level contextual information at patch, object and global scene levels. The contextual information at multiple levels in point clouds are captured using two self-attention modules and a multi-scale feature fusion module. As discussed by authors, it is important to employ multi-level contextual information for 3D object detection from colour-less and sparse point cloud data because it is difficult to identify the object when the point clouds appear independently, even for human naked eye. However, once there are extra information or knowledge from either surrounding environment or external domain, object recognition process will become relatively easier and this extra information is possible to be obtained from indoor scene, especially, due to indoor scene has specific man-made structural constraints or arrangement. The three important modules are highlighted in this research, which is patch-patch context (PPC) module, object-object context (OOC) module and global scene context (GSC) module. Their functionalities are explained as follows:

- Patch-patch context (PPC) module employs a self-attention layer to consolidate information from all the other point patches before sending it to the voting stage where the output point patch from this module contains not only its own local features, but also the information associated with all the other point patches
- Object-object context (OOC) module also employ a self-attention layer as well to capture relations between predicted objects where these predicted objects are in the form of vote clusters after voting stage as mentioned in VoteNet
- Global scene context (GSC) module extract the information from point patches and clusters using max pooling layers and concatenating them to form a global feature vector. Then this global feature vector is fed to an MLP to further aggregate the global information and this global information will be fused with the output from object-object context (OOC) module to generate final prediction result.

H3DNet: H3DNet is presented by Zhang et al. at 2020 as well. This H3DNet is an end-to-end 3D object detection network that inputs a dense set of 3D points (40000 points as proposed), predicts a group of geometric primitives (1 BB centers, 6 BB face centers, and 12 BB edge centers) with their latent features, then converts those information into object proposals and classifies each proposal as detected bounding box (BB center, BB size, and BB orientation, and a semantic label). There are three major components as discussed in this research:

- Geometric primitive module: A group of 3D points are fed into this module and this module predicts a set of geometric

primitives that includes locations of BB centers, BB face centers, and BB edge centers of the underlying objects

• Proposal generation module: This module inputs predicted geometric primitives and generates a set of object proposals where this object proposals are constructed as local minimums of a distance function, which is the innovate way as emphasized in this work.

• Classification and refinement module: This module classify each object proposal into a detected object and calculates offset vectors to refine the detected bounding box information (center, size and orientation) and a semantic label.The loss function of H3DNet uses L2 regression losses for geometric primitive location and shape, and uses cross-entropy loss for the rest, such as offset existence flag prediction, semantic labels.

D. Step4: Decision

The train model will be directly feed into the point cloud file for detection. For each detection, a counter is initialized with value 0 to keep track of how many objects detected. Objects detected can be viewed in sub folder, according to the configuration provided. The numbers of objects detected are displayed at the bottom, which corresponds to the number of the wire bond detected in the point cloud file – see Fig. 9.

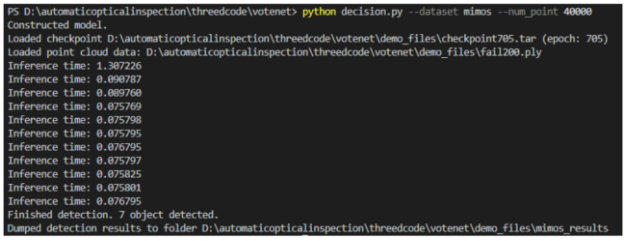

Fig. 9 Step4: Decision

IV. EXPERIMENTAL RESULTS

In this paper, we propose deploying different 3D object detection methods, such as 3DETR, MLCVNet, H3DNet and VoteNet, to study the WireBondMockUp datasets, which comes with different defects, in order to locate those defects accurately. Different methods could highlight the success or failure of the proposed architectures for the highly challenging dataset.

TABLE II
HYPERPARAMETER VALUE USED IN EXPERIMENTS

Hyperparameter	Description
Epoch	720
Batch Size	8 / 4 (3DETR)
Learning Rate	0.001
BN Decay Momentum	0.5
Platform (GPU)	NVIDIA GeForce RTX 2080

The performance of each method is determined by their precision and recall for the same testing set. All the experiments were performed on the same dataset for consistency, to provide a comprehensive evaluation of the methods on the WireBondMockUp, allowing for a fair and thorough comparison of their performance. – see Table II for more information.

A. Analysis1: General analysis on the model capability

In order to assess the performance of the 3DETR, MLCVNet, and VoteNet methods, we employ a set of hyperparameters used in the experiments – see Table II. A set of evaluation metrics shown in Table III, such as precision, recall, average precision, and Intersection over Union (IoU) are used to compare the performance of the method. We explain the significance of each metric in measuring the accuracy and robustness of the detection results.

During implementation, we encounter some deployment issues for each of the method. For VoteNet, generating own dataset proves to be a time-consuming task, as we have to familiarize with the format of the train and validation dataset. Though it is not superior in terms of performance, we found that VoteNet are able to support training, visualization and evaluation. For H3DNet, the main reason we select this method

TABLE III
PERFORMANCE COMPARISON ON DIFFERENT METHODS

Model	**Metrics**				**F1 score for 0.25**	**F1 score for 0.50**	**Inference (s)**
	mAP 0.25	**mAP 0.50**	**AR 0.25**	**AR 0.50**			
VoteNet[2019]	19.71	4.96	93.02	52.09	32.53%	9.06%	0.0788
MLCVNet[2020]	31.21	8.96	97.93	57.25	47.33%	15.50%	0.09175
H3DNet[2020]	0.0002	Not Available	0.8197	Not Available	0.03%	Not Available	Not Available
3DETR[2021]	64.35	17.76	88.31	40.55	74.44%	24.70 %	0.08351

is due to its ability to predict thin objects in 3D scenes. However, the performance on the WireBondMockUp may be influence by its computation limitation, having been able to execute only the single backbone due to the selected GPU (one GPU), and the wire bond structure 1) lacks of being a complete and solid object, and 2) poor planar structures. For MLCVNet, its performance is better than VoteNet due to its three sub-modules ability in 1) gathering data when data is missing, 2) gathering contextual information of object candidates, and 3) gathering global scene context. However, though the performance is superior than VoteNet, the performance for detecting "reject" and "accept" may be limited by this contextual information, as the structure of the "reject" part and "accept" part are quite similar. Through these extensive experiments, we show 3DETR outperforms VoteNet, MLCVNet and H3DNet. In terms of implementation, 3DETR is conceptually simple and easy to implement. The non-parametric queries and Fourier encodings techniques are able to detect the point clouds as they are irregular and sparse.

B. Analysis2: Further analysis on 3DETR loss and training performance

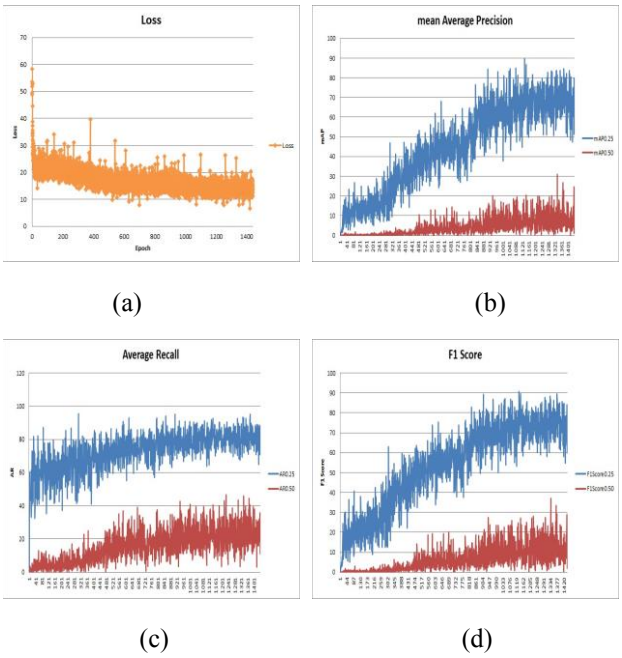

Fig. 9 Training performance of 3DETR on WireBondMockUp

In this further analysis, we explore the capability of 3DETR when we further trained the model – see Table IV.

TABLE IV
HYPERPARAMETER VALUE AND ACCURACY ACHIEVED IN THE EXPERIMENTS

Hyperparameter	Description
Epoch	1440
Batch Size	4
Learning Rate	0.001
BN Decay Momentum	0.5
Platform (GPU)	NVIDIA GeForce RTX 2080
mAP 0.25	90.85
mAP 0.5	22.11
AR 0.25	94.05
AR 0.5	41.23
F1 score for 0.25	92.42
F1 score for 0.5	28.78

The performance continues to increase when trained longer. The transformers-based 3D detection outperformed the traditional 3D object detection methods. As discussed in 3DETR publication, our experiment validated that 3DETR is capable to incorporate the inductive bias from irregular and incomplete points clouds from our WireBondMockUp dataset and perform accurate bounding box detection.

V. CONCLUSIONS

The recent rise in the popularity of deep learning has sparked interest among many in the field of machine learning. Not only does it outperform traditional machine learning techniques, but deep learning has also rapidly garnered a lot of attention and become a key technology behind many recent applications. These findings have motivated many products, especially in defect analysis, to embark on deploying deep learning tools in their product. Our self-generated datasets, named WireBondMockUp are able to capture component structures, capturing variations in object types, orientations, and occlusion levels that are relevant in the study. It is important to note that our work emphasizes the practical relevance by providing implementation scenarios and applying these methods directly on the WireBondMockUp. This work proposed to investigate the performance of the four 3D object detection methods which comes with different network architectures, on the WireBondMockUp. Experimental results indicate that extending the training epoch to 1440 for 3DETR shows that it could outperformed other architectures, achieving 92.42% in F1-score accuracy.

ACKNOWLEDGMENT

‡ Institute for Infocomm Research, A*STAR, Singapore

***Abstract*—Cognitive Behavioural Therapy (CBT) is a well established method for treating clinical depression. However, it is only considered successful for roughly half of those receiving it. Transitioning patients who are unlikely to benefit from CBT to alternative treatments, at an early stage, can significantly enhance their quality of life while alleviating the burden on mental health services. This study focuses on predicting the outcome of CBT using Linear Discriminant Analysis (LDA) models. These models are trained using demographic information, as well as data from depression (PHQ-9), anxiety (GAD-7), and functional impairment (WSAS) questionnaires administered during the initial four CBT sessions. The study aims to determine how the accuracy of the prediction models is influenced by different factors, such as the number of therapy sessions considered, the specific questionnaires used, and the analysis of individual symptoms versus the overall questionnaire scores. The data from over 8000 patients receiving high-intensity CBT (step 3 and 4) is analyzed. Prediction models are trained using different combinations of features and validated across multiple theray sites to ensure generalizability. The best performing model achieved a test accuracy of 69.7% (Odds Ratio OR = 5.20) in predicting whether Reliable and Clinically Significant Improvement (RCSI) was achieved. Interestingly, including baseline scores, demographic information, and WSAS/GAD7 data did not significantly improve the accuracy beyond using PHQ9 responses alone. However, incorporating data from successive therapy sessions consistently improved the prediction accuracy, up to a maximum of four sessions (the limit of the analysis). Surprisingly, analyzing individual symptom trajectories did not offer any advantages over analyzing the total scores of the questionnaires. In conclusion, the study demonstrates that monitoring responses to therapy during the initial sessions can be a valuable tool in predicting treatment outcome. Although there were significant correlations between RCSI and symptom level change, the study found no improvement in the model's prediction accuracy when considering: (1) individual symptom scores instead of the overall questionnaire score, (2) using GAD-7 and WSAS questionnaires in addition to PHQ-9, or (3) including demographic information.**

I. Introduction

Clinical depression, one of the leading contributors to global disability burden [1], can be debilitating, draining all motivation and pleasure from life, and in severe cases contributing to suicide. Co-morbidities are common - depression complicates care and worsens prognosis for conditions as varied as cancer [2], schizophrenia [3], and heart disease [4]. One of the most effective treatments for clinical depression, Cognitive Behavioural Therapy (CBT), is a talking therapy focused on interactions between thoughts, feelings, and behaviours. However, CBT still only appears to be successful in around half of patients - e.g. in the dataset analysed in this paper, 53.9% of patients achieved Reliable and Clinically Significant Improvement (RCSI).

This study was designed to predict which patients undergoing CBT are likely to achieve RCSI as measured using the Patient Health Questionnaire 9 (PHQ-9) [5], and determine which of the demographic, self-report questionnaire, and symptom information available were most important in making these predictions. Using such outcome prediction models, patients determined to be unlikely to achieve RCSI during CBT may be offered more individualised treatment plans, by way of alternate therapists, therapy styles, or treatments. This could lead to higher chances of recovery, enhancing their quality of life and reducing burden on mental health services.

Some studies have shown that prediction of psychological therapy outcomes can be made even before the first session. Finegan et al, in a review of socio-economic status and psychological therapy outcomes for depression and anxiety, found unemployment, low income, and relative neighbourhood deprivation to be indicators of poor therapy outcome, whereas social class and educational level were not found to be good predictors [6]. Huibers et al. used five predictors (gender, employment status, anxiety, personality disorder and quality of life) and six moderators (somatic complaints, cognitive problems, paranoid symptoms, interpersonal self-sacrificing, attributional style and number of life events) to make recommendations for depressed patients for choosing either cognitive therapy (CT) or interpersonal psychotherapy (IPT) [7]. Some features indicated good prognosis for both therapies (employment, low anxiety, female gender), while others were more common in those for whom a specific therapy style was more likely to be effective [7].

The therapist also affects outcome. The 'Common factors', including therapist empathy, alliance, cultural adaptation, and therapist effects have an impact on treatment [8]. In addition, the therapist's facilitative interpersonal skills [9], self-doubt

979-8-3503-0067-3/23/$31.00 ©2023 IEEE

[10], and humour style [11] are important, as is the frequency and regularity of therapy, with weekly being better than less frequently [12].

Once therapy has commenced, there is consistent evidence that early symptom change is a reliable indicator of eventual remission. A recent systematic review and meta-analysis investigated the link between early responses to psychological therapy and treatment outcomes for depression and anxiety, finding that early responders had significantly better post treatment outcome, with a large overall effect size of early response on final outcome (g = 0.87, Odds Ratio OR = 4.84) [13]. While study designs and definitions varied across included trials, results were strong and consistent, and the authors stressed the importance of regularly monitoring a patient's symptoms.

We found no studies explicitly analysing changes in individual symptoms (rather than overall symptom score), but some symptoms of depression, such as insomnia, are studied in the context of being a co-morbidity. For example, Bei et al. used growth mixture modelling on overall levels of depression on 148 patients with insomnia and major depressive disorder (MDD) [14]. They linked symptom trajectories to insomnia, claiming early changes in insomnia may predict long-term depression outcomes.

Consequently, in this study we aim to investigate whether CBT outcome can usefully predicted in an early stage of therapy. Critically, we extend on previous work by investigating the utility of individual symptoms rather than overall level of depression, and which symptom questionnaires are most useful for outcome prediction models. As discussed, demographic information about the patient has demonstrable relationships to therapy outcome [6], but to what extent can this help a prediction model, and for how long is it still helpful when also tracking symptoms? This study has been designed to address these as yet unanswered questions by training Linear Discriminant Analysis (LDA) outcome prediction models on data from over 8800 patients receiving Cognitive Behavioural Therapy (CBT) at Improving Access to Psychological Therapy (IAPT) sites across England. This is a large and demographically diverse dataset, with the ability to cross-validate across IAPT sites across England, ensuring our models generalize well. These models were trained on different subsets of the available questionnaire and demographic data to answer the following questions. To the best of our knowledge, only the first of these five questions has been investigated explicitly by other researchers. Each has practical clinical use.

1) **How accurately can the proposed model predict success of CBT by tracking early symptom changes?** Calculating accuracy of the models trained will allow us to determine the utility of symptom tracking to mental health services.
2) **How does the proposed model's prediction accuracy change with each additional session of therapy analysed?** Participants filled in symptom questionnaires at each session of therapy, and we varied the number of therapy sessions included in training the prediction models from 0 (including only demographic information and baseline scores) up to 4.
3) **Which questionnaires and their derived features are key for outcome prediction by the proposed model?** We will restrict our prediction models to different questionnaires (out of PHQ-9, GAD-7, and WSAS) and combinations thereof, allowing us to assess the impact on the prediction accuracy.
4) **Does tracking individual symptoms offer any advantage to the proposed model over tracking the total symptom score?** We aim to expand on results of previous studies by comparing the use of total symptom level (i.e., PHQ-9 score) with individual symptoms (i.e. responses to each question item on the PHQ-9) in terms of achieved prediction accuracy.
5) **Does including demographic information improve the proposed model's prediction accuracy?** Demographic information alone has been shown to be useful in predicting therapy outcome [6]. Here, we aim to investigate to what extent its inclusion in prediction models can improve accuracy when tracking symptom scores.

II. Methodology

A. Participants and Treatment

Data were collected from 8865 (female = 5787, male = 3065, not available = 12) patients with a primary diagnosis of either 'depressive episode' or 'recurrent depressive disorder' who had attended at least 4 sessions of high intensity (Step 3 or 4) CBT. Patients were from 16 Improving Access to Psychological Therapy (IAPT) [15] Services across 7 Sites in the United Kingdom between 2010-2015. Sessions were 1-to-1, typically lasting an hour each. Patients had on average 12.7 (±5.0) sessions of CBT. Some patients had been on lower intensity group therapy sessions (Step 2) prior to step 3 or 4 - responses to questionnaires during step 2 were not included in this analysis.

Exclusion Criteria. Patients for whom RCSI was not calculable (beginning therapy with PHQ-9 score below 10, or no PHQ-9 data at either baseline or final therapy session) were removed, after which the dataset consisted of 8027 patients. Note that many of these removed patients still had calculable PHQ-9 change, and statistical tests involving PHQ-9 change were done on the larger sample of 8862 patients. Please see the section on *Outcomes*, for more details on how RCSI is calculated and why the baseline PHQ-9 score of less than 10 was an exclusion criteria.

B. Measures

Demographic Data. In this study, demographic data consists of gender, age, ethnicity, employment status, 2015 IMD (Index of Multiple Deprivation) decile of the region the patient lives in [16], whether the patient is taking medication, the presence of any long-term health conditions, and the presence of any disabilities. All these categories apart from age and IMD decile have been binarised for all proceeding analyses, i.e, female or male, White or Non-White, employed or unemployed,

taking medication or not taking medication, long term health condition or no long term health condition, disability or no disability. These variables are all taken at the first assessment by a general practitioner (GP), before therapy had started.

Symptom and Questionnaire Data. Baseline levels were included for the three following questionnaires at initial assessment with a GP. Additionally, responses to each of these questionnaires were recorded at each session of therapy. All were self-report Likert-type scales.

- **PHQ-9** The Patient Health Questionnaire 9 is a nine-item tool for screening, diagnosing, monitoring, and measuring the severity of depression. The PHQ-9 questions are based on diagnostic criteria of depression from DSM-IV (Diagnostic and Statistical Manual of Mental Disorders) and ask about the patient's experience in the last two weeks [5]. Questions ask the patient "Over the last two weeks, how often have you been bothered by any of the following problems?", with four possible responses ranging from "Not at all" (score of 0) to "Nearly every day" (score of 3). A score of 10 or above has a sensitivity of 88% and a specificity of 88% for detecting major depression [5].
- **GAD-7** The Generalized Anxiety Disorder 7 is a seven-item that is used to measure or assess the severity of general anxiety disorder (GAD) [17]. Each item asks the individual to rate the severity of their symptoms over the past two weeks. Response options include "not at all", "several days", "more than half the days" and "nearly every day". GAD-7 shows excellent internal consistency and good test-retest reliability [17].
- **WSAS** The Work and Social Adjustment Scale is a five item scale assessing the impairment a patient feels as a result of a health condition [18]. This questionnaire includes five questions assessing impact of a condition on the patient's work, personal, and social life. Questions are of the form "Because of my [problem] my [. . .] is impaired. '0' means 'not at all impaired' and '8' means very severely impaired to the point I can't [...]."

Treatment Outcome. Full recovery from depression was defined as moving to below the clinical cutoff score of 10 points and more than 6 points of change on the PHQ-9 questionnaire. This standard is known as Reliable and Clinically Significant Improvement (RCSI), which is a widely accepted measure of recovery [19]. PHQ-9 scores used to determine RCSI were those taken at the initial assessment with the GP (i.e. before any session of therapy), compared with PHQ-9 score taken at the final session of the attended therapy.

Statistical Tests for Feature Comparison. Statistical analysis of the individual features were not the purpose of this paper and will not be commented on in depth. It was still informative to perform some statistical analysis on the features used. These tests in no way influenced the model training process. Tables I, II give some of these statistics, with the majority omitted for conciseness.

We considered ANOVA tests unsuitable, due to the large amount of dependency between features. We calculated rank biserial correlation (RBC) using the MES toolbox [20] in MATLAB between each of the symptom based features and the dichotomous outcome of RCSI or no RCSI. We also calculated Kendall correlation between each of the calculated features and overall PHQ-9 change during the analysed therapy sessions. The same was performed to compare the overall PHQ-9 change against age and IMD decile, the only nominal demographic data. For the categorical demographic data, we calculate Phi correlation with RCSI and Kendall correlation with PHQ-9 change. Appropriate p-values are calculated for each. Each of the tests used are non-parametric, allowing for fairer comparisons between features with different distributions.

C. Model Training

Prediction models were trained to determine whether RCSI was achieved or not by end of treatment, with cross-validation across different IAPT sites.

Feature Extraction. Responses to each question from PHQ-9, GAD-7 and WSAS from the first $0 \leq n \leq 4$ sessions of therapy were analysed. The mean, the slope, the root mean squared error (RMSE) from the slope, and the standard deviation (SD) of the first n sessions of each question as well as the summed total for each questionnaire were used as the features of the prediction model. RMSE and SD are similar but distinct variables - SD tells us the overall variability in a patient's symptom, while RMSE tells us how closely symptom change follows a linear slope. To calculate the mean, we needed at least one session of therapy. To calculate slope and SD, we needed at least two sessions, and RMSE requires at least three. For the sake of simplicity and ease in interpreting the results, we did not extract more complex non-linear features.

Splitting Data for Testing and Training. Our models were evaluated with cross-validation, whereby the data are split into distinct 'folds' for training and testing. Prediction models are trained on all but one fold of the data, and tested on this 'test fold'. This process is repeated until each fold has been the test fold exactly once, and the aggregated results from each test fold are reported.

The dataset includes data on patients from seven IAPT Sites across the UK, of unequal sizes. To get more evenly distributed cross-validation fold sizes, we merged the three smallest Sites into one, and divided the largest Site in two (this division still maintained distinction between Services within the Site). This resulted in 6 folds, of sizes 1263, 961, 1685, 1042, 1698, and 1378, respectively. From a machine learning perspective, the unequal split is not ideal, but we considered it important to demonstrate generalisation across IAPT sites, and regard this as a key strength of this paper.

Replacing Missing Data. With such a large dataset of this type missing values are inevitable. Missing continuous values in each test and train fold are replaced by the mean of each feature in the train fold. Missing categorical values are replaced by the mode in the train fold. To avoid biasing the results, we needed to make sure training data and model training do not have any dependency on the test data. Thus, replacing missing

values was done only based on the information from the train data. In a real-world application, the data used to train the model would also be used to estimate missing values in the testing data.

Training and Testing Prediction Models. Linear Discriminant Analysis (LDA) models were trained separately on a variety of feature subsets. LDA classifiers create a hyperplane in feature space separating the classes – RCSI or no RCSI. Feature subsets are characterised by

- Questionnaire data from how many sessions of therapy are included in analysis, from 0 to 4 (5 choices)
- Which subset of questionnaire data (including or excluding each of PHQ-9, GAD-7, and WSAS) are used in analysis, using at least one of the three questionnaires (7 choices)
- The use of summed total scores alone for each questionnaire, or individual symptom scores (2 choices)
- The inclusion or exclusion of demographic information (2 choices)

This results in $5 \times 7 \times 2 \times 2 = 140$ potential feature subsets for comparison, across 6 folds. LDAs, which are computationally cheap to train, were chosen so we could quickly compare results from this large number of feature subsets.

Permutation test. To guarantee the fairness of our methods we evaluated our training procedure by randomising the outcome variable (PHQ-9 RCSI) and then performed the exact same model training and evaluation method for each feature subset 100 times. The resulting models had mean accuracies (per feature subset) between 49.5% and 50.4%, with standard deviations of at most 2% - i.e, we are confident the models performed at random chance level (for binary classification). This is strong evidence that any prediction accuracies reported are a result of relationships within the data and not methodological biases.

III. Results

We present the results as answers to the research questions given in the introduction. For each, we consider the principle of selecting the most parsimonious model within one standard error (SE) of the highest performing model [21] - i.e., does including a subset of features improve prediction accuracy by at least one standard error? With many different feature subsets, it can be difficult to decide which is the simplest model – therefore we have selected two within one standard error of the best performing model. All classification accuracies given are the weighted mean accuracies of the test folds, with weighted standard error.

A. How accurately can the proposed model predict success of CBT by tracking early symptom changes?

The best performing outcome prediction model achieved 69.7% (±0.61) test accuracy, with Odds Ratio OR = 5.20. This model was trained on all three questionnaires, included demographic information, and did not use individual symptom scores. Models with no symptom tracking, based solely on demographic information and symptom level at initial assessment, (shown by those at 0 sessions of therapy in Figs. 1–3) achieved at most 60.8% (±0.72) accuracy (OR=2.38) when using all 3 questionnaires and demographic information.

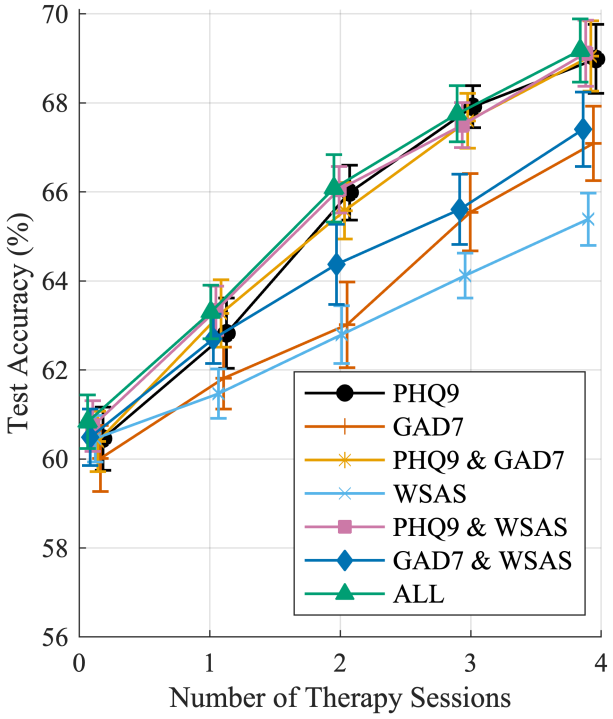

Fig. 1. Cross-validated mean test accuracy for prediction of RCSI with standard error bars against number of therapy sessions analysed, for a range of feature subsets. Mean and standard error are appropriately weighted by fold size. We can see the inclusion of questionnaires other than the PHQ-9 doesn't significantly improve prediction accuracy. For each symptom questionnaire combination in this figure, models include demographic information and use individual questionnaire responses.

B. How does the proposed model's prediction accuracy change with each additional session of therapy included in the model?

We found that, for each feature subset, increasing the number of analysed sessions improved prediction accuracy. For the best performing models, accuracy increased most during the first 2 sessions, from at most 60.78% (±0.72) to at most 66.08% (±0.77) and continued increasing to at most 69.7% (±0.61) by session 4. Inclusion of each subsequent therapy session in analysis had a mean accuracy greater than one SE from the previous mean accuracy. Figs. 1-3 show this effect.

C. Which questionnaires and symptoms are the most important for outcome prediction by the proposed model?

We found weak evidence for additional benefit of including WSAS or GAD-7 compared to PHQ-9 alone at either baseline or at any session monitored. This is evidenced by strong overlap in SE bars seen in Fig. 1. Given RCSI is determined by change in PHQ-9, it is no surprise that PHQ-9 was the most important for outcome prediction. Removal of PHQ-9 from session 2 onwards resulted in mean accuracy decreasing

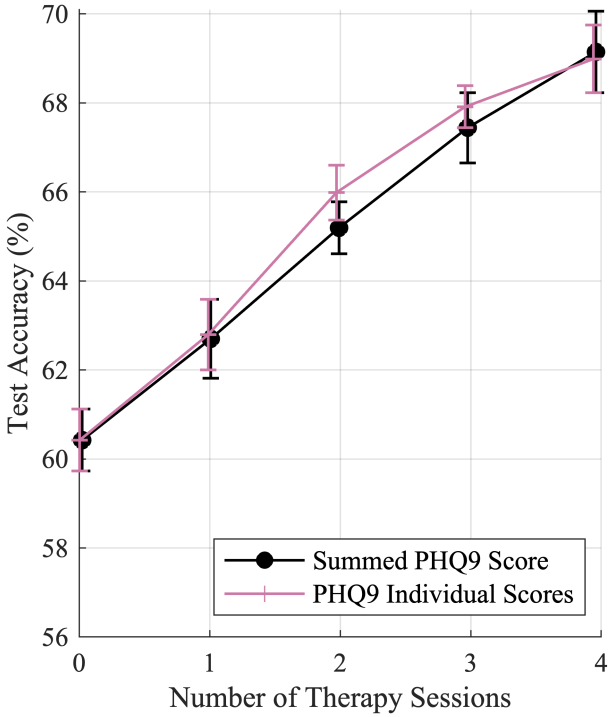

Fig. 2. Cross-validated mean test accuracy for prediction of RCSI with standard error bars against number of therapy sessions analysed. 'Summed PHQ9 Score' represents models trained only on total PHQ-9 score features, 'PHQ9 Individual Scores' represents models trained on features from all PHQ-9 questions. We see no significant benefit to the extra information from using individual questions rather than total score. Demographic information is included for the models in this figure.

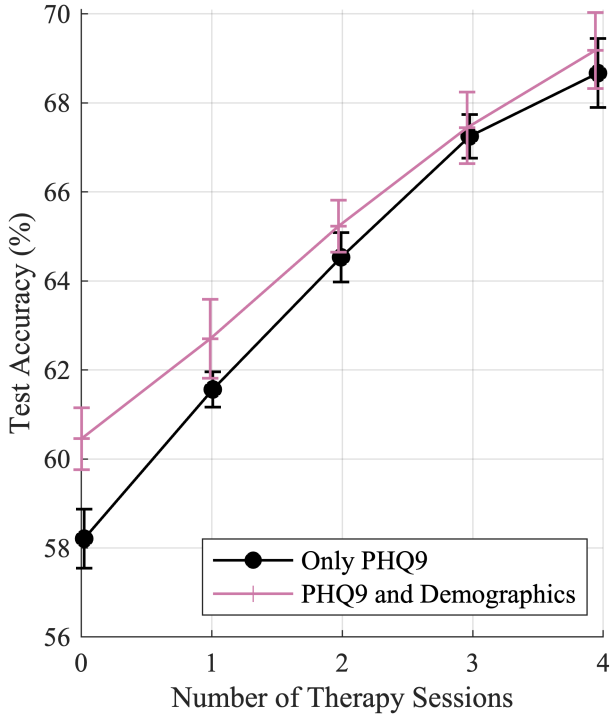

Fig. 3. Cross-validated mean test accuracy for prediction of RCSI with standard error bars against number of therapy sessions analysed. We see the benefit of including demographic information decays as more sessions are included. Individual PHQ-9 responses are used for the models in this figure.

by more than one SE as seen in Fig. 1. It is interesting that only small improvement to prediction accuracy was found by including either GAD-7 or WSAS, despite each individually achieving prediction accuracies of 67.41% (±0.75) and 65.39% (±0.52) respectively.

WSAS was used for one of the most parsimonious models within 1 SE of the best performing, achieving 69.05% (±0.77) with individual response scores and no demographic information. GAD-7 was used in the best performing model, but in neither of the most parsimonious models within 1 SE of the best performing. In Table I we can see that RBC against RCSI for WSAS baseline score (-0.170) is stronger than that of PHQ-9 baseline score (-0.141). Features calculated on 4 sessions of therapy [1] consistently show PHQ-9 features are the best performing for predicting both RCSI and PHQ-9 change, though many GAD-7 and WSAS derived features perform well. The features with strongest RBC against RCSI were consistently mean of the first four sessions, with higher mean making RCSI less likely. These were followed by slope features, with a steeper slope indicative of a higher chance of RCSI. A higher standard deviation and, to a lesser extent, higher RMSE from the slope, were indicators of achieving RCSI, with the most notable exceptions of PHQ-9 Q8 and Q9.

[1]At 96 features, we were unable to include this table in this paper

D. Does tracking individual symptoms offer any advantage to the proposed model over total symptom score?

Little evidence was found that including individual responses of the self-reported questionnaires added any benefit to the models over tracking total scores for each questionnaire. Fig. 2 shows consistent strong overlap in SE bars when we compare individual symptom analysis with total score. This is contrary to our expectations that a more detailed profile of a patients change in symptoms would help prediction accuracy. However, individual responses were used in one of the most parsimonious models within 1 SE of the best performing, achieving 69.05% (±0.77) when using PHQ-9 and WSAS responses.

E. Does including demographic information improve the proposed model's prediction accuracy?

Including demographic information in the analysis initially improves prediction accuracy by around 2%. As more sessions were included, we see the prediction accuracies converged, and by session 4 there was overlap in SE bars, visible in Fig. 3. Of the demographic features, only employment (φ= -0.193 RBC = 0.101) and disability (φ= 0.146) had effect sizes with absolute value > 0.1 (although the majority were statistically significant). In our dataset, disability had extremely high rates of missing values, so it's use in prediction is

TABLE I

RANK BISERIAL CORRELATION (RBC) AGAINST RCSI AND KENDAL CORRELATION (τ) AGAINST OVERALL PHQ-9 CHANGE FOR AGE, IMD DECILE (THE ORDINAL DEMOGRAPHIC FEATURES) AND BASELINE SCORES FOR THE THREE QUESTIONNAIRES. PHQ-9 RCSI AND CHANGE ARE CALCULATED BY THE DIFFERENCE BETWEEN FIRST AND FINAL SESSION OF THERAPY. NOTE THAT WHEN CALCULATING EFFECT SIZES FOR PHQ-9 CHANGE, SOME PATIENTS FOR WHOM RCSI WAS NOT CALCULABLE (E.G STARTING VALUE OF PHQ-9 TOO LOW) WERE INCLUDED. RCSI IS ENCODED AS 0 FOR NO RCSI AND 1 FOR RCSI.

Feature	RBC	p-value	τ	p-value
Age	-0.037	<0.001	-0.004	0.587
IMD decile	0.064	<0.001	-0.000	0.978
PHQ9 first	-0.141	<0.001	-0.289	<0.001
GAD7 first	-0.099	<0.001	-0.159	<0.001
WSAS first	-0.170	<0.001	-0.075	<0.001

likely less than suggested by the φvalue. One of the most parsimonious models within 1 SE of the best performing included demographic information and summed total PHQ-9 score, with accuracy of 69.18% (±0.71).

F. Summary

Tracking early symptom levels with the PHQ-9 questionnaire during CBT therapy is a promising tool in predicting outcome. We have demonstrated the use of adding each successive session of therapy, up to 4. The most parsimonious models with mean accuracies within 1 SE of the top performing model (69.67%±0.61) were trained on either (1) PHQ-9 total score and demographic information (69.18%±0.71) or (2) PHQ-9 and WSAS individual scores (69.05%±0.77). Models trained on just PHQ-9 score achieved 68.88% (±0.68) and 68.69% (±0.68) when using individual question responses or summed total respectively.

IV. DISCUSSION

A. Interpretation

Increasing accuracy with each successive session of therapy included in model training is as expected – the more sessions of therapy analysed, the clearer the prediction of the final outcome is. Contrary to what was predicted, analysing individual symptom trajectories gave little advantage when compared to summed symptom score, despite features derived from some individual questions, such as PHQ-9 Q2, having relatively strong effect sizes for both RCSI and symptom level change.

Similarly, while it was anticipated that models trained on PHQ-9 would outperform models trained on GAD-7 or WSAS, it was unexpected to find that adding GAD-7 and WSAS features to PHQ-9 features only resulted in a slight increase in outcome prediction accuracy. This is even more surprising because not only did many features derived from GAD-7 and WSAS exhibit similar or even better performance to those derived from PHQ-9 (in terms of correlation with CBT outcomes). For instance, GAD-7 total std (RBC = 0.212) demonstrated better correlation results compared to PHQ-9 total std (RBC = 0.198), and WSAS baseline score (RBC = -0.170) outperformed PHQ-9 baseline (RBC = -0.141).

TABLE II

PHI (φ) CORRELATION AGAINST PHQ-9 RCSI AND RANK BISERIAL CORRELATION (RBC) AGAINST PHQ-9 CHANGE FOR BINARY DEMOGRAPHIC FEATURES. RCSI AND PHQ-9 CHANGE ARE CALCULATED BY THE DIFFERENCE BETWEEN THE PHQ-9 SCORES OF THE FIRST AND FINAL SESSION OF THERAPY. NOTE THAT WHEN CALCULATING EFFECT SIZES FOR PHQ-9 CHANGE, SOME PATIENTS FOR WHOM RCSI WAS NOT CALCULABLE (E.G STARTING VALUE OF PHQ-9 TOO LOW) WERE INCLUDED. RCSI IS ENCODED AS 0 FOR NO RCSI AND 1 FOR RCSI. THE BINARY DEMOGRAPHIC FEATURES ARE ENCODED IN THE ORDER GIVEN IN THE TABLE AS 0 AND 1 RESPECTIVELY, WITH CLASS SIZES GIVEN (E.G, FOR GENDER, FEMALE (N=5787) IS ENCODED AS 0 AND MALE (N=3065) AS 1. φ=-0.025 SUGGESTS MALE PATIENTS ARE LESS LIKELY TO ACHIEVE RCSI AND RBC = 0.027 SUGGESTS MALE PATIENTS HAVE LESS OF A DECREASE IN PHQ-9 SCORE – NOTE HOWEVER, BOTH OF THESE EFFECT SIZES ARE VERY SMALL).

Feature	φ	p-value	RBC	p-value
Gender				
Female = 5787	-0.025	0.024	0.027	0.010
Male = 3065				
Ethnicity				
Non-white = 1614	0.029	0.010	0.002	0.832
White = 6872

Employed = 5986	-0.193	<0.001	0.101	<0.001
Unemployed = 2558				
Medication				
No Medication = 4204	-0.046	<0.001	-0.028	0.012
Medication = 3824				
Long Term Condition (LTC)				
LTC = 2587	0.089	<0.001	-0.037	0.001
No LTC = 4645				
Disability				
Disability = 355	0.146	<0.001	-0.074	0.002
No Disability = 1399				

The initial advantage of incorporating demographic information in the prediction model aligns with previous research findings, as expected. Notably, to our knowledge, our study is the first to demonstrate the diminishing impact of demographic information over time. Our study showed that relying solely on PHQ-9 is insufficient to achieve prediction accuracies within 1 standard error of the top-performing model. However, the inclusion of either (1) PHQ-9 total score and demographic information (69.18%±0.71) or (2) both PHQ-9 and WSAS individual scores (69.05%±0.77) were two of the most concise and effective models.

B. Strengths and Limitations

Modelling Assumptions. Statistical analysis of subjective, self-report, Likert scales is fraught with difficulty. Our feature extraction process assumes a linearity in score differences (e.g that the difference between '0' and '1' is the same as between '2' and '3'), which almost certainly oversimplifies and misses nuance.

Additionally, some of the assumptions required for LDA classifiers to function optimally were violated. The features included in the model did not follow gaussian distributions closely, and there is a large amount of correlation between features. However, these are not requirements to use an LDA classifier, and we are satisfied with the performance of our models.

In this study a simple model training procedure was used, with the emphasis on comparing the effects of different subsets of data rather than aiming to maximise accuracies. It remains possible that sophisticated models, which can more accurately capture interactions between features, may find benefit in including information our models did not require.

Generalisation. A key strength of this study was the use of a large dataset, with the ability to cross validate over different Sites and Services - there was never overlap in the IAPT Services on which models were trained and tested. This is an important, yet rare, element of our research which greatly strengthens our confidence that the results generalise well. Our best Odds Ratio was 5.20, larger than the mean of 4.84 found by Beard and Delgadillo in their 2019 review [13].

C. Implications for research, theory, and practice

We recommend more research and refinement of models before clinical use. This is a preliminary study demonstrating the potential of symptom tracking and investigating which subsets of information are most valuable to our models for predicting treatment response. Informed by this, we expect a more sophisticated model to achieve higher accuracies.
